A DICTIONARY

OF

UNIVERSAL KNOWLEDGE

NEW EDITION

VOL. VI

HUMBER TO MALTA

WILLIAM & ROBERT CHAMBERS, LIMITED

LONDON AND EDINBURGH

J. B. LIPPINCOTT COMPANY, PHILADELPHIA

1901

All Rights reserved

The following Articles in this Volume are Copyrighted by J. B. LIPPINCOTT COMPANY in the United States of America :

IDAHO.

ILLINOIS.

INDIAN TERRITORY.

INDIANA.

IOWA.

IRVING, WASHINGTON.

JACKSON, ANDREW.

JEFFERSON, THOMAS.

JOHNSON, ANDREW.

KANSAS.

KENTUCKY.

LEE, ROBERT EDWARD.

LINCOLN, ABRAHAM.

LONGFELLOW, HENRY WADSWORTH.

LOUISIANA.

LOWELL, JAMES RUSSELL.

MAINE.

Among the more important articles in this Volume are the following:

HUME, DAVID.....	J. HILL BURTON.	KEAN; KEMBLE.....	ROBERT W. LOWE
HUNGARY.....	BARBOLOMIEW GUNSZT.	KEATS.....	F. T. PALGRAVE.
HUNT, LEIGH.....	F. HINDS GROOME.	KEBLE.....	REV. PROF. W. LOCK.
HUSBAND AND WIFE.....	THOMAS RALEIGH.	KENT; LINCOLN.....	J. C. GROOMIE.
HYDRODYNAMICS.....	Professor CARROLL G. KNOTT.	KENTUCKY.....	Professor FRANK B. GREENE.
HYDROGEN.....	Dr L. DOBBIN.	KEPLER.....	ROY. E. B. KIRK.
HYDROPHOBIA.....	M. PASTEUR & Prof. J. A. THOMSON.	KHIVA; KANDAHAR.....	Professor ARMINIUS VAMBÉRY
HYGIENE.....	Dr ANDREW WILSON.	KINGSLEY.....	ULRICH BURKE.
HYMN.....	REV. JOHN JULIAN.	KNOX.....	P. HUMF MILNE, LL.D.
HYPNOTISM.....	Dr R. W. FELKIN.	KORAN.....	REV. JOHN MILNE.
IBSEN; LESSING.....	J. T. BEALEY.	KUFIC COINS.....	STANLEY LANE-POOLE.
ICELAND.....	JÓN A. HJALTALF.	LACE; LEATHER.....	JAMES PATON.
IDAH0; INDIAN TER.....	JACQUES W. REDWAY.	LAFONTAINE.....	WALTER HWYTE.
IGNEOUS ROCKS, &c.....	Professor JAMES GEIKIE.	LAKE-DWELLINGS.....	JOSEPH ANDERSON, LL.D.
ILLEGITIMACY.....	BENJAMIN TAYLOR.	LAMB, CHARLES.....	CHRIS ANSER.
ILLINOIS.....	ColoRD H. G. REEVES.	LAMPS.....	WILLIAM LOVEL.
ILLUMINATION; INDEX.....	HENRY B. WHITLEY.	LANCASHIRE.....	C. FAIRBAIRN.
ILLUSTRATION.....	J. R. PAIRMAN.	LAND LAWS.....	J. BOYD-KINSLAR.
IMMIGRATION.....	ARNOLD WHITE.	LAÓ-TSZE.....	Professor LEBGE.
INDEPENDENTS.....	REV. W. COOKE RUSSELL.	LASSALLE.....	THOMAS KIRKUP.
INDIA.....	SIR R. HARDY TEMPLE, G.C.S.I., D.C.L.	LATIN; LUCRETIVS.....	REV. W. J. PROMBIER
INDIANA.....	GEORGE J. LANGDALE.	LEAF.....	Professor PATRICK GEEDER.
INDIAN OCEAN.....	SIR JOHN MURRAY.	LEE, GENERAL.....	N. B. WEBSTER.
INDIA-RUBBER.....	JOHN A. CLAUDE.	LEDS.....	J. FENWICK.
INK.....	ROBERT IRVINE.	LEIGHTON; LETTERS.....	THOMAS DAVIDSON.
INSANITY.....	Dr F. S. CLOUSTON.	LEIPZIG.....	FINDLAY McHEAD.
INSCRIPTIONS.....	CHAS. ISAAC TAYLOR.	LEONARDO DA VINCI.....	J. M. GRAY.
INSECTS & I. PLANTS.....	Professor J. A. THOMSON.	LE SAGE; LORENTE.....	JOHN ORMSBY.
INSURANCE.....	GEORGE KING, F.S.A.	LEYDEN, JOHN.....	ROBERT COCHRANE.
INTERNATIONAL LAW.....	JAMES M. IRVINE.	LIBEL.....	FRANCIS WATT.
IOWA.....	F. W. HORSFIELD.	LIBRARY.....	T. G. LAW, LL. D.
IRELAND.....	JUSTIN MCCARTHY, M.P.; Prof. MAC- KINNON; Prof. G. T. STOKES, D.D.	LIFEROAT.....	C. DIBBIN (See Lifeboat Inst.).
IRON.....	W. MATHER WILLIAMS.	LIGHT; LENSES.....	Dr ALFRED DANIELL.
IRVING, WASHINGTON.....	F. H. UNDERWOOD, LL.D.	LIGHTHOUSE.....	D. & T. STEVENSON.
ISAIAH.....	Prof. GEORGE ALAN SMITH.	LIGHTNING.....	R. T. OMOND.
ISLAND; LATITUDE.....	HUGH ROBERT MILL, D.Sc.	LINCOLN, ABRAHAM.....	Professor J. P. LAMBERTON.
ISOCRATES; ISLEUS.....	F. B. JEVONS.	LION; LEOPARD.....	F. E. BEDDARD, F.R.S.
ITALY (Geog. & Hist.).	W. DEWDAS WALKER.	LIQUOR LAWS.....	SIR CHARLES WENTWORTH DOBIE.
(Literature).....	SIGNOR CANTAGALLI.	LINTE.....	COLIN SIALKER.
JACKSON, ANDREW.....	Professor J. P. LAMBERTON.	LITHOGRAPHY.....	J. R. PAIRMAN.
JAMES I.....	JOHN RUSSELL.	LIURGY; LITANY.....	MARQUIS OF BULL.
JAPAN.....	Professor DIXON (Tokyo).	LIVER.....	Professor HAYGARTH and Dr LUNDIE.
JAVA.....	E. METZGER.	LIVERPOOL.....	THOMAS EDISON.
JEFFERSON, THOMAS.....	Professor N. B. WEBSTER.	LIVINGSTONE.....	Professor W. G. BLAIRIE, D.D.
JERROLD, DOUGLAS.....	WALTER JERROLD.	LLOYDS.....	Col. HENRY MONTAGUE HOZIER.
JERUSALEM.....	SIR WALTER BESANT.	LOCKE.....	Professor A. CAMPBELL FRASER.
JEST-BOOKS; JESTERS.....	W. A. CLOUTON.	LOGIC; LOTZE.....	Professor FRINGLI-PATTON.
JESUS CHRIST.....	DEAD PAUPER.	LONDON.....	REV. W. J. LOTTIE.
JEW.....	EM. DEUTSCH and ISIDORE HARBEL.	LONDON UNIVERSITY.....	T. E. M. DOUSE.
JOAN OF ARC; JULIAN.....	THOMAS DAVIDSON.	LONGFELLOW; LOWELL.....	F. H. UNDERWOOD, LL.D.
JOB.....	REV. PROFESSOR A. B. DAVIDSON.	LOUISIANA.....	JOSEPH A. BRAXN.
JOHN'S GOSPEL.....	REV. J. SUTHERLAND BLACK.	LUTHER.....	Principal THOMSON.
JOHNSON, ANDREW.....	Hon. FREDERICK W. SEWARD.	LYLY, JOHN.....	A. B. BULLER.
JOHNSON, SAMUEL.....	Professor HALES.	LYLTON, BULWER.....	F. HINDS GROOMIE.
JENIS.....	W. FRASER RAE.	MACAULAY.....	WILLIAM WALLACE.
JURY; LAW.....	THOMAS RALEIGH.	MACHIAVELLI.....	SIGNOR CANTAGALLI.
JUSTICE OF PEACE.....	A. WOOD RINDON.	MACHINE GUN.....	Lieut. Col. H. D. B. DUNTON.
JUSTINIAN.....	Professor HENRY GURDY.	MADAGASCAR.....	REV. JAMES STRIBBLE.
JUTE; LEAD; LINEN.....	ALEXANDER GALLILLY.	MADRAS.....	Professor MICHEE SMITH.
JUVENAL; LUCAN.....	Dr J. P. STOLLER.	MAGNETISM.....	Dr ALFRED DANIELL.
KANSAS.....	NOBLE F. FRENCH.	TERRESTRIAL.....	Professor CARROLL G. KNOTT.
KANT.....	JAMES H. JOHNSON SHILLING, LL.D.	MAINE.....	Dr CHARLES W. GREENIE.
		MALAYS.....	Professor A. H. KEANE.

The Publishers beg to tender their thanks, for revising the article 'Thomas à Kempis,' to the Rev. S. KETTLEWELL; for 'Kindergarten,' to HERK K. FROEBEL; for 'Immaculate Conception,' 'Indulgence,' 'Infallibility,' 'Inquisition,' to His Eminence CARDINAL MANNING; for 'Iona,' to the DUKE of ABERNETHY; for 'Edward Irving,' to Mrs OLIPHANT; for 'Italy,' to Signor LUIGI BODIO, Director-general of Italian Statistics; for 'Jamaica,' to Chief-justice CHILD, St. Lucia; for 'Journ,' to the Very Rev. the GENERAL of the Order; for 'Leighton,' to the Rev. Dr Blair of Durham; as also to the Very Rev. the Deans of Lichfield and Lincoln, to Professor HUXLEY and to the town-clerks of Inverness, Leicester, Macclesfield, and other towns.

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

H

Humber. the estuary of the rivers Ouse and Trent (and so of the Dove, Derwent, Wharfe, &c.), runs east and then south-east for a length of 38 miles, separating the counties of York and Lincoln, with a breadth varying from 1 to 7 miles. Its drainage basin, with an area of 9770 miles, is the largest in England; and by means of navigable streams and canals the Humber is connected across England with the Mersey, the Severn, and the Thames. The navigation is obstructed, especially on the north side, by banks and shoals. The Humber was the southern boundary of the ancient kingdom of Northumbria in the wider sense, and of Deira when Northumbria was divided into Bernicia and Deira; Mercia lay south of the estuary. By way of the Humber Danes and Northmen made many terrible incursions into England, notably in 867, 1013, 1066, and 1069. The great port on the Humber was anciently Ravenspur or Ravenspur, just inside Spurn Head. The process of erosion by the sea was already at work when Henry Bolingbroke landed here in 1399; soon after the place was wholly covered by the encroaching waters, and Hull became the port on the north shore, as Grimsby now is on the south. See *The Rivers of England* (Cassell, 1889), and *Boyle's Lost Towns of the Humber* (1889).

Humbert. See ITALY.

Humble-bee. See BEE.

Humboldt. a river of Nevada, rises in the NE. part of the state, and flows WSW. to Humboldt Sink, a lake over 40 miles in circumference, which has no outlet. Length, nearly 350 miles. The river, which is unnavigable even for canoes, is strongly impregnated with alkaline matter. The region through which it flows is barren, and the banks are destitute of trees or shrubs. The Central Pacific Railroad runs through the valley of the Humboldt.

Humboldt. FRIEDRICH HEINRICH ALEXANDER, BARON VON, one of the greatest of naturalists, was born at Berlin, 14th September 1769. His father, whom he lost when he was not quite ten years of age, was chamberlain to the king of Prussia. He studied at the universities of Frankfurt-on-the-Oder, Berlin, and Göttingen; and during his residence at Göttingen (1789-90) he made those visits of scientific exploration, the fruit of which was his first independent work, a treatise on the basalts of the Rhine. In the spring and summer of 1790 he made a tour through Belgium, Holland, England, and France. In June 1791 he entered the Mining Academy at Freiberg, where he enjoyed the instructions of Werner. His eight months' residence here led to the publication of his *Flora Subterranea Freibergensis* (1793). He was afterwards appointed to an office in the mining department, and spent some years in this capacity, chiefly at the Fichtelgebirge, in Upper Franconia. His researches here resulted in a work on the irritability of the muscular and nervous fibres of animals (1799). The desire of visiting tropical countries, however, led him to resign his office, and devote himself entirely to the study of nature. He spent three months at Jena, where he was the intimate associate of Goethe and Schiller. At Paris he contracted a friendship with Aimé Bonpland, afterwards his companion in many and various scenes. Some time after he obtained permission from the Spanish government to visit all the Spanish settlements in America and the Indian Ocean. He sailed from Corunna along with Bonpland on 5th June 1799. They visited Teneriffe, ascended the Peak, and made many scientific observations. On 16th July they arrived at Cumana in South America, and in the course of five years explored a vast extent of territory in what are now Venezuela, Colombia, Ecuador, and Peru, as well as in Mexico, which they crossed from west to east. In Havana Humboldt prepared materials afterwards employed in his *Essai Politique sur l'Isle de Cuba* (1826). At Paris he occupied himself in the

arrangement of his collections and manuscripts, and jointly with Gay-Lussac made experiments on the chemical constitution of the atmosphere. Having visited Italy, and returned to Berlin, he accompanied Prince Wilhelm of Prussia in 1807 on a political mission to France, and obtained leave from the government of his own country to remain there for the publication of his travels, for which the disturbed state of Germany at that time did not allow proper opportunity. He continued to reside in Paris till 1827. The wish of the king that he should reside in his native country was gratified in 1827, when he proceeded to Berlin, and there, in the winter of 1827-28, he gave lectures on the *Cosmos*, or physical universe.

In 1829 Humboldt again became a traveller, the Emperor Nicholas then sending out a well-appointed expedition to the north of Asia, to explore the Ural and Altai Mountains, Chinese Dzungaria, and the Caspian Sea. In this expedition Humboldt was accompanied by his two friends Ehrenberg and Rose. Its principal results were the scientific examination of the beds which produce gold and platinum, the discovery of diamonds in an extratropical region, the astronomical determination of positions, magnetic observations, and geological and botanical collections. The whole journey occupied nine months, and extended to 2320 miles, and is described in a work by Rose (2 vols. 1837-42) and in Humboldt's *Asie Centrale* (3 vols. 1843). The political changes of the year 1830 led to Humboldt's employment in political services; he was chosen by the king of Prussia to carry to Paris his recognition of Louis-Philippe, and during the ensuing twelve years was frequently sent to Paris to reside for four or five months. He accompanied the king of Prussia also in visits to England, Denmark, &c. During this time he published his *Essai Critique de la Géographie du Nouveau Continent* (5 vols. 1835-38). Humboldt spent the later years of his long life at Berlin, where he occupied a high position at the Prussian court. His last great work, *Cosmos* (4 vols. 1845-58), has been unanimously recognised as one of the greatest scientific works ever published, exhibiting in most lucid arrangement many of the principal facts of the physical sciences and their relations to each other. The style, however, is somewhat heavy, and, seen from our present standpoint, the author's views are in many respects defective. The germ of the work was the author's lectures in Berlin in 1828, themselves partially based on his *Ausichten der Natur* (1808). Humboldt died in his ninetieth year, May 6, 1859.

It is not easy to estimate the amount of Humboldt's contributions to science. The geography of Spanish-America was most imperfectly known previous to his travels there, during which he astronomically determined more than 700 positions, and he bestowed much labour on the preparation of the maps in which his discoveries were exhibited. His barometrical observations were likewise very numerous, as well as his observations on all points connected with meteorology. To him we are indebted for the most important generalisations concerning magnetism and also climate. He obtained distinction also by his labours in the determination of the magnetic equator, and by his observations on electrical eels, and on the respiration of fishes and young crocodiles. The editing and preparing of the great work of the American journey occupied twenty years of his life; and in his work he had the assistance of many of the most eminent scientists of the time Cuvier, Latreille, Gay-Lussac, Thenard, &c.—as well as the most distinguished artists and engravers. There is but one complete edition of the *opus magnum* (1807-17), in 30 vols. (20 folio and 10 quarto); the so-called small

edition being but excerpts. The title of the whole is *Voyages aux Régions Équinoxiales du Nouveau Continent, fait en 1799-1804 par Alexandre de Humboldt et Aimé Bonpland, rédigé par Alexandre de Humboldt*; and it falls into six sections, some of which and their parts are quoted as separate works (*Relation Historique, Observations de Zoologie, Observations Astronomiques, Physique générale et Géologie, Plantes Equinoxiales*, with atlases, essays, &c.). Humboldt is unquestionably one of the great figures of the century, and in private life was remarkable for benevolence and kindness, while his most conspicuous defect was vanity.

See the great biographical work, edited by Bruhns, *Alexander von Humboldt: eine wissenschaftliche Biographie* (1872; Eng. trans. 1873); and Lord Houghton's *Monographs* (1873). His correspondence with many of the most eminent men of the time has been published in many separate works—thus, that with Varnhagen (1800), with Von Raumer (1869), with Goethe (1876), with Campe (1877), with his brother Wilhelm (1880).

Humboldt, KARL WILHELM VON, the elder brother of the preceding, eminent as a statesman and for his works on philology, aesthetics, and general literature, was born at Potsdam, 22d June 1767, and educated at Berlin, Frankfurt-on-the-Oder, and Göttingen. He eagerly studied antiquities, aesthetics, and the Kantian philosophy, as well as law, to which he professedly devoted himself. After travelling in Germany, France, and Switzerland, he acquired the rank of counsellor of legation, but showed little inclination for official employment. In 1791 he married, and for some years resided chiefly on his wife's estate in Thuringia, and afterwards in Jena, associating most intimately with Schiller, and devoting himself to poetry and other literary and scientific pursuits. A valuable memorial of his friendship with Schiller is the correspondence between them. From 1797 to 1799 Humboldt resided partly in Paris and partly in Spain, and in 1801 became Prussian resident at Rome, where he remained for a number of years in this capacity, and in that of minister-plenipotentiary, a most generous patron of young artists and men of science. From Rome he returned to his native country to fill the high place of first minister of Public Instruction. The Berlin university owed its existence to him. In 1810 he went to Vienna as minister-plenipotentiary, and from this time he took part in all the most important political affairs in which his country was concerned. After 1819 he resided chiefly at Tegel, where he laid out fine pleasure-grounds, and formed a noble collection of sculptures by the greatest masters. He died 8th April 1835.

His earliest literary works were collected by himself under the title of 'Æsthetic Essays' (*Æsthetische Versuche*, 1799). His 'Collected Works' appeared in 7 vols. (1841-52). Humboldt devoted himself with the greatest assiduity to the study of philology, and was the first to make the study of the Basque tongue a scientific pursuit. He also spent much labour on the languages of the East, various questions connected with oriental literature, and the languages of the South Sea Islands. One of his most important works is on the Kawi language in Java (3 vols. 1836-40), published after his death by Edward Buschmann: the introduction to this, On the Variety of Structure in Human Speech, and his reflections on the influence thereof on the intellectual progress of mankind, mark a new era in the science of philology. *Letters to a Female Friend* (1847; Eng. trans. 1849) exhibit his character in a most pure and amiable light. See the admirable biography by Haym (1856), and his correspondence with Schiller (1830; new ed. 1876), Goethe (1876), Körner (1879), and his brother Alexander (1880).

Hume, DAVID, philosopher and historian, was born at Edinburgh on the 26th of April 1711 (o.s.). His father was the laird or proprietor of the estate of Ninewells, in Berwickshire, but David, being the younger son, had to make his own fortune with no other assistance than an education and the influence of his respectable family. He was educated at home and at the university of Edinburgh. His father designed law as his profession, and he submitted to the initial steps of the proper practical training, but it was not a pursuit to his liking. Deserting it, he made experiment of a mercantile life in Bristol; but commerce was not more congenial to him than jurisprudence, and he gave it a very short trial. He now became a student, devoting himself to books with no settled practical object before him. He has recorded his sufferings at this time from despondency and depression of spirits, caused apparently by the effects of monotonous study. At twenty-three years of age he went to France and lived some time in La Fleche, where he describes himself as wandering about in solitude, and dreaming the dream of his philosophy. In 1739 he published the first and second book of his *Treatise on Human Nature*—the germ of his philosophy, and still perhaps the best exposition of it, since it has there a freshness and decision approaching to paradox, much modified in his later works. Although the dawn of a new era in philosophy, this book was little noticed; in his own words, 'it fell dead-born from the press.' It was a work of demolition. By separating the impressions or ideas created on the thinking mind by an external world from the absolute existence of that world itself he showed that almost everything concerning the latter was taken for granted, and he demanded proof of its existence of a kind not yet afforded. It was thus that he set a whole army of philosophers at work, either to refute what he had said, or seriously to fill up the blanks which he discovered: thus he gave the original impulse both to the Scottish school of philosophy—Reid, and the rest—and to Kant's speculations. In 1741 and 1742 he published two small volumes called *Essays Moral and Political*; they were marked by learning and thought, and elegantly written, but are not among the more remarkable of his works.

He felt keenly at this time the want of some fixed lucrative pursuit, and his longing for independence was the cause of a sad interruption to his studious and philosophical pursuits. He was induced to become the companion or guardian of an insane nobleman, and had to mix with the jealousies and mercenary objects of those who naturally gather round such a centre. In 1747 he obtained a rather more congenial appointment as secretary to General St Clair, whom he accompanied in the expedition to the coast of France and the attack on Port L'Orient, the depot of the French East India Company; this affair had no important results, but it gave Hume a notion of actual warfare. Next year he accompanied the general in a diplomatic mission to France, and as he travelled he took notes of his impressions of Holland, Germany, and Italy, which are published in his *Life and Correspondence*.

In 1751 he published his *Impugnatio into the Principles of Morals*, a work of great originality, and one of the clearest expositions of the leading principles of what is termed the utilitarian system. At the same time he intended to publish his *Dialogues concerning Natural Religion*; but his friends, alarmed by the sceptical spirit pervading them, prevailed on him to lay them aside, and they were not made public until after his death. In his thirty-fifth year he had unsuccessfully competed for the chair of Moral Philosophy in Edinburgh, and at this period we find him unsuccessful in an attempt to obtain the chair of Logic in Glasgow.

Next year, in 1752, appeared his *Political Discourses*. Here, again, he made an era in literature, for in this little work he announced those principles of political economy, comprehending the doctrine of free trade, which it fell to his friend Adam Smith more fully and comprehensively to develop. He was appointed at this time keeper of the Advocates' Library, with a very small salary, which he devoted to a charitable purpose. It was here that, surrounded with books, he formed the design of writing the history of England. In 1754 he issued a quarto volume of the *History of the Stuarts, containing the Reigns of James I. and Charles I.*, and presently completed this portion of the work in a second volume, bringing it down to the Revolution. The second volume attracted more notice than the first had done. He then went backwards through the House of Tudor, and completed the work from the Roman period downwards in 1762. While so employed he published *Four Dissertations: of the Natural History of Religion; of the Passions; of Tragedy; of the Standard of Taste* (1757). Two other dissertations, intended to accompany these, were cancelled by him after they were printed—they are *On Suicide* and *The Immortality of the Soul*, and were subsequently printed in his works.

In 1763 he went to France as secretary to Lord Hertford's embassy; here he was in his element, and found fame at last. He became familiar with the brilliant wits and savants of the Parisian circle—with Turgot, D'Alembert, Helvetius, Holbach, Diderot, Buffon, Malesherbes, Crébillon, and the rest, as well as with the hardly less distinguished women, De Bonniers, Du Deffand, and L'Espinasse. His sojourn in Paris was unfortunate in bringing him into intimacy with the restless, vain, and self-tormenting Rousseau, who, after experiencing much substantial kindness from Hume, got suspicious, and forced him into a memorable quarrel. After his return home, in 1766, he accepted the responsible office of Under-secretary of State for the Home Department. In his own Life he says: 'I returned to Edinburgh in 1769 very opulent (for I possessed a revenue of £1000 a year), healthy, and, though somewhat stricken in years, with the prospect of enjoying long my ease, and of seeing the increase of my reputation.' His health gave way in 1774, and he died at Edinburgh, 25th August 1776.

Hume is the outcome of the empirical philosophy of Locke. His philosophical writings do not form a system, but discuss many of the salient ideas of philosophy, mainly in a sceptical or destructive manner. Ideas are but weakened copies of 'impressions' of the senses, outer or inner; mind is a succession of isolated impressions and ideas; the idea of cause depends on the habit of mind which expects the event that usually follows on another, and there is no necessary connection between cause and effect. Hume's History, which gives him a high rank among English historical authors, was not remarkable for historic impartiality (in a later edition more than a hundred alterations on the reigns of the first two Stuarts were made by Hume himself, and all to the Tory side), and has been largely superseded by more modern works; but new editions, with or without the continuation by Smollett, still appear; Dr Brewer's *Student's Hume* (1858) being a recognised text-book. Hume's position in relation to his predecessors and successors is given under BERKELEY; the article CAUSALITY is largely concerned with the discussion of his views. For the influence of Hume's scepticism in awaking Kant from his dogmatic slumber, see KANT. The most important edition of Hume's works is that by T. H. Green and T. H. Grose (4 vols. 1874), with introduction and exhaustive analysis of Hume's philosophy. *The Life and Correspondence of David Hume* was published by J. Hill Burton (2 vols. 1846); Dr G. Birkbeck Hill edited *Letters of David Hume to William Strathairn*, with copious and valuable notes, in 1889. For his theological position, and his relation to Edinburgh society, comprehended by his 'infidelity,'

see Leslie Stephen's *English Thought in the Eighteenth Century* (1876), the autobiography of 'Jupiter' Carlyle, &c. There are short monographs by Prof. Huxley ('English Men of Letters' series, 1879), Prof. Knight ('Philosophical Classics' series, 1886), and Prof. Calderwood ('Famous Scots' series, 1898); and German works by Jodl (1872), E. Pfeleiderer (1874), and Gizeycki (1878).

Hume, JOSEPH, politician, was born 22d January 1777, at Montrose. He studied medicine at Edinburgh, and in 1797 became assistant-surgeon in the service of the East India Company. He applied himself to the acquisition of the native languages, and during the Maharratta war, from 1802 to 1807, filled some half-dozen important offices, chief amongst which were those of interpreter and commissary-general. On the conclusion of peace he returned to England in 1808, his fortune made. Becoming imbued with the political philosophy of James Mill and Bentham, he gained admission to parliament, sitting as member for Weymouth, Aberdeen, Middlesex, Kilkenny, and Montrose successively, this last from 1842 to his death, which occurred on 20th February 1855. 'An uncompromising honesty, an instinctive hatred of abuses, an innate love of liberty, and an unflinching will to extend its benefits to others—these, and the close experience of men derived by himself during the earlier part of his life, rendered Mr Hume one of the most powerful, and at the same time one of the most practical, of reformers in a reforming age. Amongst the schemes and reforms he advocated may be enumerated the establishment of savings-banks, freedom of trade with India, abolition of flogging in the army, of naval impressment, and of imprisonment for debt, repeal of the act prohibiting export of machinery, and of that preventing workmen from going abroad, reduction of election expenses, abrogation of duties on paper, and removal of abuses of all and sundry kinds whatsoever. He was also chief agent in discovering the treasonable designs of the Orange lodges, which proposed to make the Duke of Cumberland king on the decease of William IV.

Hume, PATRICK (1641–1724), an eminent statesman and covenanter, Lord Chancellor of Scotland, who in 1690 was created Lord Polwarth, and in 1697 Earl of Marchmont. See BAILLIE (LADY GRIZEL).

Humeral, an oblong scarf worn by priests and subdeacons round their shoulders at certain parts of the service of the Mass and of Benediction, the paten, pyx, or monstrance being also wrapped in it (so as to prevent contact at those times with naked hands).

Hummel, JOHANN NEPOMUK, pianist and musical composer, was born at Presburg, 14th November 1778. He first studied under Mozart, and then, after a seven years' concert tour in Germany, Denmark, England, and Holland, he returned to Vienna to complete his musical education under Albrechtsberger and Salieri. From 1803 to 1811 he held the post of musical director to Prince Esterhazy; and in 1816 he filled a similar position at Stuttgart, but moved four years later to Weimar, where he died, October 17, 1837. In the course of several musical tours he delighted the capitals of Europe with his pianoforte playing and his clever improvisations on that instrument. Of his musical compositions the only ones which have value at the present day are his pianoforte works.

Humming-bird (*Trochilus*), a Linnæan genus of birds, now constituting a family, Trochilidae. The nearest relations of the humming-birds are the Swifts (q.v.); that they form together with the swift one large group is clear from their very close resemblances in anatomical structure. Nitzsch, Huxley, Gariod, and others who have investigated

the osteology, muscular anatomy, and other points concur in this opinion as to the relationship of the family; they resemble in their habit and in brilliancy of plumage the Sun-birds (q.v.), which replace them in the eastern tropical regions. The dazzling brilliancy of humming-birds, the extreme rapidity with which they dart through the air, their hovering above the flowers from which they obtain their food, with humming sound of wings, which move so quickly as to be indistinctly visible, or 'like a mist,' have attracted universal admiration since the first discovery of America. The diminutive size of almost all of them—some of them being the smallest of birds, and if stripped of their feathers not larger than a humble-bee—has still further contributed to render them objects of interest, whilst the plumage of the different species exhibits an almost endless variety of colours. Some species possess 'the most gorgeously brilliant metallic hues known among created things:' some on the other hand are sombre

a, Sword-bill Humming-bird (*Docnaustes cusifer*);
b, White-booted Racket-tail (*Steganurus Underwoodi*);
c, c', male and female Tufted Coquette (*Lophornis ornatu*).

in hue. Humming-birds are entirely confined to the American continent and West Indies, where there are about 120 genera, containing over 400 species; no less than 15 species occur in North America. Of the South American forms the majority inhabit the hotter regions, but some are confined to elevated mountain-tracts even above the snow-line.

Humming-birds have slender bills, which are also generally long, and in some extremely so, the form of the bill exhibiting a wonderful adaptation to the kind of flowers from which the bird obtains its food—straight in some, curved in others. Humming-birds do not, as was long supposed, feed on honey alone, but to a considerable extent, and some of them perhaps chiefly, on insects, not rejecting spiders, whilst they often snatch away the insects which have become entangled in spiders' webs. The tongue is very long, capable of being darted out to a considerable length; the bone of the tongue (hyoid bone) being much elongated, and its branches passing round the back of the skull to the forehead, where they meet in a point before the line of the eyes. The tongue itself consists of two hollow filaments, joined together for the greater part of their length, and separated at the tip; the structure of the tongue and hyoid bones is curiously like that of the Woodpeckers (q.v.) and the sun-birds already referred to; this affords an illustration of the fact that similar requirements often cause

development of similar structures in animals otherwise distinct. The wings of humming-birds are very long and powerful, like those of the swifts, the length being particularly marked in that portion of the wing which corresponds to the hand of mammals; hence the name *Macrochires* which is applied to the group. Humming-birds construct their nests with nice art, generally of lichens and of fibrous substances, such as cotton. They do not lay more than two eggs. They are very bold in defence of their nests and young, and are said to strike fearlessly with their needle-like bills at the eyes of birds of prey, which they far surpass in agility and rapidity of flight. They are very easily tamed and rendered familiar, and have been known to return again in spring, after a winter migration to a warmer climate, to the window from which they had been allowed to escape. Attempts to keep tamed humming-birds have generally failed; and they have almost never been brought safely across the Atlantic. Humming-bird skins were anciently used by the Mexicans for making pictures.

See John Gould's magnificent *Monograph on the Trochilidae* (5 vols. 1849). Gould's collection of specimens was bought for the British Museum.

Humperdinck. ENGELBERT, composer, was born at Siegburg, near Bonn, 1st September 1854; and after studying music at Cologne, Frankfort, Munich, &c., and travels in France, Spain, and Italy, taught in the conservatoriums of Barcelona and Cologne, and was musical adviser to a publishing firm in Mainz. Wagner summoned him to assist in the production of that master's only symphony; and it was he who prepared and coached the first cast of *Parsifal* at Baireuth (1882). He subsequently settled in Frankfort (1890), and became famous as the author of the phenomenally successful children's opera or musical fairy play, *Hansel and Gretel* (1894), which was followed by *Schneewittchen* ('The Snow Maiden') and *The Royal Children*.

Hunchback. See SPINAL COLUMN.

Hundred. In English law, an ancient subdivision of counties, the name of which probably arose from there being a hundred warriors, or perhaps a hundred families, or ten tithings, in each (see FETTERALISM). In ancient times, if a crime was committed, such as robbery, maiming of cattle, burning of stacks, &c., the hundred had to make it good. The old distinctions have, however, now less significance. But the characteristic of a hundred is still this, that it has a constable or bailiff, and when any damage is done by rioters feloniously destroying property the owner has his remedy by suing the hundred for the damage. In order to secure this remedy the party or his servant must, within seven days, go before a justice, and engage to prosecute the offenders, when apprehended. So, where there is no hundred, the county, or city, or town is liable in like manner. Execution is levied on the treasurer of the county. In the northern counties a hundred was called a wapentake (Yorkshire) or a ward. See RIOT, COUNTY.—The townships in Delaware, U.S., are also called Hundreds. See Professor G. E. Howard's *Introduction to the Local Constitutional History of the U.S.* (Baltimore, 1889).

The Hundred Days is a name often given to the period between Napoleon's landing in France after his escape from Elba (1st March 1815) and the battle of Waterloo (18th June 1815). See FRANCE, NAPOLEON I.

Hungary (Hung. *Magyarország*, Ger. *Ungarn*, Lat. *Hungaria*) is the eastern and larger half of

the Austro-Hungarian monarchy, covering an area of about 125,000 sq. m., between 44° 10' and 49° 35' N. lat., and between 14° 25' and 26° 25' E. long. Comprising Hungary proper, Transylvania, Croatia and Slavonia (nominally also Dalmatia), and Fiume, it forms the realm of the crown of St Stephen or Transleithania, which is a coequal factor with Austria or Cisleithania in the empire-kingdom ruled over by the Hapsburg dynasty. The two states form a union under one monarch for military, diplomatic, and customs purposes, but otherwise retain their distinct independence of each other. The form of its government as well as its geographical, industrial, and statistical features having been dealt with in the article AUSTRIA, it now remains only to give an account of the history, language, and literature of the country, or its chief and ruling inhabitants, the Magyars.

History.—But little is known of the history of the Hungarians previous to their appearance in Europe in 884. They are generally believed to be the descendants of the Scythians, and to have come from regions about the Caspian Sea. They first settled along the Middle Volga, but, having been pressed westwards, they in 889 crossed the Carpathian Mountains under Almos, and under the further leadership of his son Arpad they conquered the ancient Pannonia and Dacia of the Romans; and this, their new country, was in the year 1000 formed into a regular kingdom by Stephen. For his merits in Christianising his people Stephen was afterwards created a saint, and received from Pope Sylvester II. the title of 'apostolic king' and a crown, both of which have been worn by all the kings of Hungary to the present day. The Hungarians were at first an extremely warlike and even savage tribe; and, not content with subduing the various nationalities inhabiting the ancient Roman provinces, they made frequent expeditions into Germany and Italy, destroying the early results of Christian civilisation. All this, however, ceased on, and even before, the accession of Stephen, who turned his attention solely to the consolidation of Christianity and interior order and prosperity. He laid the foundation of many institutions surviving to the present day, such as the ecclesiastical organisation, the archbishoprics and bishoprics, the municipal and county councils, and even the national council, which eventually developed into the Diet of the States. Within two decades after his death (1038) two attempts were made to overthrow Christianity, and to re-establish Paganism, but only with very slight and temporary success. Under Bela I. (1061-63), Ladislaus the Saint (1077-95), and Coloman the Learned (1095-1114), the country made very marked progress. The reign of Andrew II. is remarkable on account of the nobles having extorted from him in 1222 the 'Golden Bull,' or Hungarian Magna Charta, the privileges of which were in 1231 extended to the clergy and lower nobility. The 'Golden Bull' conferred many personal and material advantages on the nobles, and also contained a guarantee for the annual convocation of the diet; it conceded the right of armed resistance to any illegal acts of the king. During the reign of Bela IV. (1235-70) Hungary was devastated by a terrible Mongol invasion. To replace part of the population cruelly massacred by the Asiatic savages, Bela introduced German colonists; hence the German-speaking communities in Hungary to the present day. By the death of Andrew III. in 1301 the House of Arpad became extinct, and the throne of Hungary became an object of rivalry between various foreign potentates. After many vicissitudes, Hungary was fortunate enough to find a worthy king in the person of Charles Robert of Anjou (1308-42),

who did much to place his adopted country on a level with more civilised western nations. His son, Louis the Great, made Hungary the most powerful nation of the period in central Europe. After the death of Ladislaus Posthumus (1457), Matthias Corvinus, the son of Hunyady, the great anti-Turkish hero and regent during that king's minority, was elected king. Under his reign Hungary attained to the pinnacle of fame, prosperity, civilisation, and power. He waged successful wars against Podiebrad of Bohemia, and got himself crowned king of Bohemia and Moravia. He also defeated the Turks at Kenyérmező, and reconquered the southern provinces held by them. In 1485 he even took Vienna and made it the capital of his country, which was at that time more extended than ever before or after. But Matthias was not only a great general; he was also a great legislator, a munificent patron of art and sciences, and a great judge. His impartiality and love for the people were so generally recognised that to the present day there lives in Hungary the proverb: 'King Matthias is dead; there is no more justice.' Matthias having died without legitimate heirs, the throne of Hungary again became the object of fierce struggles between various pretenders, and the country underwent in consequence a period of rapid decay. Under Vladislaus (1490-1516) Hungary was the scene of a sanguinary peasant insurrection, known as the *Dozsa* revolt, which was ultimately suppressed, and led to a system of abject serfdom. Louis II.'s reign was still more disastrous. The Turks, under Soliman the Great, took advantage of the enfeebled condition of the country, invaded it with a gigantic army, annihilated the Hungarian forces at Mohács, pillaged whole districts, including Buda with the world-famous *Bibliotheca Corvina*, and carried off some 30,000 Hungarians as slaves. Louis II. himself lost his life in or after the battle of Mohács, and the Hungarian throne became once more the prize of contention between two claimants. One was John Zápolya, Voivode of Transylvania, whom one section of the nobles proclaimed king, the other was Ferdinand of Austria, brother-in-law of Louis II. Zápolya was supported by the Turks, Ferdinand by the majority of the Hungarian nobles. Eventually Zápolya surrendered his claims to the whole kingdom, merely retaining Transylvania and the Transylvanian district of Hungary for life. Thus the Hapsburgs obtained at length a final footing in Hungary, and the country entered on a period of endless suffering and humiliations.

The successors of Ferdinand—viz. Maximilian, Rudolph, Ferdinand II., Ferdinand III., and Leopold I.—when they were not engaged with the Turks, concentrated their energies on the suppression of Protestantism in Hungary. The Protestants won several victories over the Imperialists, as in 1604-6 under Stephen Bocskay, in 1620-21 under Bethlen Gabor, in 1644 under George Rákóczy, thus forcing the government to show more toleration towards the followers of the new religion; but the kings being under Jesuit influences, all treaties and promises were broken on the first opportunity. Especially ruinous was the long reign of Leopold I. (1657-1705), who, with the most merciless determination, used all means at his disposal, as he himself said, to 'impoverish, enslave, and recatholicise' Hungary. Some of his own highest office holders, although themselves Catholics, so much resented his terrible treatment of the Protestants that they began a conspiracy for the separation of Hungary from the Hapsburg dominions; but the plot having been detected, the ringleaders were put to death. For many years the scaffolds were at work in sus-

pected districts, and thousands of valiant families, mostly Protestants, were exterminated. A Protestant rising, under Count Emeric Toköly, and supported by Kara Mustapha, proved very successful in 1683, and very nearly led to the capture of Vienna and the utter destruction of Austria; but at the last moment John Sobieski, king of Poland, saved Vienna and the Hapsburgs. After the retreat of the Turks from Vienna they gradually lost their hold on Hungary.

Leopold died in 1705 amidst the anxieties entailed upon him by another Hungarian rising, led by a second Francis Rákóczy, which did not end before 1711. Leopold succeeded in causing the diet to declare the throne hereditary in the House of Hapsburg, and Charles VI. (1711-40) received their adhesion to the Pragmatic Sanction, securing the right of succession in the female line. Nevertheless, his daughter Maria Theresa's claim to the throne was called in question by several German rulers and by France, her dominions were invaded, and she saved them and herself only through the magnanimous self-sacrifice of the Hungarians. She was the first Hapsburg ruler who showed herself grateful to the Hungarians, and who proved herself to understand the duties of a sovereign. She made several concessions to the Protestants, improved the condition of the peasants, and established schools. Her son and successor, Joseph II. (1780-90), does not strictly figure among Hungarian kings, as he had never himself been crowned in Hungary, but carried on his reign in violation of the Hungarian constitution as an autocratic emperor. He was an enlightened reformer, but did not reckon with national feelings, class idiosyncrasies, interests, and prejudices; he attempted to make Hungary part of a vast pan-Germanic bureaucracy; and many of his measures fostered the discontent to such a degree that at his death he saw himself compelled to recall all his illegal edicts, with the exception of one—viz. that enjoining religious toleration. Leopold II. at once convoked the diet (the first for twenty-five years), and confirmed the rights and independence of the nation. His conciliatory reign lasted only two years, and he was succeeded by Francis I. (1792-1835), whose ambition it was to follow the example of his least reputable predecessors. As long as the Napoleonic wars lasted, and the Hungarians supported him with money and troops, he played at constitutionalism; but as soon as the Napoleonic dangers were passed he showed himself in his true character, discontinued the diets and levied troops and taxes at his pleasure till 1825, when he was driven by the general discontent and resistance to convolve the states.

This diet marked the beginning of the new era in Hungary. The nation commenced to awaken to the consciousness of its many wants, intellectual and material; the desire for reforms was fast ripening. The majority of the delegates to the next diet (1832) were already bearers of radical instructions. The desired reforms, however, were slow in coming, owing to the narrow-minded policy of Metternich and the whole court party. The diet of 1832 counted among its members such men as Count Louis Batthányi, Baron Nicholas Wesselényi, Baron Joseph Eötvös, Francis Deak, and Louis Kossuth. The more important reforms passed by this and the subsequent diets of 1839 and 1843 were those regarding the official use of the Hungarian language, the eligibility of non-nobles to public offices, and the equal rights of Christian denominations. Outside parliament there was no less activity than inside. Kossuth's *Pesti Hírlap* (the first Hungarian political daily paper), which in enthusiastic language taught the masses how to demand their rights, rapidly spread all over

the country. Kossuth advocated the abolition of serfdom, the equality of all citizens, the liability of nobles to taxation, and freedom of the press. He was returned to the diet of 1847 as senior member for the county of Pest, and it was on his motion that the House resolved in March 1848 to send a deputation to Vienna to demand all these and various other reforms. Ferdinand V., a weak-minded man, who had reigned since 1835, yielded after some hesitation, and the first Hungarian responsible ministry entrusted with the task of carrying the said measures was appointed. Count Louis Batthányi was prime-minister, Peak minister of justice, and Kossuth minister of finance. But the court party were secretly determined to frustrate all these reforms, which openly they did not dare to oppose. They therefore incited the Croats and other non-Hungarian nationalities to rise against Hungarian supremacy. Accordingly Croatia, Slavonia, the Serbian Banat, and eventually the Roumans of Transylvania took up arms against Hungarian rule; and when the central government in Vienna was appealed to it issued highly-worded proclamations against the rebels, but gave very scant help to subdue them, whilst secretly it supplied them with arms, ammunition, and money. The Hungarian government, so treacherously abandoned, proceeded to obtain from parliament the vote of a levy of 200,000 men and 42 million florins of money, but to these measures, unanimously decreed by parliament, the crown withheld its assent. Later on, September 6, when a deputation of 120 members waited on Ferdinand to urge him to oppose the Croatian invasion, the court again gave an evasive reply. But a few days later, having received good news respecting the army operating in Italy, the court threw aside the hypocritical mask hitherto worn, and declared open hostility to Hungary by ignoring the existing constitution and government, recalling the Palatine Archduke Stephen, and appointing Count Lamberg governor-general and royal commissioner for Hungary. Parliament declared these acts illegal, and Count Lamberg was murdered on his arrival by the enraged population of Budapest. The ministry now resigned, and a committee of national defence was appointed with Kossuth as president. A comparatively numerous army was rapidly equipped and sent to meet Jellachich, who was marching towards Budapest at the head of the Croats. He was completely beaten at Velencez, and during an armistice of three days, which was granted him by the victorious Hungarians, he fled ignominiously towards Vienna. Notwithstanding this defeat he was appointed commander-in-chief of all the forces and alter-ego of the emperor-king in Hungary; and all the decrees and resolutions of the Hungarian parliament were declared illegal.

On December 2 Ferdinand was compelled by a family council to abdicate in favour of his nephew, Francis-Joseph, who was then eighteen years of age. In his name the war began to be carried on bitterly against Hungary, all the more as the diet declared the succession unconstitutional. Up to the middle of January next fortune seemed to favour the Austrian arms: the Hungarians, though they fought valiantly and obtained some victories, had to retreat before the overwhelming numbers of the enemy; the whole trans-Danubian district and the north and south were lost to them; they had only the vast plains of the Alföld and Transylvania, where Bem entirely subdued the rebellious nationalities. Meanwhile the Russians were also coming to the aid of the Austrians, so that the Hungarians had fair reason to despair of their own position. It was only the inactivity of Windischgratz, the new Austrian generalissimo, that

saved the Hungarians. His aimless stay at Budapest gave Kossuth time to perambulate the country, and by his stirring eloquence and boundless energy to create a splendid though irregular army, which, under the various leadership of Dembinski, Vetter, Görgei, Klapka, and others, won so many victories over the Austrians within the next three months that by the end of April the country was almost entirely free from the enemy. The many defeats of the Austrian regular forces by the Hungarian irregulars so exasperated the Vienna court that, on March 4, 1849, it promulgated a decree abolishing the Hungarian constitution; to which the Hungarian diet replied by the declaration of independence, and the dethronement of the Hapsburg dynasty on April 14. No final form of government was decided upon, but Kossuth was temporarily elected governor-president, and instead of the committee of national defence a new ministry was formed under the presidency of Bartholomew Szemere. Had Görgei not disregarded Kossuth's advice, had he forced his way to Vienna after so many victories, the whole war might have come to an end with glorious results for Hungary; but Görgei decided to first retake Budapest, and thereby enabled the united Russian and Austrian armies to invade the country at various points. These combined armies consisted of no less than 275,000 men, with 600 batteries, whilst the Hungarians numbered barely 135,000, with no artillery to speak of. In these circumstances the Hungarians had little chance of defending themselves with any measure of success, but they continued to fight with the greatest determination. Fortune still smiled on them here and there, but on the whole chances and events were against them. This decline of their fortunes was aggravated by the serious dissensions between Görgei and Kossuth, which grew daily in intensity till the latter thought it advisable, in order not to hamper the other's strategic activity, to abdicate in favour of Görgei on August 11, 1849. Once in the possession of the chief political and military power, Görgei no longer thought of continuing the struggle, but immediately and unconditionally surrendered himself to the Russians. This act on his part was defended by him as one imposed by necessity and a saving of further bloodshed; but examined in the light of his former conduct and of the fact that he induced, by empty and futile promises for the safety of their persons and their troops, thirteen other generals to follow his example, it is generally considered by the majority of his countrymen an act of unpardonable treason. Kossuth and several other military and political leaders fled to Turkey, whilst the others who remained behind and were captured were either sentenced to long terms of imprisonment or shot and hanged like mere criminals. Among the latter were Count Louis Batthányi and the thirteen generals betrayed by Görgei, including Count Charles Leiningen, a relative of the Queen of England. Görgei himself was sent to Klagenfurt, and kept there on a small pension. Hungary was incorporated into and governed as an hereditary province of Austria, the governor being General Haynau, who wielded his official power with extraordinary harshness and cruelty. Political prisoners were tortured, women publicly flogged, properties and rights confiscated. With the exception of the abolition of serfdom all the acts of the diet of 1848 were annulled, and Hungary was governed by a host of foreign officials according to Austrian laws and institutions. The country displayed no active resistance, nevertheless all the efforts of this centralising and Germanising system so completely failed that by 1857 the Vienna government began to see its futility and to offer some concessions.

After the disastrous Italian war in 1859 the old Hungarian chancellery, as it existed previous to 1848, was re-established, but failed to satisfy the Hungarians, whose passive resistance threatened with a final breakdown the Austrian state machinery. At length in 1861 the diet was once more convoked; but, as it demanded the full restitution of the constitution of 1848, it was quickly dissolved. Gradually, however, better counsels prevailed at the court of Vienna. Parliament was again summoned in 1865, and the demands of the Hungarians, as formulated by Deak and his party, were complied with, and resulted in the agreement described in detail in the article AUSTRIA. Francis-Joseph was crowned king of Hungary, June 7, 1867, and entered on the faithful discharge of his duties as constitutional monarch. There is still a numerous party in Hungary in favour of complete separation from Austria, but none are hostile to the sovereign. The renewal of this decennial financial arrangement (1897-98) led to very strained relations between the two sections, the Hungarians declining to raise their contributions from 31·4 to 42 per cent. of the common expenditure. Hungary made good use of the period of internal peace enjoyed after the coronation, and made rapid strides in the path of civilisation. It established an admirable system of elementary and higher education, built a magnificent net of railways (now largely in the hands of the state), improved its judicature, developed commerce and industry, and organised, in addition to the Austro-Hungarian common army, an effective system of national defence, the Honvéds. Budapest, its capital, equalled by few, surpassed by none among the great cities of Europe, is watched with as much envy by the Austrians as the growing influence of the Hungarians in the common councils of the monarchy. Lately the former heavy deficits have disappeared from the budget, and there is every hope of the kingdom soon being in a condition to reduce its heavy debts. The various nationalities in Hungary (Servians, Wallachs, Ruthens, Slovaks, Germans) enjoy the same rights as the native Magyars, which are considerably greater than in Austria; there is therefore comparatively little discontent prevailing among them, even though panslavistic missionaries strive to make mischief. Much of Hungary's steady progress is due to the fact that since the new era there have been few changes in its government. The thousand years of national existence was celebrated by a millennial exhibition, historical processions, &c. at Budapest in 1896.

Language and Literature.—The Hungarians when they settled in their present land a thousand years ago brought their language ready with them, and this, although it has had since to borrow certain words from European languages to convey new ideas, has retained all its original features both as regards etymology and syntax. The origin of the Hungarian language can hardly be stated yet with certainty. Hungarian philologists are divided into two sections on the point, the 'Orientalists' maintaining its affinity with Turco-Tartaric languages, whilst the 'Finnists' contend, and for the present at least with far more general success, that it belongs to the Ugric branch of the Finnish group. By reason of the perfect harmony between vowels and consonants, and the very distinct articulation and pronunciation essential to it, Hungarian is considered a very musical language, particularly adapted to poetry and rhetoric. Its grammar, moreover, is so strikingly different from that of any other European language, and so rich in original characteristics, that it offers a very interesting field to students of comparative philology. It is acknowledged by them that it is well adapted to

express ideas with the utmost clearness, owing to the distinctness and immense variety of endings and the originality and flexibility of its roots. Among its characteristics are that it has no genders, and *declination* and *conjugation* are effected by means of suffixes only; that the verbs possess objective and subjective forms (e.g. *látok*, 'I see'; *látom*, 'I see him or her or it'; *látasz*, 'thou seest'; *látod*, 'thou seest him or her or it,' &c.); that it invariably places the surname before the Christian name. It is also noteworthy that there are absolutely no dialects in the Hungarian language, and scarcely any difference of pronunciation in the various parts of the country.

From the date of the establishment of the Hungarian kingdom the use of the Hungarian language was so much restricted that a Hungarian literature can hardly be said to have existed before the close of the 18th century. The introduction of Christianity by Italian and German priests in the 11th century made Latin the official language and the medium of intercourse between the educated classes, and this remained so to a great, though gradually diminishing, extent up to the third and fourth decade of the 19th century. There was a slight reaction in favour of Hungarian after the Reformation, but the language was not taught in schools till the year 1790, and parliament did not discontinue Latin until 1825. The oldest Hungarian literary record extant is a funeral oration dating from the year 1171; there are also some religious songs and dramatic 'mysteries' from the 14th century. The first lay poet of real merit, Baron Valentine Balassa, lived in the second half of the 16th, the first great epic poet, Zrínyi, in the 17th century.

The revival of literature began to take place only towards the end of Maria Theresa's reign. Lyric poetry was cultivated by Anyos, Virág, Baesanyi, and by Alexander Kisfaludy (1772-1844), Daniel Berzsenyi (1776-1836), Francis Kazinczy (1759-1831), and others, who not only added to the valuable stock of literature, but also enriched the language with new words and forms—Kazinczy excelling so much in this respect as to obtain the appellation of 'the recreator of the language.' Kolessey, orator, essayist, and poet, and Charles Kisfaludy (1788-1830), the founder of Hungarian drama, were the chief literary figures at the beginning of the 19th century. Hungarian poetry, however, cannot be said to have possessed much originality at this period; it was reserved to such men as Petöfi (1823-49), Vörösmarty (1800-55), Arany (1817-82), and Tompa (1819-68) to regenerate Hungarian poetry on national lines. This end was attained towards the period of the war of independence, since which Hungary has produced a number of minor poets, such as Sarosy, Szász, Vajda, Kiss, Reviczky, Abrányi, and Rudnyánszky. In dramatic literature Charles Kisfaludy was followed by Szigligeti (1814-78), whose extreme fertility enriched it by many exceedingly successful plays. The classic tragedy *Bánk Bán* of Katona (1792-1830), and *The Hunian Tragedy*, a dramatic poem, by Madach (1823-64), on the lines of Goethe's *Faust*, but no less original, deserve especial mention. Amongst their successors there is only one great dramatist—Gégor Csiky. The Hungarian theatres rely mainly on products of foreign literature—French, English and German.

In prose literature Hungary has produced many standard works. The founder of the real Hungarian novel was Baron Nicholas Josika (1794-1865), whose historical and social novels on the model of Sir Walter Scott's works achieved great success and popularity. Baron Joseph Eötvös (1813-71) cultivated the sentimental novel, and the novel with a purpose. But among authors of

fiction the highest rank is due to Maurice Jokai (q.v.), whose boundless imagination and profound humour have rendered him a favourite with readers in many countries beyond his own. Almost all his novels have been translated into German, many into Italian, French, English, and other languages. Beyond its own original productions it also possesses admirable translations of all the masterpieces in the world's literature, from the Bible, of which it possesses three versions, down through all ages and countries to Tennyson's poems. A collection of Shakespeare's plays is especially noteworthy, they having been translated by Hungary's greatest poets, including Petöfi (*Coriolanus*), Arany (*Hamblet, Midsummer-Night's Dream, King John*), Vörösmarty (*King Lear*), and others. It should be added that the best literary talent of the country is to a great extent connected with journalism.

See Fessler, *Geschichte der Ungarn* (new ed. by Klein, 1863-87); Majlath, *Geschichte der Magyaren* (2d ed. 1853); Sayous, *Histoire des Hongrois* (Par. 1876), and works by Horváth, Szalay, Toldy, &c.; also Vambéry, *Story of Hungary* (1886); Leger, *History of Austro-Hungary* (trans. by Mrs Birkbeck Hill, preface by Freeman, 1890); and Felbermann, *Hungary and its People* (1892).

Hunger. See APPETITE, DIGESTION.

Hungerford, a town of Berkshire, partly also in Wiltshire, is situated on the river Kennet, 26 miles WSW. of Reading. It is a hunting centre, and a favourite resort of anglers, having been even in Evelyn's time 'a town famous for its troutes.' In the town-hall (1870) is preserved a horn gifted to the town by John of Gannet in 1362. Pop. 2965.

Hünningen (Fr. *Huningue*), a town of Alsace, on the left bank of the Rhine, 2½ miles N. of Basel, is celebrated for its fish-breeding establishment (see PISCICULTURE). It was fortified by Vauban in 1679-81, but the works were finally destroyed in 1815. Pop. 1704.

Huns (Lat. *Hunni*, Gr. *Ounnoi* and *Chunnoi*), a nomad race of antiquity, whose remote ancestors were probably the Hing-nu, a people of Turki-h stock, who formed a powerful state in Mongolia in the 2d century B.C. In 177 they conquered another large nomad race, the Yue-chi, akin to the Tibetans, and drove them westward and southward, they themselves following. But about the dawn of the Christian era their political power fell to pieces and the tribesmen were scattered. One section, however, seems to have fled westwards and to have settled in the neighbourhood of the river Ural and the Volga. At all events, some three centuries and a half later the people known to classic and mediæval writers as Huns stepped upon the stage of history from that part of the world. About the year 372 they moved westwards again, under a leader called Balamir, and subdued first the Alani, who dwelt between the Volga and the Don, and then proceeded to attack the Ostrogoths, part of whom submitted somewhat tamely, whilst another part offered strenuous opposition, but were in the end compelled to submit likewise. This business completed, the Huns next invaded the territories of the Visigoths, and drove this people before them across the Danube, except one section, who, under Frithigern, sought permission of Valens, emperor of the East, to settle in his territories. The districts allotted by the Goths were occupied by the Huns. This, their first wave of invasion and conquest, seems then to have subsided; and, though it was followed by more than one smaller after-wave, it was not until about 430 that the second and greater wave began to gather head again in Rhnas or Rugulas. This chief acquired such power and influence that in 432 he imposed upon Theodosius II., emperor of Byzantium, an annual tribute of

350 pounds of gold. He was succeeded in 433 by his more illustrious nephew Attila (q.v.). With Attila's death, however, in 453, the power of the Huns crumbled to pieces amid the intestine strifes of his sons and generals, and the attacks of their foes round about. After a most disastrous defeat inflicted upon them in Pannonia in 454 by the combined armies of the Goths, Gepidae, Sævi, Herulians, and others, the tribesmen of the Huns rapidly dispersed. Some settled in the Dobrudja, others in Dacia, whilst the main body seem to have returned to the land from whence they came—viz. the region about the river Ural. Some authorities identify these with the later Bulgarians, who about the end of the 5th century had risen into a powerful state on the Volga, and sent off conquering bands to the south-west, who finally settled in the modern Bulgaria.

The Huns are described as being of a dark complexion, deformed in appearance, of uncouth gesture and shrill voice. 'They were distinguished,' says Gibbon, 'from the rest of the human species by their broad shoulders, flat noses, and small black eyes deeply buried in the head; and, as they were almost destitute of beards, they never enjoyed either the manly graces of youth or the venerable aspect of age. A fabulous origin was assigned worthy of their form and manners—that the witches of Scythia, who for their foul and deadly practices had been driven from society, had united in the desert with infernal spirits, and that the Huns were the off-spring of this execrable conjunction.' Like the Mongols, they were essentially a race of horsemen; they fought with javelins tipped with bone, with sabres, and with slings or lassoes. They ate herbs and half-raw meat, which they first used as saddles; and they clothed themselves with the skins of wild animals.

The White Huns or Ephthalites or Hephthalites are by some regarded as a branch of the Hing-nu, though others make them the descendants of the ancient Royal Scythians, identifying them with the Barsileens, the allies of the Khazars. Whatever be their real origin, they were certainly established in ancient Bactria and the adjoining districts, between the Oxus and the Caspian, at a period contemporaneous with Attila's career. From the third decade of the 5th century onwards for about 120 years they were engaged in constant wars with their neighbours on the south, the Persians. In 484 the Ephthalites routed them in a fierce battle, in which Peroz, king of Persia, was amongst the slain. But their power seems to have been finally broken about 560 by the all-conquering Turks on their way to Asia Minor and Constantinople.

See De Guignes, *Histoire Générale des Huns* (vol. i. 1756); Neumann, *Die Völker des südlichen Russland* (2d ed. 1855); Thierry, *Histoire d'Attila* (4th ed. 1874); and Howorth, in *Jour. Anthropol. Inst.* (1872-74).

Hunstanton, a watering-place of Norfolk, on the Wash, 18 miles NE. of King's Lynn by a railway (1862). It has a broad beach of firm sand, and good bathing and sea-fishing, a pier, and a splendid decorated church (c. 1330). Hunstanton Hall, dating from the Tudor period, but greatly injured by fire in 1853, was the seat of Sir Roger L'Estrange. A lighthouse (1840) lifts a fixed light to an altitude of 109 feet, and shows it for a distance of 16 miles. Pop., with Barrett Ringstead, 1725.

Hunt, HENRY, surnamed 'Orator Hunt,' was born at Upavon, in Wiltshire, on 6th November 1773. He was a well-to-do farmer, but in 1800 his hot temper embroiled him with Lord Bruce, the commandant of the Wiltshire yeomanry, which brought him six weeks' imprisonment. He came out of gaol a hot Radical, and spent the rest of his life travelling about the country addressing

the people on behalf of the repeal of the Corn Laws and as an advocate of parliamentary reform. In 1819, on the occasion of the Peterloo massacre, he delivered a speech, which cost him three years' imprisonment. He died at Alresford, in Hampshire, on 13th February 1835.

Hunt, JAMES HENRY LEIGH, poet and essayist, was born at Southgate, near Edmonton, on 19th October 1784. His father, Isaac Hunt (1752-1800), a Barbadian, being driven by the Revolution from Philadelphia to London, gave up law for the church, but lapsed into bankruptcy and Universalism. Leigh Hunt spent eight years at Christ's Hospital, and left at fifteen as first 'Deputy-Grecian,' debarred by a stammer from further promotion. He was a clerk first under one brother, an attorney, and next for four years in the War Office, writing meanwhile much dramatic criticism: in 1808 with another brother, a printer, he set up the *Examiner*; and in 1809 wedded Marianne Kent (1788-1857). The *Examiner's* tone was Radical, and, after several government prosecutions in 1813 for a libel on the Prince Regent (he had called him a 'corpulent Adonis of fifty'), Leigh Hunt was sentenced to a fine of £500 and to two years' imprisonment in Surrey gaol. There he 'scattered urbanity,' played battledore with his children, received hosts of visitors, and turned his cage into a 'bower of roses.' In November 1821 with his wife and seven children he sailed for Italy, but landed at Leghorn only on 1st July. He went on Shelley's invitation to help him and Byron to found the quarterly *Liberal*. Just a week later Shelley was drowned; Leigh Hunt and 'my noble friend' failed somehow to pull together; the *Liberal* died in its fourth number; and by 1825 the family was back at Highgate. Changes of residence, to Upper Cheyne Row, Chelsea, in 1833, to the 'old court suburb' of Kensington in 1840, and to Hammersmith in 1853—these are thenceforth the chief events in Leigh Hunt's life. It was one of ceaseless activity and as ceaseless embarrassment, for he *never* knew his multiplication table. From 1844, however, Sir Percy Shelley allowed him £120 a year, and in 1847 he received a pension of £200. He died on a visit to Putney, 28th August 1859.

The 'Cockney poets,' so the critics dubbed Keats and Leigh Hunt. That the two should ever thus have been bracketed may now seem strange, for Leigh Hunt's poetry now is little known. And yet it is better than much, maybe most, of the newer poetic vogues. Its charm lies in a prettiness as of childhood; its wit and cleverness and wine-like sparkle have ever a smack of precocity. Narrative verse is his forte, his foible jauntiness. His translations are among the choicest of their kind; he transports the southern vintages to England, and their colour and flavour improve instead of losing by the voyage. As his poems, so his prose; his essays are always worth reading, but only after the *Essays of Elia*. Leigh Hunt's writings, indeed, are less memorable than his friendships—with Keats and Shelley, as also with Lamb, Byron, Moore, Coleridge, Dickens, Carlyle, and a whole galaxy of lesser luminaries. Our knowledge of them, and especially the first two, is largely derived from his.

In his excellent *List of the Writings of Ha'ltitt and Leagh Hunt* (1868) Mr Alexander Ireland chronologically arranges with notes, &c., seventy-nine works by the latter, including *Jocundia* (1801), *The Feast of the Poets* (1814), *The Story of Rowan* (1816), *Fadlan* (1818), *Captain Swind and Captain Pen* (1835), and *The Palfrey* (1842); besides much in prose, as *Lord Byron and his Contemporaries* (1828), *See Ralph Esch* (1832), *Imagination and Fancy* (1844), *Wit and Humour* (1846), *Stories of the Italian Poets* (1846), *A Jar of Honey from Mount Hybla* (1848),

and *The Old Court Suburb* (1855). See Leigh Hunt's *Autobiography* (3 vols. 1850; revised ed. 1860) and *Correspondence* (2 vols. 1862), Forster's *Life of Dickens* (for the unkindly 'Harold Skimpole' episode), a capital article in the *Cornhill* (1. 1860), and one by Prof. Dowden in Ward's *English Poets* (iv. 1880); and sketches by Cosmo Monkhouse (1893) and B. Johnson (1896).

Hunt, THOMAS STERRY, an American chemist and geologist, born at Norwich, Connecticut, 5th September 1826, was assistant to the elder Silliman at Yale College, and from 1847 to 1872 chemist and mineralogist to the Canadian Geological Survey. He was also professor of Chemistry at Laval University (1856-62) and at McGill University (1862-68); from 1872 to 1878 he held the chair of Geology in the Massachusetts Institute of Technology. In 1848-51 he contributed a series of papers on theoretical chemistry to the *American Journal of Science*: in organic chemistry his name is identified with a system essentially his own. His researches into the composition of rocks were of great importance. In 1859 he invented the green ink with which Greenbacks (q.v.) are printed. He was made an officer of the Legion of Honour in 1867, and became an F.R.S. (1859), and LL.D. of Cambridge (1881), and received many other distinctions. At his death, 12th February 1892, he had published over 200 papers and several larger works on chemistry and mineralogy.

Hunt, WILLIAM HENRY, English painter in water-colours, was born in London, March 28, 1790. He was one of the creators of the English school of water-colour painting, Mr Ruskin pronouncing him to be among the greatest colourists of the school. His subjects are very simple—'Peaches and Grapes,' 'Old Pollard,' 'Basket of Plums,' 'Roses,' 'Wild Flowers,' 'Tramps at Home,' 'A Farmhouse Beauty,' 'Fast Asleep,' &c., but they are conceived in a finely poetical spirit, and present the perfection of finish. He died 10th February 1864.

Hunt, WILLIAM HOLMAN, painter, was born in London, 2d April 1827. In his early years he was engaged in business, but in 1845 he was admitted a student of the Royal Academy. In the following year he exhibited his first picture, 'Hark!' a child holding a watch to her ear; this was followed by scenes from Dickens and Scott, and by the more important 'Flight of Madeline and Porphyro,' from Keats' *Exc of St Agnes* (1848). At this period Mr Hunt shared a studio with Dante Gabriel Rossetti, and the pair, along with Millais and a few other earnest young painters, inaugurated the 'Pre-Raphaelite Brotherhood,' of which the members aimed at detailed and uncompromising truth to nature in their rendering of visible things, and at a vivid and unconventional realisation in their treatment of imaginative subjects. In 1850 Mr Hunt contributed to *The Germ*, the short-lived magazine of the brotherhood, two etched subjects illustrating Woolner's poem 'My beautiful Lady,' and at a later period he designed various woodcuts, in particular a remarkable series for the illustrated Tennyson of 1857. The first of the painter's works executed in the Pre-Raphaelite manner was 'Rienzi vowing to avenge the Death of his Brother' (1849), in which the principal figure was painted from Rossetti. It was followed by 'A Converted British Family sheltering a Christian Missionary from the Pursuit of the Druids' (1850); 'Valentine rescuing Sylvia from Proteus,' from the *Two Gentlemen of Verona* (1851); 'The Hiring Shepherd' (1852); and 'Claudio and Isabella,' a tragic and impressive prison-scene from *Measure for Measure* (1853)—works very fresh and original in conception, and carried out with the most careful elaboration; while 'Our English Coasts,' known also as 'The

'Strayed Sheep' (1853), was a remarkable effort in landscape art, realising with exceptional power an effect of vivid sunlight, and combining in a wonderful manner detail and definition with a sense of distance and atmosphere. 'The Light of the World' (1852-54), of which a smaller replica was executed in 1856, ranks as one of the most impressive symbolical works of the century; it is now in the chapel of Keble College, Oxford. 'The Awakened Conscience' aimed to point a moral by means of a scene from modern life. On the completion of the last named picture in the beginning of 1854 Mr Hunt started for Palestine, with the intention of studying eastern life, and realising the incidents of the biblical history with the closest possible accuracy to local colouring and the surroundings amid which they occurred. The result of several prolonged visits to the East appeared in 'The Seapegoat' (1856); 'The Finding of Christ in the Temple' (1860), presented in 1896 to the Birmingham Art Gallery; 'The Shadow of Death' (1874), now in the Corporation Gallery, Manchester; and 'The Triumph of the Innocents' (1875-85), executed in two versions; while the passionate and splendidly coloured 'Isabella and the Pot of Basil' was the result of a visit to Florence in 1867. In 1881 he painted a portrait of Professor Sir Richard Owen; in 1888-89 'The Choristers of Magdalen College, Oxford, singing the May Day Hymn'; and in 1899 the 'Miracle of Sacred Fire at Jerusalem.' In 1886 he contributed to the *Contemporary Review* a series of autobiographical papers; and in the same year over thirty of his works were exhibited in the Fine Arts Society's rooms.

Hunter, JOHN, physiologist and surgeon, was born at Long Calderwood, near East Kilbride, in Lanarkshire, 13th February 1728, and was the youngest of ten children. One of his sisters, Dorothea, was married to Dr James Baillie, professor of Divinity in the university of Glasgow, and was the mother of Matthew and Joanna Baillie (q.v.). His brother William's fame led John to apply for and obtain the situation of assistant in the dissecting-room. He studied surgery under Cheselden in 1749-50 at Chelsea Hospital, and subsequently under Pott. After a year at Oxford he entered St George's Hospital as surgeon's pupil in 1754, afterwards becoming house-surgeon and partner with his brother in the anatomical school. After ten years' hard work of this kind his health gave way, and in 1759 he entered the army as staff-surgeon, and served at Belleisle and in the Peninsula. Peace being proclaimed in 1763, he returned to London and, starting the practice of surgery, devoted much time and money to comparative anatomy. In 1767 he was elected a Fellow of the Royal Society, and in the following year was appointed surgeon to St George's Hospital, an appointment which enabled him to take pupils, of whom one of the earliest was Jenner. His practice at this time was increasing rapidly, but his income never reached £1000 a year until 1774. In 1776 he was appointed surgeon-extraordinary to the king. In 1785 he built his museum, with lecture-rooms, and in the same year he tried his famous operation for the cure of aneurism—that of simply tying the artery at a distance from the tumour, and between it and the heart. In 1786 Hunter was appointed deputy-surgeon-general to the army; in 1787 he received the Copley medal from the Royal Society. He was now universally acknowledged by all the younger surgeons as the head of his profession; but most of his contemporaries looked upon him as little better than an innovator and an enthusiast. He died 16th October 1793, and was buried in the church of St Martin-in-the-Fields, whence, thanks

to Frank Buckland, his remains were translated in March 1839 to Westminster Abbey. Some idea of Hunter's diligence may be gathered from the fact that his museum contained at the time of his death 10,563 specimens and preparations illustrative of human and comparative anatomy, physiology, pathology, and natural history. He died in comparative poverty, and his collection was purchased by government, two years after his death, for £15,000, and was presented to the Royal College of Surgeons.

In addition to the numerous papers contributed to the *Transactions* of the Royal and other learned societies, he published the following independent works: *The Natural History of the Human Teeth* (1771-78); *A Treatise on the Venereal Disease* (1786); *Observations on Certain Parts of the Animal Economy* (1786); and *A Treatise on the Blood, Inflammation, and Gunshot Wounds* (1794). See Palmer's edition of his works (1835), Mather's *Two Great Scotsmen* (1894), and the Life by S. Paget (1897).

Hunter, WILLIAM, anatomist and obstetrician, an elder brother of John Hunter, was born at Long Calderwood, Lanarkshire, 23d May 1718. Originally educated for the church at Glasgow University, he studied medicine for one session (1740-41) at Edinburgh, and then proceeded to London, where he went through a long training in anatomy at St George's Hospital and elsewhere. In 1747 he was admitted a member of the Corporation of Surgeons, ultimately confining his practice to midwifery. In 1762 Hunter was consulted by Queen Charlotte, and two years later was appointed physician-extraordinary to her majesty. Elected a Fellow of the Royal Society, he in 1768 became professor of Anatomy to the Royal Academy. In 1770 he removed to Great Windmill Street, where he had built a house, in connection with which were an amphitheatre for lectures, a dissecting-room, and a museum which contained not only his anatomical preparations, but many objects of natural history and a cabinet of very rare medals and coins. Hunter and his brother John were for many years estranged, owing to a dispute as to the priority of certain discoveries; but the quarrel was made up while William was on his death-bed. He died 30th March 1783. His museum was bequeathed to his brother-in-law, Dr Baillie, and after him, with an endowment of £8000, to Glasgow University (q.v.). His most important work, *An Anatomical Description of the Human Gravid Uterus and its Contents*, did not appear in its complete form till after his death.

Hunter, SIR WILLIAM WILSON, statistician, was born on 15th July 1840, educated at the universities of Glasgow, Paris, and Bonn, and in 1862 entered the civil service of India. His first important office, that of superintendent of public instruction in Orissa (1866-69), gave him the opportunity to write *Annals of Rural Bengal* (1868) and *Comparative Dictionary of the Non-Aryan Languages of India and High Asia* (1868). Then, after filling the responsible offices of secretary to the government of Bengal and the supreme government of India, he was in 1871 appointed director-general of the statistical department of India. The Indian census of 1872 was his first work in his new position. His later books include the compendious *Imperial Gazetteer of India* (9 vols. 1881; 14 vols. 1886-88), *Orissa* (1872), *Life of Lord Mayo* (2d ed. 1876), *Statistical Account of Assam* (1880), *Famine Aspects of Bengal Districts* (1874), *Indian Mussulmans* (1871; 3d ed. 1876), *The Indian Empire* (2d ed. 1886). He received the Star of India in 1878, and in 1887 was knighted. In 1890-96 he edited a series of Lives of 'Rulers of India,' to which he himself contributed *Dalhousie*. *The Old Missionary* (1895) is a touching story of Indian life. He died at Oaken Holt Hall, Oxford, 7th February 1900.

Hunting. See FOXHUNTING, STAG, and the articles on the other animals hunted.

Huntingdon. SELINA, COUNTESS OF, was the second of three daughters and co-heiresses of Washington Shirley, second Earl Ferrers, and was born August 24, 1707. She married the Earl of Huntingdon in 1728, and became a widow in 1746. Adopting the principles of the Calvinistic Methodists, the founder of which sect was the famous George Whitefield, she made that eminent preacher one of her chaplains, and assumed a leadership among his followers, who came to be known as 'The Countess of Huntingdon's Connection.' Her labours at home increased with her years. For the education of ministers she established and maintained a college at Trevecca, in Brecknockshire (removed in 1792 to Cheshunt, Herts.); and built, or became possessed of, numerous chapels in different parts of the country, the principal one being at Bath. She died June 17, 1791. By her will, dated January 11, 1790, she created a trust, bequeathing her chapels, then sixty-four in number, to the care of four persons. Most of them have become, in doctrine and practice, almost identical with the Congregational churches.

Huntingdon. the county town of Huntingdonshire, on the left bank of the Ouse, and the Ermine Street of the Romans, 59 miles N. of London. It became the seat of a royal castle in 917, and was incorporated in 1189. It has breweries, brickworks, carriage-works, and misery gardens. Here Oliver Cromwell was born (1599), and here the poet Cowper lived for a couple of years (1765-67); the chronicler, Henry of Huntingdon (q.v.), was Archdeacon of Huntingdon. With the municipal borough of Godmanchester (pop. 2095), on the opposite bank, it formed a parliamentary borough, returning till 1867 two members, till 1885 one. Pop. (1851) 3882; (1891) 4346.

Huntingdonshire, an inland county of England, 30 miles long, and 23 broad, is bounded on the N. and W. by Northampton, Cambridge, and Bedford shires. Area, 359 sq. m.; almost the whole of which is arable or in pasture. Pop. (1891) 37,568; (1861) 64,250; (1891) 57,761. Huntingdonshire has no hill-ranges of any importance, and is watered chiefly by the Nene, which forms its northern boundary, and the Ouse; in the fen-district in the north-eastern part of the county, forming part of the Bedford Level (q.v.), there were formerly some large lakes or meres, notably Whittlesea, Ramsey, and Ugg; but these have been drained and reclaimed for cultivation. The soil consists principally of clay, with, in places, sand, gravel, and peat earth, the latter being almost wholly confined to the fen-district. Huntingdonshire comprises four hundreds and the municipal boroughs of Huntingdon, Godmanchester, and St Ives, with part of the city of Peterborough, the greater portion of which is however in Northamptonshire. It contains 103 parishes, is almost entirely in the diocese of Ely and the South-eastern Circuit, and returns two members to parliament. A peculiarity in its civil government is that it is included under the same shrievalty with Cambridgeshire, the sheriff being annually chosen in rotation from the county of Cambridge, the Isle of Ely, and this county. Of its earlier inhabitants Huntingdonshire has numerous traces; two Roman roads traverse it; at Alwalton, Earith, and Chesterton are remains of camps, the construction of which is also ascribed to the Romans; and in many places Roman remains, as pottery, coins, &c., have been found. Among places of interest in the county those most worthy of mention are the ruins of Ramsey Abbey and Buckden Palace, the latter being formerly the residence of the bishops of Lincoln; Hinchinbrook

House, anciently the seat of the Cromwell family; Kimbolton Castle, the seat of the Duke of Manchester, where Queen Catharine resided for some time after her divorce from Henry VIII.; Horeham Hall, the residence of the Princess Elizabeth during the reign of her sister Mary; Denton, the birth-place of Cotton the antiquary; Little Gidding, the seat of Nicholas Ferrar's community; and Brampton, where lived for some years Samuel Pepys.

Huntly, a town of Scotland, 41 miles NW. of Aberdeen. In the vicinity is the ruin of Huntly Castle, the seat of the earls and marquises of Huntly (see GORDON). Huntly is the birthplace of Dr George Macdonald. Pop. 3760.

Huntsville, capital of Madison county, Alabama, in the valley of the Tennessee, 10 miles N. of the river, and 212 miles ESE. of Memphis by rail. It has an ice-factory, a foundry, and manufactures of cotton, cotton-seed oil, and flour. Pop. (1880) 4977; (1890) 7995.

Hunyady Janos. John Corvinus Hunyady, governor of Hungary, one of the greatest war-captains of his age, was born towards the close of the 14th century. His origin is wrapped in mystery, the current legend being that he was a son of the Emperor Sigismund by a Wallachian lady. His life may be succinctly described as one unbroken crusade against the Turks. During the period 1437-56 he was the shield of Hungary, not only against external foes, but against the lawlessness of the nobles at home. The principal moments in his celebrated contest with the foes of Christendom are his expulsion of them from Transylvania in 1442; his brilliant campaign south of the Danube in 1443; his defeat in the bloody battle of Varna, 1444; and that at Kossovo in 1448; but his most glorious achievement was the storming of Belgrade (1456). Shortly afterwards Hunyady died of dysentery. During the minority of Ladislaus V. the great captain acted as governor of the kingdom (1445-53). Hunyady left two sons, Ladislaus and Matthias—the former of whom was beheaded at Buda on a charge of conspiracy; the latter succeeded to the crown of Hungary (q.v.).

Hunza-Nagar, the valley (containing the forts of Hunza and Nagar) of a river running into the Gilgit, at the extreme NW. corner of Cashmere. Together with Kanjut, the upper part of the same valley, it became British in 1891.

Huon Gulf. See NEW GUINEA.

Huon of Bordeaux, one of the Charlemagne cycle of romances. In its present form it is a prose version, dating from 1454, of a poem current about the end of the 12th century, and sometimes ascribed, without grounds, to the trouvère Huon de Ville-neuve. In the story, Huon, Duke of Guienne, one of the paladins of Charlemagne, in self-defence kills Charlot, son of Charlemagne, and is in consequence condemned to die, but his life is granted on the hard condition that he brings back from Bagdad some of the Saracen emir's teeth and beard after having kissed his daughter before his face. The dwarf Oleron gives him a magical cup and horn, one blast of which in the hour of peril brings him and 100,000 warriors to Huon's aid. Moreover, the princess Esclarmonde, like Medea, lightens his labours by falling in love with him, so that at last he is completely successful, and returns with her as his wife to clear himself before Charlemagne. The prose romance was printed at Paris in 1516; and Lord Berners' English translation, by Wynkyn de Worde, in 1534 (ed. by S. L. Lee for E. Eng. Text Soc., 1882-87; simplified by Steele, 1896).

Hū-pei, one of the central provinces of China, watered by the Yangtse. See CHINA.

Hurd, RICHARD, English prelate and writer, named the 'Beauty of Holiness' on account of his comeliness and piety, was born at Congreve, in Staffordshire, January 13, 1720, and studied at Emmanuel College, Cambridge, of which he became a Fellow in 1742. In 1749 appeared his first notable production, *Commentary on Horace's Ars Poetica*. In connection with this work Gibbon wrote of the author, 'I know few writers more deserving of the great but prostituted name of critic; but, like many critics, he is better qualified to instruct than to execute.' In 1750, on the recommendation of Warburton, of whom he was a life-long friend and admirer, and whose *Works* he edited in 1788, he was appointed one of the Whitehall preachers. He afterwards (1774) became Bishop of Lichfield and Coventry, but exchanged this see for Worcester in 1781; in 1783 he declined the archbishopric of Canterbury. He died May 28, 1808. His principal works are *Dissertations on Poetry, &c.* (1755-57); *Dialogues on Sincerity, Retirement, the Golden Age of Elizabeth, and the Constitution of the English Government* (1759), his most popular book; *Letters on Chivalry and Romance* (1762); *Dialogues on the Uses of Foreign Travel* (1764); and *An Introduction to the Study of the Prophecies concerning the Christian Church* (1772). See Hurd's *Works* (8 vols. 1811) and *Memoirs* by Kilvert (1860).

Hurdwār. See HARDWAR.

Hurdy-gurdy, a very old musical instrument of the stringed kind, something between a guitar and a lute in appearance. It has four or six catgut or wire strings attached to screw-pegs in the head; two of the strings stretch over the sounding-board to the tailpiece, and are sounded by a wooden wheel (under the cover *a* in the fig.) charged with rosin, which is turned by means of a handle with the player's right hand. The

Hurdy-gurdy.

strings are 'stopped' by an ingenious arrangement of keys, *b*, manipulated with the left hand. The remaining strings are stretched out of reach of the keys, and are tuned as drones. The instrument has a range of two octaves from the tenor G upwards. The rustic simplicity of its music made it at one time a great favourite among the peasantry of a great part of Europe (see Engel's *Musical Instruments*). The name hurdy-gurdy is also sometimes applied to the mechanical pianos familiar on the streets. The word was probably coined to express contempt of the instrument.

Hurlingham, at Fulham (q.v.) in Middlesex, on the Thames, below the bridge, the headquarters of Pigeon-shooting (q.v.) and polo.

Huron, the second in area of the five great lakes on the frontier between the United States and Canada, is connected at the north-west by St. Mary's River with Lake Superior, and through the strait of Mackinaw with Lake Michigan. On the south it has an outlet by way of the St. Clair River. It is bounded on the W. and SW. by Michigan, and elsewhere by Ontario. The lake is divided into two unequal parts by the Cabot's Head peninsula and Grand Manitoulin Island, the parts to the north being called North Channel and Georgian

Bay. Its extreme length is 263 miles; its greatest breadth, exclusive of Georgian Bay, 105 miles; average breadth, 70 miles. The area of the entire lake is 23,800 sq. m.; it is larger than Lake Michigan, although its basin is smaller. According to the perfected levels of the United States Lake Survey, its mean elevation is 581 $\frac{1}{2}$ feet above sea-level; it is 20 $\frac{1}{2}$ feet below Lake Superior, and 8 $\frac{1}{2}$ above Lake Erie. Huron has a mean depth of about 250, and a maximum depth of 750 feet. There is an average difference between high and low water (due to winds and rain) of 1 $\frac{1}{2}$ foot. Huron, like the other lakes, is subject to violent storms. It contains about three thousand islands, nearly all Canadian; some of them are of considerable size. The waters are very clear and pure, and abound in fish. There are numerous good harbours and roadsteads, most of them on the Canadian side; at Sand Beach, Michigan, there is a harbour of refuge. See Crossman's *Chart of the Great Lakes* (Milwaukee, 1888).

Huronian, a subdivision of the Archaean rocks of Canada. See ARCHAIC SYSTEM.

Hurons, a once powerful tribe of American Indians, belonging to the Huron-Iroquois family. In the early part of the 17th century the Hurons numbered about 30,000 persons, living in twenty-five villages within a small territory near Georgian Bay. By the end of the century the tribe had been nearly destroyed by the Iroquois, famine, and disease; and in 1693 the few survivors were removed by the French to Petite Lorette, near Quebec. Here two or three hundred descendants still live; but very few are of pure blood, and all are Catholics, and have abandoned their own language for French.

Hurricane. See STORMS, and WIND.

Hursley, a village of Hampshire, 5 miles SW. of Winchester. John Keble, author of the *Christian Year*, was vicar here from 1835 till his death in 1866. In 1848, with the profits of that celebrated work, he restored the church, which is rich in modern stained glass. Keble himself lies buried in the churchyard, and in the chancel is the grave of Richard Cromwell.

Hurstmonceaux, a village of Sussex, 5 miles N. of Pevensey, with the extensive ivy-covered ruins of a fine castle, built of brick under Henry VI. by Sir Roger de Fienes, one of the heroes of Agincourt. It passed in 1727 into the hands of the Hares or Hare-Naylors. The then head of the house, Bishop Hare, took good care of the estate, but its resources were shamefully squandered by the two succeeding heirs, and about the close of the century the castle was unroofed and its valuable contents sold off at a six weeks' sale. A modern mansion was built near its ruins. The famous Broad Church leader, Archdeacon Hare (q.v.), was rector of the parish from 1832 till 1855, and lies buried in the churchyard. The church is Early English, with Perpendicular windows, and contains, among other ancient monuments, the fine canopied altar-tomb of the second Lord Daere.

Hurstpierpoint, a market-town of Sussex, 8 miles N. by W. of Brighton. Here is St. John's College (1849), a middle-class school in connection with Lancing (q.v.). Pop. of parish, 2736.

Husband and Wife. The marriage-contract is for the joint lives of the parties, and comes to an end with the death of either; they cannot themselves put an end to it or escape from its obligations, except by means of a legal Divorce (q.v.) or Separation (q.v.). It is a not uncommon delusion among working-people that if a husband or wife runs away or disappears the deserted

spouse may lawfully marry again; but this is not the case. If husband or wife disappears, and is not heard of for seven years, the party deserted may marry again without incurring the risk of a conviction for bigamy; but even in this case the second marriage is a nullity if the first husband or wife is alive at the time when it is solemnised. During its continuance the contract has important effects on the rights and mutual relations of the parties. The husband is, in law, the head of the house; he has a right to choose the family domicile, and to require his wife to cohabit with him there. He may sue and be sued, enter into contracts, and dispose of his property as freely as a single man; the modern English law permits him to bequeath his property without making any provision for his wife, and to bar her claim to dower in disposing of his landed estate. He is bound to maintain his wife and children; if, being able to maintain them, he neglects to do so, his goods may be seized and sold by the parish authorities, or he may be imprisoned for one month as a disorderly person. If he deserts his wife and family, leaving them to become a charge on the parish, he may be treated as a rogue and vagabond, and imprisoned for three months. If his wife leaves him without just cause he is not bound to support her, and he may compel her to return by bringing an action for the restitution of conjugal rights. But if there is just cause for separation—if, for example, the husband is guilty of what the law deems cruelty—as keeping a mistress in the house, or starving and beating his wife—the wife is not bound to return, and the husband will be liable for the price of necessaries ordered by her on his credit. When the parties are living together, the question whether the wife has authority to pledge her husband's credit must be decided on consideration of all the facts of the case. No authority is implied from the mere fact of marriage, and tradesmen are not safe in relying on the wife's assertion in such cases; but a woman who keeps her husband's house may be taken to have authority to order food and clothing suitable to their rank in life, unless the husband has taken steps to protect himself from liability, as, for example, by giving notice to the tradesman not to trust his wife. Much misconception prevails in regard to the extent of a wife's authority; and there is a class of small traders, called tallymen, who take advantage of the popular ignorance. They persuade working-men's wives to purchase dresses or other goods, to be paid for by instalments; on default in payment, the husband is often made to pay heavily for his wife's improvidence, though it may be that in law he is not liable at all. In such a case it is sometimes best for the husband to allow himself to be taken into a county court, where the judge will see that the tallyman gets no more than his due. A policy of insurance, effected by a husband on his own life for the benefit of his wife or children, is protected against his creditors.

A married woman is called in law French *feur coverté*; she is protected by her husband and under his control, and the two are, for many purposes, one person in law. If she commits a crime in his company or under his coercion the crime is his, not hers; he is punished and she escapes; but this rule does not apply to treason, murder, and other heinous offences. Formerly she could sue only by her next friend, and if she was sued, her husband was joined; but modern rules permit her to sue and defend alone. At common law the wife's personal property vested in the husband; he took the profits of her land during the marriage; and if an heir was born of the marriage the husband became 'tenant by the courtesy of England,' and held the land for his own life if he survived his

wife. He assumed her liabilities also, and might be sued for her ante-nuptial debts. But at an early period courts of equity decided that, where property was given for the separate use of a married woman, she herself should have the use and disposition of it; if such property came into the husband's hands he held it as trustee for her. This doctrine of separate use has been greatly extended by the Married Women's Property Acts of 1870, 1874, and 1882. These acts do not apply in their integrity to women married before they came into operation; it is therefore necessary in ascertaining the rights of a wife to know when she was married. Under the Act of 1882 a wife holds her realty and personality as her own separate property; she may enter into contracts relating to it, and dispose of it as freely as a *jure sole*. Her property is liable for her separate debts, and execution may issue against it, though not against her person. Her husband is not liable for her ante-nuptial debts, except to the value of any property which comes to him through her. She may insure her own or her husband's life for her separate use. All earnings of the wife are protected by the Married Women's Property Acts; and under an earlier act a woman separated from her husband may obtain a magistrate's order protecting her earnings. A woman who has property may be made liable under the poor-law for the maintenance of her husband and children.

Marriage is a 'valuable consideration,' and a settlement of property made in pursuance of the contract stands good even against creditors. Provisions for the benefit of children are 'within the scope of the marriage bargain.' A post-nuptial settlement, unless made in fulfilment of a previous bargain, is not made in consideration of marriage; it may be upset by creditors like any other voluntary transfer of property.

The old rule that husband and wife are one person has been so far set aside by legislation that some of the consequences deduced from it are now doubtful in point of law. Formerly, if property were given in equal shares to husband and wife and a third person, the husband and wife took half and the third person the other half; and it has been decided that this rule applies even in a case of a gift or will made since 1882. Again, it used to be held that a woman could not be convicted of stealing her husband's goods; but sections 12 and 16 of the Act of 1882 enable married persons to prosecute one another. Except in cases within the act, and cases of personal injury inflicted by one spouse on the other, husband and wife cannot give evidence in criminal proceedings against one another; thus, on a trial for bigamy, the first wife cannot be called to prove her own marriage. In civil actions the spouses are competent witnesses for and against one another.

A husband surviving his wife is entitled to her personal property not disposed of by her, and has a paramount claim to administer her estate. A wife surviving her husband is entitled to one-third of his personality not disposed of by him, and she has a claim to administer; she has also a claim to dower—i.e. a life-estate in one-third of his land, unless the claim to dower has been barred.

In the United States the law of husband and wife is based upon the common law of England as above explained. The legislation of the different states, however, has diverted the common law rules with somewhat varying effect in the direction of the recent English statutes, and considerably in advance of them upon the same lines. A long series of statutes, beginning at an earlier period than in England about 1844—has now swept away the disabilities laid upon married women by the common law. Wives are now generally able to hold

property, real and personal, in their own right, to enter into contracts, and to sue in their own names. They are on substantially an equal footing with unmarried women; and it is not uncommon for married women to carry on business in their own names and with full power to enforce contracts. The old rule that husband and wife are one person in law is now practically obsolete. A wife may contract with her husband and may sue him upon the contract, in some states directly, in others through the intervention of a guardian or trustee. The independent position conceded by the law to married women in the United States is a chief cause of the recent increase and frequency of divorce in that country.

The law of Scotland has specialties of its own. The husband is the legal curator of his wife; and if at the time of the marriage she have another curator, the office of this last expires. Thus actions brought against a wife must be brought also against the husband for his interest, and the husband must concur in actions raised by the wife. The husband further in his capacity of curator signs as co-consentor to the wife's deeds. The husband is liable for the ante-nuptial debts of his wife; but under the Married Women's Property Act, 1877, this liability is limited to the amount by which the husband receives profit from the marriage. The wife has power to bind her husband in so far as she acts with his authority and as his agent. With regard to furnishings to the family, the wife is presumed by law to be the manager of the household, *proposita negotiis domesticis*, and so to be authorised to bind the husband. This presumption can only be removed by inhibition or by private notice from the husband to tradesmen. The *ius mariti*, or husband's right, had the effect of transferring to the husband upon marriage all the personal property of the wife belonging to her at the time of the marriage, or acquired by her during its subsistence. It also gave the husband the rents and yearly income of her heritable property; but it did not extend over the wife's paraphernalia. Besides the *ius mariti*, the husband possessed the right of administration of his wife's heritable property. In virtue of this right, the husband's consent is necessary to all acts by which the wife deals with her heritage. Both of these rights may be renounced by the husband or excluded by special contracts and settlements; and with regard to marriages that come under the Married Women's Property Acts these rights are to a great extent extinguished.

The effect of the Married Women's Property Act, 1882, is to abolish the *ius mariti* altogether with regard to marriages contracted after its date; to vest in the wife as her own separate estate all the movable property acquired by her at any time. The statute practically does away with the husband's right of administering the income of the wife's estate. The earnings of married women and those of women living separate from their husbands are protected by prior statutes against the husband and his creditors. On the death of a wife the surviving husband has a life interest, called courtesy, in her heritable estate; and has the same interest in her movable estate as a widow has in the movable estate of her deceased husband—i.e. a share amounting to one-half if there are no children, and one-third if there are. This share, when it falls to a widow out of the estate of her deceased husband, is hers by virtue of the *ius relicte* or relic's right. The widow has further, where she has no conventional provision, a right to the terec, which is a life interest of a third of the husband's heritable property.

See works by Lush (1881), Macqueen (1885), Schonler (Boston, 1882), Thicknesse (1884), and Crawley (1892).

Husch, or HUSI, a town of Moldavia, near the Pruth, 38 miles SSE. from Jassy, cultivates tobacco and the vine. It was founded by fugitive Hussites in the 15th century. Here was signed in 1711 the treaty between the Russians and Turks by which Peter the Great rescued his army, surrounded by the foe. Pop. 18,500.

Huskisson, WILLIAM, statesman and financier, was born at Birtsmorton Court, in Worcestershire, 11th March 1770, and in 1783 was sent to Paris to study medicine. He was present at the storming of the Bastille, and as a member of the Club of 1789 attracted attention by a speech on the assignats. Returning to England, he was appointed in 1795 under-secretary in the Colonial Department. Next year he entered parliament for Morpeth as a supporter of Pitt. Being returned for Liskeard in 1804, he was appointed secretary of the Treasury; and he held the same office under the Duke of Portland (1807-9). In 1814 he became chief Commissioner of the Woods and Forests; in 1823 President of the Board of Trade, and treasurer of the navy; and in 1827 Secretary of State for the Colonies. But he resigned office finally in the following year. Through his exertions the old restrictions on the trade of the colonies with foreign countries were removed. He also obtained the removal or reduction of many import duties, considerable relaxation of the navigation laws, and is allowed to have been an active pioneer of free trade. He received fatal injuries at the opening of the Liverpool and Manchester Railway, 15th September 1830, and died the same evening. A collection of his speeches, with a Life prefixed, was published in 3 vols. in 1831.

Huss, or more properly HUS, JOHN, Bohemian reformer and martyr, was born in (probably) 1369, the son of a Bohemian peasant, at Husinec (of which Hus is a contraction), NW. of Budweis. Two years after taking (1396) his master's degree at the university of Prague he began to lecture there on theological subjects. He had at this time already come under the influence of Wyclif's writings, in all probability through Anne of Bohemia's retinue, and he is believed to have made them the basis of his teaching. In 1402 he was appointed rector of the university, and began to preach at the Bethlehem chapel in the city of Prague. It was not, however, until the year 1408 that he came into conflict with the Roman Catholic Church. In that year certain of his pulpit utterances against clerical abuses were laid hold upon by the clergy of the diocese and city of Prague, and made the ground of a formal complaint against him to the archbishop, Shynko. In consequence of this Huss was forbidden to exercise priestly functions within the diocese. Early in the following year the element of political feeling was infused into the quarrel, all the strong interests of the awakening national consciousness ranging themselves in support of the reformer, who by his preaching had completely won the hearts of the common people. Although Huss was again elected rector of the university in October 1409, the archbishop commissioned an inquisitor to investigate the charges of heretical teaching which had been alleged against him. And it was undoubtedly in connection with this proceeding that in December the pope (Alexander V.) promulgated a bull in condemnation of Wyclif's teaching, and ordered all his writings to be publicly burned, and at the same time forbade preaching in any except collegiate, parish, and monastery churches. This, however, not being sufficient to prevent Huss from continuing his preaching, he was in the following July excommunicated by the Archbishop of Prague. Popular riots followed in the city, and Huss, backed by the

people, still maintained his position; nor did he yield one jot even after the entire city was laid under a papal interdict in 1411. But by the last month of the following year matters had greatly changed, in consequence of Huss having spoken out yet more boldly against the church; hence some of his more influential supporters, including the university, had fallen away from him, so that he was constrained to yield to the desire of the king of Bohemia, Wenceslaus, that he should absent himself from Prague. He found refuge at the castles of certain of his supporters, for nearly the whole body of the nobles were with him. This enforced leisure he employed chiefly in the composition of his principal work, *De Ecclesia*. This book, together with many of Huss's minor writings, contains numerous passages taken almost verbatim from Wyclif's works; and the authorities of the Roman Catholic Church must have looked upon Huss as the expounder and propagator of Wyclif's views. About this time a general council was summoned to meet at Constance, and Huss was called upon to present himself before it, in order to have his case adjudicated upon. Provided with a 'safe conduct' from the Emperor Sigismund, he arrived at Constance on 3d November 1414. Three weeks later, in violation of his safe-conduct, he was seized and thrown into prison. No precise charge had been lodged against him; but he had resumed preaching after his arrival in Constance. An ill-angry for Huss was the condemnation of Wyclif's writings by the council in May 1415. His own trial began on 5th June following; but he was not permitted to speak freely in his own defence, nor allowed to have a defender to speak in his behalf. Called upon to recant unconditionally, to make full submission to the council, and to pledge himself not to preach or teach the doctrines that were put in accusation against him, Huss categorically refused, and was forthwith led to the stake, and burned to ashes, on 6th July.

HUSSITES.—The news of the imprisonment and death of John Huss roused popular feeling in Bohemia to the highest pitch of wrath and indignation. Whilst the masses gave way to rioting and murdered Roman Catholic ecclesiastics, 452 nobles, in a diet which had been hastily summoned at Prague in September 1415, solemnly attested their confidence in Huss, and their admiration of his personal character, and three days later formed themselves into a league for the maintenance of liberty of preaching in Bohemia, and for upholding their belief in the Word of God as the ultimate lawgiver of the church. For this they were excommunicated by the council. Both parties now prepared for war. Yet it soon became apparent that the Hussites were not all of one mind; for, as in all great popular movements of this kind, there was an extreme party who were desirous of carrying things to the greatest lengths. The more moderate section formulated their demands in four articles, preaching of the gospel in the Bohemian language, the right of the laity to receive the communion in both kinds, reform of clerical abuses, and the prohibition of the clergy to hold secular property and exercise secular jurisdiction; these were called Praguerers, but more frequently Calixtines (*calix*—a chalice) or Utraquists (from their claiming communion *sub utraque specie*). The extreme party, headed by Ziska (q.v.), and called Taborites, from their headquarters being at Mount Tabor, some 24 miles N.E. of Pisek, went beyond the Utraquists in their condemnation of purgatory, the worship of saints, of images, and of relics, and the practice of penance, and in their assertion of the right of the laity, even of women, to preach, and that in any building they pleased. At this period too King Wenceslaus died, and the throne of

Bohemia was claimed by his brother, the Emperor Sigismund. Nevertheless, both parties united in offering a stubborn resistance to the emperor, and his forces were defeated at Ziskaberg in 1420, at Deutsch-Brod in 1422, at Aussig in 1426, and at Taus in 1431. Under the two brothers Procopius the Hussites invaded Silesia, Saxony, and Franconia; they were said to have taken and destroyed more than 100 towns and 1500 villages; according to a doubtful legend, Namburg was saved by the intercession of the school children. After the battle of Taus negotiations were begun, which ended, two years later, in the Calixtines securing their ends by the 'Compactata of Prague,' which was signed by the delegate of the Council of Basel on 30th November. This pacification the Taborites refused to accept, and in the contest that then ensued between them and the Calixtines, they were worsted at Lipan near Kolin and at Irib near Bohmisch-Brod in 1434, and from that time rapidly disappear from history. Two years later the Emperor Sigismund, after ratifying the 'Compactata' with his signature, was accepted by the Bohemians as their king. The Utraquists finally became merged in the Moravian Brethren (q.v.).

See *Documenta Johannis Hus citam, doctrinam, causam illustrantia* (ed. by Palacky, 1839), and monographs by Becker (1858), Krummel (1863), Berger (1872), Wratislaw (in English, 1882), and Loserth (1884; Eng. trans. 1884); Doms, *Huss et la Guerre des Hussites* (1878); Palacky, *Urkundliche Beiträge zur Geschichte des Hussitenkriegs* (1872-73); Krummel, *Geschichte der Böhmischem Reformation* (1866); Bezold, *Sagen und die Reichskrieg gegen die Hussiten* (1872-77), and *Zur Geschichte des Hussitenlehrens* (1874); Wratislaw, *John Hus* (1882); Leger, *History of Austro-Hungary* (Eng. trans. 1890); Lechler, *Johannes Huss, ein Lebensbild* (1890); the articles BOHEMIA ('Literature'), ZISKA, PODIEBRAD, CONSTANCE, WYCLIF, &c.

Hussar, a light-cavalry trooper, wearing in full dress a tunic and Busby, (q.v.), and armed with sabre and carbine. The 10th and 18th Light Dragoons were changed in 1806-7 to Hussars, the earliest in the British army (see CAVALRY). The name is not a Hungarian *huszár*, indicating that they were raised one out of every twenty inhabitants; but pure Slavonic for 'Goosherd,' a name given to bodies of wild, raiding horsemen, organised and taken into pay by Matthias Corvinus.

Hussein. See SHITES.

Husum, an old town in the Prussian province of Sleswick-Holstein, 23 miles W. of Sleswick by rail and 2½ from the North Sea. Pop. 6267.

Hutcheson, FRANCIS, a distinguished philosopher of the 18th century, was the son of a Presbyterian minister in the north of Ireland, where he was born in 1694. He studied for the church at the university of Glasgow, but shortly after the completion of his theological course he was induced to open a private academy in the city of Dublin, which proved highly successful. In 1720 he published his *Inquiry into the Original of our Ideas of Beauty and Virtue*, &c., which was the means of introducing him to the notice of many influential personages, such as Lord Granville, then lord lieutenant of Ireland, Archbishop King, Primate Boulter, and others. This work was followed in 1728 by his *Essay on the Nature and Conduct of the Passions*; and in the year after he was appointed professor of Moral Philosophy in the university of Glasgow. Here he died in 1747. In his lifetime he published various minor books, including a small treatise on *Logic*; but his largest work, *A System of Moral Philosophy*, was published at Glasgow in 1755 by his son, Francis Hutcheson, M.D., with a Life by Dr Leechman. As a metaphysician Hutcheson may in some respects be considered a pioneer of the so-called 'Scotch school'

and of the common-sense philosophy, although he is largely influenced by Locke. From the delivery of Hutcheson's lectures, according to Dugald Stewart, may be dated the metaphysical philosophy of Scotland. But it is as a moral philosopher, rather than as a metaphysician, that Hutcheson was conspicuous. His system is to a large extent that of Shaftesbury, but it is more complete, coherent, and clearly illustrated. Hutcheson is a strong opponent of the doctrine that benevolence has a selfish origin; he is practically a utilitarian; and the faculty by which moral distinctions are recognised Hutcheson (after Shaftesbury) terms a *moral sense*. See ETHICS; Fowler, *Shaftesbury and Hutcheson* (1882); and W. R. Scott, *Francis Hutcheson* (1900).

Hutcheson, ANNE, a religious enthusiast, was the daughter of a Lincolnshire clergyman called Marbury. Born in 1590, she married a Mr Hutcheson, and in 1634 they emigrated from Lincolnshire, England, to Boston, Massachusetts. She held various theological heresies; amongst others, that the person of the Holy Ghost dwells in justified persons. She held meetings, lectured, and denounced the Massachusetts clergy as being with few exceptions 'under the covenant of works, not of grace.' Her followers were charged with Antinomianism (q.v.). Great controversies arose, and a synod was called, in which her teachings were condemned; and being tried for heresy and sedition, she was banished from the colony. She and her friends acquired territory from the Narragansett Indians of Rhode Island, where they set up a community on the highly commendable principle that no one was to be 'accounted a delinquent for doctrine.' After the death of her husband (who shared her opinions) she removed to a new settlement in what is now New York state, where, in 1643, she and her whole family of fifteen persons were taken prisoners by the Indians, and all but one daughter barbarously murdered.

Hutcheson, JOHN, an English theological writer, born in 1674 at Spennithorne, in Yorkshire. He was for some time steward of the household of the Duke of Somerset, and left his service to devote himself to his religious studies, the duke procuring for him a sinecure appointment of £200 a year from government. In 1724 he published the first part of a work called *Moses' Principles*, in which he defended what he regarded as the Mosaic cosmogony, and assailed Newton's theory of gravitation. He continued to publish a succession of works till his death, which took place on 28th August 1737. His religious system is best exhibited in his *Thoughts concerning Religion*. The leading principle of it is that the Holy Scriptures contain the elements not only of true religion, but of all rational philosophy, which, however, was to be derived only from the original Hebrew; and it, for that purpose, was subjected to strange critical or rather fanciful processes. His followers were called HUTCHINSONIANS, and among them were persons of considerable learning and celebrity. Ministers of some of the Scottish Presbyterian churches are yet required explicitly to renounce the errors of the Hutchesonians.

Hutcheson, COLONEL JOHN, the type of the Puritan gentleman, was the son of Sir Thomas Hutcheson, and was born at Nottingham in September 1615. He studied at Cambridge, and next for a short time at Lincoln's Inn, and married in 1638 Lucy, daughter of Sir Allen Apsley. He now retired to Owlthorpe, and here his meditations on the troubled theology and politics of the time led him at last to side with the parliament rather than the king. He became governor of Nottingham, and successfully held the town against enemies without and intrigue and calumny from

within till the close of the struggle. About the beginning of the year 1646 he was sent up by Nottingham to fill his father's place in the parliament, and later sat as one of the commissioners in the High Court of Justice for the king's trial, and signed the warrant for his execution. He sat in the first council of state, but gradually became alarmed at the ambitious schemes of Cromwell, and ceased to take an active part in politics. At the Restoration, along with other regicides, he was included in the Act of Amnesty, but later was imprisoned for about a year in the Tower and at Sandown Castle in Kent on a groundless suspicion of treasonable conspiracy, and died 11th September 1664. The *Memoirs*, written by his widowed wife for her children, was first published in 1806, and revealed to the world a delightful picture of a grave and courteous gentleman, beautiful and accomplished; tender to his family and the poor; fearless, frank, and honest in temper; intense in devotion, yet entirely free from austerity and fanaticism. The unsought beauty of the style, and the absolute sincerity and truthfulness of the narrative, give the book an almost unique place among English biographies, and the tender devotedness of loving memory with which throughout it is informed has still power to touch the modern reader with a thrill of sympathetic emotion. An excellent edition, by C. H. Firth, was published in 1885.

Hutten, PHILIP VON, a German adventurer, and a cousin of Ulrich von Hutten, was born at Birkenfeld about the end of the 15th century, and was educated at the court of Henry of Nassau. In 1528 the Emperor Charles V. made a grant of the province of Venezuela to the Welsers, a firm of rich Augsburg merchants; and Hutten sailed with one of the companies they sent out. He accompanied the viceroy, Georg Hoheent, in a long journey (1536-38), in which they reached the headwaters of the Rio Japura, near the equator. In 1541 he set out in search of the Golden City. After several years of wandering, harassed by the natives and weakened by hunger and fever, he and his followers came on a large city, the capital of the Omaguas, in the country north of the Amazons; and attacking this place, they were routed by the Indians, and Hutten himself severely wounded. He led those of his followers who survived back to Coro in 1546, where Juan de Carvajal had in the meantime usurped the office of viceroy; and by him Hutten and his lieutenant, Bartel Welsler, were seized and beheaded. Eight years later the Welsers' grant was taken from them, and the rule of the Germans in Venezuela came to an end. Hutten left a narrative of his journeyings, which was published under the title *Zeitunge uns Indien* (1765). See also Von Langeegg, *El Dorado* (Leip. 1888).

Hutten, ULRICH VON, poet, humanist, and reformer, was born on 21st April 1488, of an old Franconian family whose seat was at Stechelberg, near Fulda. Being piny and small of stature, and of weak health, he was destined, although the eldest son, for the tonsure, and was sent in 1499 to the Benedictine monastery of Fulda. But his temperament—proud, high-spirited, impetuous, impatient of contradiction and of restraint—did not fit him for leading the religious life, and in 1504 or 1505 he fled away from the monastery. Consumed with a devouring hunger for knowledge, especially for the new Humanistic learning, Hutten visited the chief universities of northern Germany, and finally passed by way of Vienna into Italy (1512). During these years he was often utterly destitute, and generally ill, sustained only by his love for the New Learning and his indomitable spirit. His

first works—Latin poems—were printed in 1509; and in the same year he wrote the first of his many bitter satires. From this time onwards his pen never rested; when not employed in behalf of the great cause it was busy in some private feud or quarrel. In Italy Hutten remained nearly two years. On reaching home he was received with distinction at the court of Albert, Archbishop and Elector of Mainz. There he first became acquainted with Erasmus, the leader of the Humanistic movement. In the spring of 1515 all the fiery combativeness of Hutten's nature was roused by the murder of his cousin Hans, who had been wantonly slain by Ulrich, Duke of Wurtemberg. The young poet launched denunciation after denunciation at the guilty duke, and called upon the emperor to punish the offender; and, himself girding the sword upon his thigh, he marched into Wurtemberg along with the army of vengeance his family had raised. His friends then sent him back to Italy to study law. At Rome and at Bologna he spent nearly two years, and came home to enter the service of the Archbishop of Mainz. It was at this time that he wrote his most important work, his share of the *Epistolæ Obscurorum Virorum* (q.v.).

Having been formally crowned poet-laureate of Germany by the Emperor Maximilian at Augsburg in 1517, Hutten began the real work of his life, his deliberate assault upon papal aggressiveness, in an ironical dedication to Leo X. of a new edition of Laurentius Valla's exposure of the fictitious Donation of Constantine. When he first heard of Luther's revolt, Hutten looked upon it as a mere monks' quarrel. In 1519 he took part, along with his subsequent friend and patron, Franz von Sickingen, in the campaign of the Swabian League against his old enemy, Duke Ulrich of Wurtemberg. But this concluded, he returned to the attack upon the papal power. The ideal that possessed his soul was to create a national Germany, delivered from the hateful interference, extortion, and spiritual tyranny of supercilious priests from beyond the Alps. But he also aimed at an intellectual reform of the so-called learned classes, through the spread of the New Learning, and at the cultivation of refinement in the habits and manners of his countrymen. At length he came to understand the real significance of Luther's action, and, at once joining hands with him, he espoused the reformer's part with his customary impetuosity and vehemence. Henceforward he was more closely identified with the Reformation than with the Humanistic movement. A set of dialogues which he published in 1520 contained *Vulsiensis*, his formal manifesto against Rome. This at last stung the pope to take retaliatory measures, and he caused the archbishop to dismiss Hutten from his service. Hutten found shelter in Sickingen's strong castle of Ebernburg in the Palatinate, whence during the next two years he discharged a perfect shower of invectives, denunciations, and satires at the heads of the Romanists, and wrote appeal after appeal to the German emperor, the princes and nobles, bishops, scholars, and people, urging them to shake off the tyrannous domination of the enemies of their country. And in order to get at the common people he began to write in the vernacular, his earliest work in German being *Aufwecker der teutschen Nation* (1520), a poem in which Hutten's satiric powers reach their highest pitch. Sickingen's castle having become unsafe, Hutten fled in 1522 to Basel, where he was greeted with marked coldness by Erasmus. This estrangement shortly afterwards gave rise to a bitter epistolary quarrel. At Basel Hutten was again attacked by the odious disease from which he had suffered since boyhood; and, after seeking

a safe retreat at Mühlhansen and at Zurich, was befriended by Zwingli, who found him an asylum on the little island of Ufnau in the Lake of Zurich. There Hutten ended his stormy life in 1523.

His writings fall into three divisions: (1) Latin poems (1509-16); (2) letters and orations (1515-17); and (3) dialogues and letters, including his German writings (1517-23). See his *Opera Omnia* (7 vols. 1839-62), and lives of him by Strauss (4th ed. 1878; trans. by Sturge, 1874), Schott (1890), and others.

Hutter, LEONHARD, champion of Lutheran orthodoxy, was born in 1563 at Nellingen, near Ulm, and filled the chair of Theology at Wittenberg from 1596 till his death in 1616. His *Compendium* (1610) took the place of Melancthon's *Loci*, and his *Concordia Concordæ* (1614) was long a standard work. His name was adopted by Hase (q.v.) in his well-known rehabilitation of the Old Lutheran dogmatic, *Hutterus Redivivus* (1828; 12th ed. 1883).

Hutton, CHARLES, mathematician, son of a superintendent of mines, was born at Newcastle-upon-Tyne, 14th August 1737; from 1755 to 1773 was a teacher at Jesmond and Newcastle, and published works on arithmetic (1764), mensuration (1771), and bridges (1772). In 1773 he was made professor of Mathematics at the Military Academy, Woolwich, and in 1774 became F.R.S. His calculations for determining the density of the earth from Maskelyne's observations were published in the *Philosophical Transactions* for 1778. He resigned the professorship in 1807; and he died 27th January 1823.

Hutton's most important works are *Tables of Products and Powers of Numbers* (1781), *Mathematical Tables* (1785), *Mathematical and Philosophical Dictionary* (1795), *Course of Mathematics* (1798-1801), and *Recreations in Mathematics and Natural Philosophy* (4 vols. 1803—largely from the French).

Hutton, JAMES, one of the founders of geology, was born at Edinburgh, 3d June 1726. He studied medicine in his native city and at Paris and Leyden, but on his return home (1754) he settled in Berwickshire and devoted himself to agricultural pursuits and to chemistry, from which he was led to mineralogy and geology. In 1768 he removed to Edinburgh, and there spent his time in scientific investigations, and there he died, 26th March 1797. He read two important papers before the Royal Society of Edinburgh, *A Theory of the Earth* (1785; expanded to 2 vols. in 1795) and *A Theory of Rain* (1784). The upraised land of the globe must, he thought, be worn away by atmospheric influences, and the debris be finally deposited in the bed of the sea, where they are consolidated under great pressure; they are then forced upwards by subterranean heat acting with an expansive power, and thereby split and cracked, the fissures at the same time filling with molten mineral matter; and so the process goes on. The formation of rain he ascribed to the mingling of two strata of air of different temperatures and the subsequent condensation of the mixture.

He also wrote *Dissertations in Natural Philosophy* (1792), *Considerations on the Nature of Coal and Calm* (1777), and other works. See GEOLOGY.

Hutton, RICHARD HOLT, son and grandson of Unitarian ministers, was born at Leeds in 1826, studied at University College and School, London, and under Martineau at the Manchester New College. He was for some time a Unitarian preacher, became principal of University Hall, and contributed to Unitarian periodicals. Under the influence of F. D. Maurice he joined the Church of England, edited the new quarterly *National Review*, and taught mathematics in Bedford College. About 1860 he and Mr Townsend became associated as joint editors of the *Spectator* (founded in 1828), to which he gave the impress of his accomplished,

resolute, devout mind. He revered Cardinal Newman; had constant regard to ethical and religious interests in his judgments of men and movements, whether literary, social, or political; and greatly strengthened opposition to Irish Home Rule. His *Studies in Parliament* (1866), *Essays, Theological and Literary* (1871; new ed. 1880), and *Modern Guides of English Thought* (1887) were republished from the periodicals; his monograph on Scott ('Men of Letters,' 1878) was his least effective publication. His last years were clouded by the melancholia of his second wife, who, like his first, belonged to the Liverpool Roseoe family. He died 11th September 1897.

Huxley, THOMAS HENRY, biologist, born at Ealing, Middlesex, 4th May 1825, commenced his education at the school in that place, then a small village, and afterwards studied medicine in the Medical School of Charing Cross Hospital. In 1846 he entered the medical service of the royal navy, and did duty at Haslar, until the winter of the same year, under the late Sir John Richardson, by whose influence he was appointed assistant-surgeon of H.M.S. *Rattlesnake*. This vessel, commanded by Captain Owen Stanley, was commissioned to survey the intricate passage within the Barrier Reef skirting the eastern shores of Australia, and to explore the sea lying between the northern end of that reef and New Guinea. Huxley devoted himself with zeal to the study of the numerous marine animals collected during the survey, and made them the subjects of scientific papers, which were published by the Royal and Linnean societies. Towards the end of 1850 the *Rattlesnake* returned to England, and Huxley had the gratification to find that his paper *On the Anatomy and Affinities of the Family of the Medusa* had been published in the *Philosophical Transactions*. In 1851 Huxley was elected a Fellow of the Royal Society; in 1852 one of the two Royal medals annually given by the Society was awarded to him; and in 1853 he contributed to the Society's *Transactions* a memoir on the morphology of the Cephalous Mollusca. In 1854 he was appointed professor of Natural History, including Palaeontology, in the Royal School of Mines in place of Professor Edward Forbes, and held that office, combined with the curatorship of the fossil collections in the Museum of Practical Geology, until his retirement from the public service in 1885. It was part of the duty of the professor to deliver a course of six lectures to working-men every alternate year. Some of these have been published. In 1854 he published contributions to the anatomy of the *Brachiopoda*, in which some hitherto unsuspected peculiarities of their structure were described; and in this and the preceding year he wrote several essays on histological subjects. In 1856 he accompanied his friend Dr Tyndall in his first visit to the glaciers of the Alps, and his name appears as joint-author of a paper, *Observations on Glaciers* (*Phil. Trans.* 1857). In 1859 his large work on *The Oceanic Hydrozoa; a Description of the Calyptrophorida and Physophorida* observed during his voyage, was published by the Ray Society with illustrative plates. After his appointment to the Royal School of Mines, Huxley's attention was chiefly directed to vertebrate morphology and to palaeontology, with occasional excursions into the region of ethnology; but papers on the agamic reproduction and morphology of *Aphis* (1858), on the development of *Pycnosoma* (1860), a manual of the Invertebrata (1877), and classification and distribution of Crayfishes (1878) are evidence that the Invertebrata were not neglected. In vertebrate morphology the most important papers are the Royal Society's Croonian lecture, *On the Theory of the Vertebrate Skull* (1858); various papers on the

brain in man and apes, and on the relation of man to the lower animals, and *Man's Place in Nature* (1860-63); on the classification of Birds, and on the *Dinosauria* (1868-70); the article 'Amphibia' in *Ency. Britannica* (1875); *On Ceratodus* (1876); the cranial and dental structure of the *Cauder* (1880); *Lectures on Comparative Anatomy* (1864); *An Introduction to the Classification of Animals* (1869). In palaeontology, besides various papers on other fossil Invertebrata, memoirs on *Pterogotus* (1858) and *Belonites* (1864); a series of papers on *Staganolepis Robertsoni* and *Hyperolopetodon Gordonii* (1859-77-87); preliminary essay and descriptions of Fossil Fishes in the Decades of the Geological Survey (1862); *Glyptodon* (1863); Neanderthal Skull (1864); Reptilian Remains from India (1864); *Tetrapetodon* (1866); Amphibia from the Kilkenny Coal-measures (1867-71); *Hypsilophodon* and Evidences of Affinity between Reptiles and Birds (1869-70); *Chelonia* from Lord Howe Island (1887). In physiology, a short treatise, *Lessons in Elementary Physiology*. Essays on topics of a philosophical and general character are collected in *Lay Sermons*, &c. (1870); *Critiques and Addresses* (1873); *American Addresses and Physiography* (1877); a short work on *Haem* (1879); *Science and Culture* (1881); and *Science and Hebrew Tradition* (1894). His collected essays, with an autobiography, were issued in 9 volumes in 1893-95. A member of the Privy Council since 1892, he died at Eastbourne, 29th June 1895. His son Leonard wrote his *Life and Letters* (2 vols. 1900).

Huxley strongly advocated and greatly furthered Darwin's views and evolutionist doctrines in general, and was a keen and incisive critic of what he regarded as obscurantist theological prejudices. He held the offices of examiner in the university of London, of Fullerian professor at the Royal Institution, of Hunterian professor of Comparative Anatomy at the Royal College of Surgeons, of president of the Ethnological Society and of the British Association. He was secretary and president of the Geological Society, and secretary and president of the Royal Society. He was elected in 1873 Lord Rector of the university of Aberdeen, and a member of the London School Board in 1870. He was an active member of the Royal Commission on Sea-fisheries (1864-66), and served on several other commissions; and he was inspector of Salmon-fisheries from 1881 to 1885. He received the Wollaston medal, the Copley medal, and a Swedish order. Honorary degrees were conferred on him by Oxford, Cambridge, Würzburg, Brussels, Bologna, Breslau, Edinburgh, and Dublin. He was a foreign or corresponding member of the American, Brussels, Berlin, and French academies.

Huy, a town of Belgium, is romantically situated amid lofty rocks on both banks of the Meuse, 19 miles SW. of Liège by rail. Its citadel (1822), whose works are partly excavated in the solid rock, commands the passage of the river. The church of Notre Dame, a graceful Gothic edifice, was begun in 1311. In the vicinity are iron-works and coal-mines, and the manufactures include paper, leather, beer, spirits, &c. Pop. (1876) 11,774; (1890) 14,486. Peter the Hermit founded here the former Abbey of Nonfontier (*Noëum Monasterium*), and here in 1115 he died. Huy has been frequently besieged.

Huygens, CHRISTIAN, one of the great philosophers of the 17th century, was born at the Hague, April 14, 1629, and was the second son of Constantine Huygens, poet, diplomatist, and secretary to the Prince of Orange, who was knighted by James I. of England in 1622. Huygens studied at Leyden and Breda. His first work, *Theorematum de Quadratura Hyperbolæ, Ellipsis, et Circuli* (1651),

is an example of that powerful geometrical talent which lay at the foundation of all his scientific achievements. Soon after this he constructed the pendulum-clock, following out the idea first suggested by Galileo (see *HOROLOGY*). A complete description of Huygens' instrument is contained in his great work, *Horologium Oscillatorium* (1673). This work contains expositions of many of the cases of constrained motion, especially those applicable to the construction of timekeepers. Huygens also developed and gave precision to the investigations of Galileo upon accelerated motion under the action of gravity; and there is no doubt that to the clearness of his demonstrations his great successor, Newton, in preparing his magnificent development of the principle of accelerating force, was largely indebted. Newton was a student and admirer of his works, and assigns to him, along with Sir C. Wren and Wallis, the distinguished epithet of *hujus ætatis geometrarum favile principes*. By means of an improved telescope of his own construction, Huygens in 1655 discovered the ring of Saturn and the fourth satellite of that planet. In 1659 he published an account of these discoveries in a work entitled *Systema Saturnium*. In the end of this work the Micrometer (q.v.) is described. In 1660 Huygens visited England, where he was admitted a member of the Royal Society. He discovered the laws of collision of elastic bodies about the same time as Wallis and Wren, and also made a material improvement in the air-pump. But his most important discoveries are in the department of optics: he it was who first propounded and developed what is now known as the undulatory theory of Light (q.v.), and he is the discoverer of Polarisation (q.v.). The 'principle of Huygens' is a part of the wave-theory. In 1666 Huygens received an invitation to settle in France, with the promise of a pension from Colbert, then all-powerful in that country. At Paris he remained till 1681, a member of the Royal Academy of Sciences; but alarmed at the danger which seemed impending over the Protestants, he returned to his own country, and died at the Hague, 8th July 1693. His *Œuvres Complètes* have been issued since 1888 by the Amsterdam Academy of Sciences.

Huysmans, JORIS KARL, novelist, was born the son of a Dutch father at Paris 5th February 1848, and since 1866 holds a post in the French ministry of the interior. His first novel, *See au Dux* (1872), was followed by a series, all full of Zola's realism, till in 1895, when his works began to breathe a spirit of Catholic mysticism.

Huysum, JAN VAN (1682-1749), Dutch painter, was born and died at Amsterdam. His landscapes are conventional and artificial, but his fruit and flower pieces are exquisite.

Huzvaresh, the non-Iranian element in the Pehlvi dialect. See ZEND.

Hwen-tsang, or HUCEN-TSANG, a Buddhist monk of China, who was born near Honan about 605, and who in 629 set out on a pilgrimage to India, travelling by way of the Desert of Gobi, Tashkend, Samarcand, Bamian (q.v.), and Peshawar. He remained in India a period of thirteen years (631-44), visiting the sacred places connected with his religion, and studying its sacred books. He died in 664 in a convent at Chang-ngan (now Singan). Owing to the many curious notices he gives of matters which came under his observation, and the high degree of trustworthiness which his narrative possesses, his memoirs are regarded as one of the most important works on the history of India in general, and of Buddhism in particular, during the period stated. The account of his travels was written, not by himself, but under his supervision, and was completed in 618. According

to a remark added to the title in the imperial Chinese edition, the work would seem to have been translated from Sanskrit into Chinese; but this can only mean, as Stanislas Julien observes, that the fundamental part of the work relating to history, legends, &c., was taken from Hindu sources. Besides this book, there exists a biography of Hwen-Tsang written by two of his disciples. Both works were translated into French by Stanislas Julien (Paris, 1853 and 1857-58), and an abstract of these by H. H. Wilson appeared in the 17th volume of the *Journal of the Royal Asiatic Society*. See also *Hien Tsüing* in Trübner's Oriental Library (1888).

Hyacinth (*Hyacinthus*), a genus of plants of the natural order Liliaceæ; bulbous-rooted plants with corolla-like, bell-shaped, 6-cleft perianth, six stamens fixed in the tube of the perianth, and dry capsular fruit. The flower was fabled to have sprung from the blood of the beautiful Spartan Hyacinthus, beloved of Apollo and Zephyrus. Zephyrus, jealous because Hyacinthus favoured Apollo, caused Apollo's quoit to strike and slay the beautiful youth while the two were at play.—The Oriental Hyacinth (*H. orientalis*), one of the most favourite of florists' flowers, is a native of Asia Minor, Syria, and Persia. It is now naturalised in some parts of the south of Europe. It has broad linear leaves, and a scape with a raceme of many flowers pointing in all directions. The flowers in cultivation exhibit great variety of colour, chiefly blue, purple, and white. They are very beautiful and very fragrant. The fragrance is strongest about or after eleven o'clock at night. Among cultivated hyacinths are many with double flowers.

The hyacinth has been cultivated from a remote period. It was introduced into Europe, probably by the Dutch, about the beginning of the 16th century, soon after the revival of commerce, when the traders of Holland carried their merchandise to the eastern shores of the Mediterranean and the Archipelago. It was very little known in Britain till towards the beginning of the 17th century, but soon after its cultivation had become a passion with the wealthy, as it had for some time been with the Dutch. Extravagant prices—as much as £200—were paid for a single bulb of varieties having special or rare merits. This passion declined towards the middle of the 18th century, and the cultivation of the hyacinth became very much depressed. In recent years, however, it has been very much extended, and forms one of the principal industries of florists around Haarlem, which is and always has been the centre of the Dutch bulb trade; but their efforts are now directed with the view of meeting the demand of the million rather than the special requirements of the fanciful wealthy few. Hyacinth bulbs, planted in pots, readily produce beautiful flowers; and flowers almost equally beautiful are obtained for one year only, however, by placing them in water in hyacinth-glasses, in which they form a favourite ornament of apartments in winter and early spring. The cultivation of hyacinths in the open ground

Hyacinth
(*Hyacinthus orientalis*).

is much more difficult, their early growth being liable to be destroyed by adverse weather. New varieties are raised from seed. Several other species of hyacinths are natives of the south of Europe, Africa, &c.—The Grape-hyacinth and Globe-hyacinth, frequently cultivated as garden flowers, are now referred to the genus *Muscari*.—A common British plant, growing in woods and copses, with beautiful blue flowers very like those of the oriental hyacinth, but all drooping to one side (*H. non-scriptas*, also known as *Scilla nutans*, *Eudymion nutans*, and *Agraphis nutans*), is sometimes called the Wild Hyacinth, and sometimes the Blue-bell (q.v.). The bulbs have been used for making starch.—The name hyacinth is also given to varieties of garnet, topaz, sapphire, and zircon.

Hyacinthe, PERE, is the former monastic name of CHARLES LOYSON, born at Orleans, 10th March 1827. He studied at St Sulpice, and in 1851 becoming priest, taught philosophy and theology at Avignon and Nantes. Subsequently entering the order of the Carmelites, he became known as a powerful preacher, and gathered crowded and enthusiastic audiences of all ranks of society to the Madeleine and Notre Dame in Paris. Almost as remarkable as his eloquence was the boldness with which he denounced existing abuses in the church; and Archbishop Darboy defended him against the accusations of the Jesuits till in 1869 the General of his order imposed silence on him. Hyacinthe replied by a letter in which he called for a thorough reform of the church, and was excommunicated. Relieved from monastic vows by the pope, he became a secular priest under the name of the Abbe Loyson. He protested vigorously against the Infallibility Dogma; but although he attended the 'Old Catholic' Congress at Munich, and on visits to the United States and England fraternised with Protestants, he always declared his intention to remain in the Catholic Church, trying to obtain reforms, such as the liberty of marriage for the clergy. In 1872 he married an American lady. In 1873 he was chosen curé of a congregation of Liberal Catholics at Geneva, but soon left them. He has published sermons and lectures, and in 1879 established a 'Gallican' congregation in Paris, which in 1884 attached itself to the Old Catholic Church in Holland.

Hyades, in Greek Mythology, the nurses and guardians (3, 5, or 7 in number) of young Dionysus. Zeus converted them into stars and transplanted them to the heavens, where they form the head of the constellation Taurus. Their rising with the sun was held in Greece to mark the beginning of the rainy season.

Hyæna, a genus of digitigrade carnivorous quadrupeds, included in the genus *Canis* by Linnaeus, but now referred to the Elmoïd division of the Carnivora, of which, however, it is a somewhat aberrant member, forming with *Proteles* (q.v.) a sub-family, Hyænina. Hyænas have six incisors and two canine teeth in each jaw, five molars on each side in the upper jaw, and four in the under. They seize an object with so firm a hold that, among the Arabs, they are proverbial for obstinacy. The vertebrae of the neck sometimes become ankylosed in old hyænas. The hind-quarters are lower and weaker than the fore-quarters of the body, so that hyænas move with a shuffling gait. The body is covered with rather long coarse hair, forming a mane along the neck and back. The feet have each four toes. The claws are strong, fit for digging, and not retractile. The tail is rather short. Beneath the anus is a deep glandular pouch, contributing much to the offensive odour by which hyænas are characterised. Hyænas eat carrion, as well as newly-killed prey, and are of much use, like

vultures, as scavengers, clearing away the last remnants of carcasses that if left to rot would greatly pollute the air. They sometimes attack cattle, especially if they flee, but rarely man, though they sometimes seize children. During the day they hide themselves in caves, old rock-tombs, ruined edifices, &c.; by night they roam singly or in packs in quest of prey. They prowl about towns and villages, and often dig up corpses that have not been very deeply buried. This, together with their aspect and manners, has caused them to be generally regarded with horror, and very exaggerated accounts of their fierceness have been prevalent. Instead of being untaimable, as was long the popular belief, they are capable of being very completely tamed, and show an attachment to man similar to that of the dog; they have even been used as watch-dogs. Hyænas are found only in Africa and the south of Asia, not extending to the furthest east of the latter continent.—The Striped Hyæna (*H. strata*) is found both in Asia and Africa, and there are several varieties considerably different in size, colour, &c. The smallest hyænas are of the size of a large dog. The Spotted Hyæna (*H. crocuta*) inhabits South Africa. It is rather smaller than the largest varieties of the striped hyæna, but is more fierce and dangerous. It is called Tiger-wolf by the colonists of the Cape of Good Hope.

Spotted Hyæna (*Hyæna crocuta*).

Besides its ordinary howling, which it emits very freely in its nocturnal roamings, this hyæna often indulges in an expression of gratification or of some passion, resembling hysterical laughter, whence it has acquired the name of the Laughing Hyæna. The general colour is ochry gray, with thinly scattered small round brown spots, and sooty muzzle and feet. The Woolly Hyæna (*H. brunnea*) is a smaller South African species.

In consequence of the bones which hyænas eat, their dung forms solid yellowish-white balls, of compact earthy fracture, the *Album graecum* of the old materia medica. For the Hyæna Dog, see Dog.

Hyæ-hyæ. See COW-TREE.

Hybla, the name of three cities of ancient Sicily. (1) An old Sicilian town situated on the southern slope of Mount Etna, which figured in the second Punic war; its site is fixed at the modern Paterno.—(2) A city founded by the Megarians about 726 B.C., and probably identified with the city called Megara. It was destroyed by Gelon of Syracuse in 481 B.C. It is believed to have stood near the modern Agosta.—(3) A third Hybla lay between Syracuse and Agrigento. The Hyblæan honey, so much sung by Latin poets, was gathered on the hills near the first two cities.

Hybrid (Gr. *hybris*, 'lust'), the offspring of two parents which belong to different varieties, or to different species, or even to different genera. Thus, according to the degree of divergence

between the parents, variety-hybrids, or mongrels, species-hybrids (the usual application of the term), and genus-hybrids, which are very rare, have to be distinguished. It is also useful to note with Broca that hybridisation may be (a) *natural*—i.e. occurring in undisturbed natural conditions, of which we know relatively few cases; (b) *incited*—i.e. under direct human control, on which our data as regards animals are chiefly based; and (c) *artificial*—i.e. by placing the pollen of one plant on the stigma of another species, or by mixing with the eggs of some animal, say frog or fish, the male elements of some related form.

Among mammals genus-hybrids find illustration in the successful crossing of he-goat (*Capra*) and ewe (*Ovis*), the offspring being fertile for several generations, both *inter se* and with the parent-stocks. Species-hybrids are well illustrated in the results of crossing various members of the genus *Equus*—e.g. male ass and mare, the offspring being a mule; or horse and female ass, the offspring being a hinny. Similarly, dog and fox, dog and jackal, lion and tiger, hare and rabbit, Indian lumped cattle and our very different domesticated breeds, and not a few other more or less nearly related forms have been successfully crossed. For such names as 'leopard,' which suggest that crossing occurs or occurred somewhat freely in nature, there is little or no evidence. Nor was there any truth in the supposition that 'Jumarts' resulted from the crossing of bull and mare, or stallion and cow, for Jumarts turn out to have been nothing more than hinnies.

Among birds the common duck (*Anas boschas*) and a pintail (*Dafila acuta*), the common goose (*Anser ferus*) and the very distinct Chinese goose (*A. cygnoides*), goose and swan, canaries and finches, pheasant and hen, and other allied forms are recorded as giving rise to hybrids. Among lower animals hybrids also occur; different species of toad are often seen in sexual union, but the result is unknown; the artificial fertilisation of frog ova with the sperms of other species has at least resulted in the development of hybrid tadpoles; in several fishes hybridisation seems to occur in natural conditions, and artificial fertilisation has been effected even between genera, to the extent at any rate of starting the development of the ova. The hybrids of two moths (*Bombyx cyathia* and *B. arctiada*) have been recorded as fertile *inter se* for eight generations; and R. Hertwig has shown that in certain conditions the male elements of one species of Echinoderm may incite development in the ova of another.

Hybridisation in Plants. Experiment is here much easier, and a large mass of data has rewarded the investigations of Kohreuter (1761), Andrew Knight, Dean Herbert, Gartner, Wichura, Hildebrand, Focke, and others. The subject received careful disquisition from Darwin in his work on cross fertilisation, and also from Nageli, a summary of whose conclusions is available in the English translation of Sachs's *Text-book of Botany*. Only the leading results can be noted here. Hybridisation rarely occurs except between forms known to be related; variety-hybrids occur easily and abundantly; species-hybrids are less, though quite common; genus-hybrids (e.g. between the grasses, *Egilops* and *Triticum*, between *Rhododendron* and *Azalea*, between *Lycnis* and *Silene*) are rare. Besides genetic relationship, some subtle harmony, which we can only call 'sexual affinity,' is essential to successful hybridisation. When one species can be fertilised by the pollen of another, the *vice versa* relation usually holds good; but sometimes the hybridisation is persistently one-sided. Kohreuter easily obtained seeds from *Micaulis jalapa* with the pollen of *M. longiflora*, while more than two hundred experiments, extending

over eight years, with the pollen of the former upon the stigma of the latter were futile. The results of hybrid fertilisation exhibit many degrees; thus, the mother-plant may be affected by the strange pollen without seeds being produced, or seeds may be formed which will not germinate, or numerous, vigorous, and fertile hybrids may result. When two kinds of pollen are simultaneously applied to the stigma only one kind is potent. The hybrid is usually intermediate between the two parents, not only in structural features, such as the venation of the leaves and the shape of the flower, but in physiological peculiarities, such as the time of flowering and the mode of coloration. Focke reports a curious case where the crossing of *Anagallis carrollae*

Hybrid Leaves:

A, leaf of *Salix caprea*; B, of *S. viminalis*; C, of hybrid between these two species. (After Wichura.)

and *A. phoenicea* produced hybrids which bore in part the blue flowers of the former species, and in part the reddish flowers of the latter. Hybrids are usually more variable than the parents, and the variation may be towards strength or towards weakness. Since Fairchild, at the beginning of the 18th century, first intentionally produced a cross between *Dianthus barbatus* and *D. caryophyllus*, hybridisation has often been resorted to by gardeners and arboriculturists to produce a strong stock. Very important are the numerous hybrids between European and American vines, some of which are believed to be endowed with greater powers of resisting Phylloxera and fungi than the unaltered European plants possess. There can be no doubt that species-hybrids among plants tend to be sterile, and this the more the wider the difference between the parent plants. Sometimes three or even six individualities have been gradually mingled in a multiple hybrid, and this lessens still more the chance of fertility.

Character of Hybrids.—The products of crossing, whether of species or of varieties, are undoubtedly very variable, sometimes for the better as in many of our domesticated mongrels among both animals and plants—very often on the other hand for the worse. They are often so unstable that they tend rapidly to die out, as has been observed among some human experiments in mingling races. The saying 'God made the white man, God made the black man, the devil made the mulatto,' expresses a feeling as to the frequently inconvenient variability of variety-hybrids, but there is much to be said on the other side. Such a case as sheep-goat hybrids shows how far from accurate is the still prevalent belief that hybrids from widely separated parent forms must be sterile. We are by no means warranted in saying more than that species-hybrids tend to be sterile so far as we

know them, and that it must be remembered is for the most part in conditions of domestication, where the resulting sterility may have been due to confinement, and to prolonged interbreeding, rather than to the hybridisation itself. Nor do the facts allow us to accept the further generalisation that variety-hybrids are always fertile. Not only are there cases of the reverse, but, as Wallace justly points out, the conclusion was again based on domesticated forms, in regard to which it must be noted that the very first essential to their becoming domesticated was that they should continue fertile under changed conditions of life.

Hybrids in Relation to Evolution.—The facts of hybridism raise some of the most intricate problems connected with evolution. As only a few general statements can be noted here, the reader is referred to the cited work of Alfred Russel Wallace. (1) Fertility or non-fertility of crosses must not be exaggerated into the test between variety and species, for all species-hybrids are not sterile, nor all variety-hybrids fertile. (2) Fertility depends on some delicate mutual adjustment or complementariness of the male and female elements, and is readily disturbed by external or constitutional conditions. (3) Animals seem to prefer to breed with their like among existing varieties, and in this way it is believed that the 'swamping effects of intercrossing' have been usually obviated, though mutual infertility and geographical separation may also assist in preserving the varieties. (4) Brooks has laid stress upon the fact that both variety and species hybrids are highly variable. In his theory of 'physiological selection,' Romanes has emphasised the importance of mutual sterility in splitting up one species into several. 'Whenever any variation in the highly variable reproductive system occurs, tending to sterility with the parent form without impairing fertility with the varietal form, a physiological barrier must interpose, dividing the species into two parts, free to develop distinct histories, without mutual intercrossing, or by independent variation.' (5) Darwin concluded that 'the sterility or infertility of species with each other, whether manifested in the difficulty of obtaining first crosses between them, or in the sterility of the hybrids thus obtained, was not a constant or necessary result of specific difference, but is incidental on unknown peculiarities of the reproductive system.' Wallace has advanced a step further in his endeavour to show that 'if we accept the association of some degree of infertility, however slight, as a not unfrequent accompaniment of the external differences which always arise in a state of nature between varieties and incipient species, natural selection has the power to increase that infertility just as it has the power to increase other favourable variations.'

Hydaspes. See JHELUM.

Hydatid (from the Greek *hydatis*, 'a watery vesicle'), a term applied to the bladder-worm (*scælaræ*) stage of certain tapeworms, but particularly to that of *Tænia echinococcus*, found especially in

man and monkeys, ox and swine, in liver, lungs, or almost any organ. The bladder-worm (*Echinococcus cerebrorum*) is often very conspicuous, from the size of a pea to that of a child's head, weighing in some cases 12 to 30 lb., and notable among bladder-worms for its prolific asexual multiplication. From the inner surface, in numerous special brood-capsules of the size of millet-seed, sometimes hundreds of 'heads' are huddled off; while daughter-bladders may also be produced externally.

The adult tape-worm is small, and lives socially in the intestines of dog, jackal, or

A, brood-capsule of *Echinococcus cerebrorum*, with fully-formed and rudimentary heads; B, adult *Tænia echinococcus*.

wolf. It is from the dog being kept too much about the house or person that the eggs which give rise to the dreadful *Echinococcus* find their way to man. The disease is known in most countries of Europe, but is commonest in Iceland. The term hydatid is sometimes extended to other bladder-worms—e.g. the 'stagger-worm' (*T. caninus*) of the sheep, or in medicine to serous cysts which have nothing at all to do with parasites. See TAPEWORM; and for a very full discussion of *Echinococcus*, see Lenekart's *Parasites of Man* (trans. by W. E. Hoyle, vol. i. Edin. 1886).

Hyde, an important manufacturing town of Cheshire, 7 miles ESE. of Manchester, and 5 NE. of Stockport. Standing in a coalfield, and enjoying ample facilities of communication by road, rail, and canal, it has risen from a mere village to a considerable town, which in 1881 was incorporated as a municipal borough. Cotton is of course the staple manufacture; then come the felt-hat industry, engineering, boiler-making, &c. The town-hall is a handsome building. Pop. (1811) 1806; (1861) 13,722; (1891) 30,670.

Hyde, EDWARD. See CLARENDON (EARL OF).

Hyderabad (*Haidarabad*), or the NIZAM'S DOMINIONS, a great native or feudatory state of India, occupies the greater part of the Deccan proper or central plateau of southern India, between the provinces of Madras and Bombay. Area, 81,807 sq. m. (excluding the British assigned districts of Berar, q.v.); pop. (1881) 9,845,594; (1891) 11,537,040. About a tenth only are Mohammedans, found mainly in the capital, though the Nizam and state are Mohammedan. Telugu, Kanarese, and Marathi are the principal languages spoken. Education is making rapid strides; during the three years previous to 1889 the number of schools nearly doubled, and the pupils increased from 11,740 to 27,700. The surface is a slightly-elevated tableland. The principal rivers are the Godavari, with its tributaries the Dudna, Manjira, and Pranrita; and the Kistna (Krishna), with its tributaries the Bhima and Tungabhadra. The soil is in general very fertile, but poorly cultivated; yet, wherever it receives moderate attention, it yields harvests all the year round. The products are rice, wheat, maize, mustard, castor-oil, sugar cane, cotton, indigo, fruits (including grapes and melons), and all kinds of kitchen vegetables. The pasturages are extensive, and sheep and horned cattle are numerous. The climate is good on the whole.

The mean temperature of the capital, Hyderabad, in January is 74° 30', and in May 93°. The exports are cotton, oil-seeds, cloth, hides, metal wares, and agricultural produce; salt, grain, timber, European piece-goods, and hardware are imported. The railway from Madras to Bombay intersects the south-west part of the state. The state revenue is about £4,000,000 a year; and there is an army of 13,000 infantry and 1400 cavalry, besides a large force of irregulars (possibly some 48,000 constitute the military force).

In 1687 the territory long known as the Nizam's Dominions became a province of the Mogul empire; but soon after 1713 the governor or viceroy of the Deccan, Asaf Jah, with the title of *Nizam-ul-Mulk* ('regulator of the state'), made himself independent. After his death, in 1748, two claimants appeared for the throne, his son Nasir Jang, and his grandson Muzaffar Jang. The cause of the former was espoused by the East India Company, and that of the latter by a body of French adventurers under General Dupleix. Then followed a period of strife and anarchy. In 1761 Nizam Ali obtained the supreme power, and after some vacillation signed a treaty of alliance with the English in 1766. He aided them in the war with Tippoo, sultan of Mysore, and at the termination of that war, in 1799, a new treaty was formed, by which, in return for certain territorial concessions, the East India Company bound itself to maintain a subsidiary force of 6000 men for the defence of the Nizam's dominions. Another treaty was concluded in 1853. The Nizam, who in point of rank is the first Mohammedan ruler in India, remained faithful to the British during the mutiny of 1857-58 (see JUNG, SIR SALAB). The assigned districts (see BEGAR) were in 1861 given in trust to Britain on account of unpaid and increasing debts; the surplus revenue being returned to the Nizam.

Hyderabad (*Haiderabad*), the capital of Hyderabad state, stands on the right bank of the Musi, at an elevation of 1700 feet above the sea, by rail 390 miles N.W. of Madras. It is 6 miles in circumference, and is surrounded by a stone wall, flanked by bastions. In 1891 the population, inclusive of the suburbs, was 415,039. The populace consists of very varied elements, and is full of war-like spirit, nearly every one carrying weapons. The street architecture is uninteresting. The palace of the Nizam, though architecturally of no great importance, is of vast size. Hyderabad is one of the most important strongholds of Mohammedanism in India, and the mosques are numerous. The principal mosque was fashioned after the model of the Great Mosque at Mecca; in the interior are fine monolithic granite columns, and outside the building is crowned by very lofty minarets. Another remarkable edifice is the Char Minar or College, with four minarets resting on four connected arches, at which the four principal thoroughfares converge. On the opposite side of the river is the British Residency, a magnificent pile, with the finest staircase in India; it stands in the midst of fine ornamental gardens, and communicates with the Nizam's palace by a bridge with eight spacious arches of squared granite. The neighbourhood boasts of wild and picturesque scenery, and abounds with huge tanks and beautiful gardens. Secunderabad (*Sikandarabad*) is a British military cantonment (pop. 1881, 74,124) 6 miles N.E. of Hyderabad.

Hyderabad, the historical capital of Sind, and chief city of a district, stands 32 miles E. of the left bank of the Indus. Pop. (1891) 58,048, of whom 25,000 were Mohammedans. The town is the main centre of postal, telegraphic, and road communication for the province, though the Sind railway, terminating at Kurachee, is on the other

side of the Indus. It is famous for the manufacture of silks, gold-work, pottery, lacquered ware, and arms of various kinds. There is now a plentiful water-supply from the Indus. As against a native force it is tolerably strong, occupying a somewhat steep height, and having a rampart flanked by round towers.

Hyder Ali (*Haider Ali*), ruler of Mysore, and one of the greatest Mohammedan princes of India, was born in 1728. His grandfather was a wandering fakir; his father a constable of a district in Mysore. Hyder spent his youth in idleness, though occasionally doing military service; but in 1749 his bravery at a siege attracted the notice of the maharajah of Mysore's minister. He soon became in all but name ruler of the kingdom; and in 1759 he dispossessed his master, allowing him to retain his title, while he himself took that of *dawra*, or regent. He then conquered Calicut, Bednor, Kanamur, and other neighbouring states; and in 1766 his dominions included more than 84,000 sq. m. He withheld the customary tribute from the Mahrattas (q.v.), and carried on an ultimately successful war against them. He waged two wars against the British, in the first of which (1767-69) he was practically successful, and signed a treaty under the walls of Madras, which provided for a kind of alliance. When Hyder was defeated by the Mahrattas in 1772 he claimed English support; and on the refusal of the Madras government to fulfil what he believed to be the treaty obligations, he became the bitter enemy of the English. Taking advantage of the war between the English and French (1778), he and his son and successor, Tippoo Saib, descended like a thunderbolt into the Carnatic, totally routed two English commanders, and ravaged the country to within forty miles of Madras; but he was ultimately defeated in three battles by Sir Eyre Coote. He died suddenly, still in alliance with the French, in December 1782. See L. B. Bowring, *Haider Ali and Tippu Sultan* (1893).

Hydnora, a genus of parasitic plants belonging to the order Cytinaceae, which consists entirely of root-parasites. *Hydnora africana* is a South African species parasitic on the roots of fleshy Euphorbiac and other succulent plants; it has a putrid smell, but is roasted and eaten by the natives, and is also used for tanning.

Hydnum, a genus of fungi belonging to the sub-order Hymenomyces, order Basidiomycetes, and having the under side of the *pileus* covered with soft spines which bear the spores. The species are numerous, some of them British; among these is *H. repandum*, more common in some parts of the continent of Europe, and much used as an esculent in France, Italy, and Germany. It grows chiefly in pine and oak woods.

Hydra, a Greek island, lies 4 miles from the coast of the Peloponnesian department of Argolis and Corinth. It is a narrow rocky ridge, 11 miles long, 1960 feet high, and 20 sq. m. in area. The shores are rocky and steep, and the interior is destitute of vegetation and of water. On the north-west coast is the seaport of Hydra (6446). The 7342 islanders, mostly of Albanian origin, make excellent seamen, and carry on cotton and silk weaving, tanning, shipbuilding, sponge-fishing, and commerce. The island was uninhabited in ancient times. Previous to the war of Greek independence the Hydriotes numbered more than 28,000, and were considered the richest people in the archipelago. They enjoyed a large share of the carrying-trade in the Black Sea and the Mediterranean, and traded to England, the Baltic, and even America. In the war they took a most active and conspicuous part; but on the restoration

of peace the island lost much of its former prosperity, being outrivalled by Syra.

Hydra, a fabulous monster of the ancient world, said to have inhabited the marshes of Lernæa, in Argolis, not far from the sea-coast. Accounts vary both as to its origin and appearance. Some make it the issue of Styx and the Titan Pallas, and others, of Echidna and Typhon. It is represented as having several heads, which immediately grew up again as often as they were cut off. The number generally ranged from seven to nine, though Simonides gives it fifty, and some historians a hundred, and even more. Its mouths, which were as numerous as its heads, discharged a subtle and deadly venom. The destruction of this reptile was one of the twelve labours of Hercules.

Hydra, a fresh-water polyp, the simplest and most familiar representative of the class Hydrozoa (q.v.), sub-kingdom Cœlenterata (q.v.). The animal consists of a tube, varying from $\frac{1}{4}$ to $\frac{1}{2}$ inch in length, closed at the proximal end by an adhesive plate (pedal disc), whereby it is commonly attached to some water weed; at the other (distal) extremity is the mouth, at the apex of a blunt cone (hypostome), round whose base arise from six to

Fig. 1.

Semi-diagrammatic longitudinal section of an adult specimen, with reproductive organs and a bud (*b*); magnified eight diameters. (After Marshall and Hurst.)

eight tentacles. These are slender tubes closed at the end, but continuous internally with the main cavity of the animal; they have a warty appearance and, according to their degree of contraction, may be either small rounded nodules or stretch out to several times the length of the body. The prey, which is lacerated by the thread-cells to be presently described, is drawn by the tentacles into the mouth. The body-wall consists of three distinct layers: 1. The Ectoderm, or outer covering, consists of the following kinds of cells: (1) covering cells in a single layer, subconical, with the broader ends outwards. (2) Muscle-cells, whose base forms a filament, disposed longitudinally. (3) Interstitial cells, small, rounded and placed in groups between the bases of the larger cells. (4) Endoblasts, so called because they contain the thread-cells (endocysts, nematocysts). These latter have rather a complicated structure; they consist of an ovoid sac, at the outer end of which the wall is invaginated or tucked in to form a long tube coiled up like a string; the commencement of the invaginated

portion contains some pointed barbs, the end is filiform and pointed. The young endoblasts, in which the development of the thread-cells is just beginning, are situated deeply among the interstitial cells; when mature they are placed on the surface, and form noticeable prominences between the covering-cells; the endoblast remains as a sharply-defined capsule round the thread-cell, and near the aperture of invagination it gives out a little process (endocil), which seems to serve the purpose of a trigger, for upon touching it the tube contained in the thread-cell is suddenly everted, and then presents the appearance of a long pointed filament, with barbs, disposed in circles of three each, at its base. It is, however, only certain forms of irritation which produce this effect; it seems to be under the control of the nervous system. (5) Nerve-cells,

with numerous processes, some of which are continuous with the endoblasts. (6) Glandular cells, which are restricted to the pedal disc. II. The Endoderm, or internal layer, consists of three kinds of ciliated cells: (1) a layer of large cells which often contain granules of greenish matter resembling that of leaves (chlorophyll). They have the power of throwing out processes (pseudopodia) during digestion, and almost always have empty spaces or vacuoles in them; they may furthermore give rise to muscular filaments, both circular and longitudinal. (2) Small glandular cells in the hypostome. (3) Glandular cells with vacuous spaces at the base of the body-cavity. III. The Mesoderm is a thin structureless lamella, separating the ectoderm and endoderm.

The hydra reproduces by two distinct modes: (1) asexually by gemmation. When the weather is warm and food abundant, a hollow outgrowth takes place from the side of the body of the parent; a mouth and tentacles are formed at its distal extremity, and eventually it separates by constriction of its base, and commences an independent existence. Several buds may form at once, and these may even produce secondary buds before their separation from the parent, but this formation of colonies is merely temporary. (2) Sexual reproduction takes place when the conditions of life become unfavourable—e.g. if a hydra which has just begun to bud be placed in a vessel in which food is scarce, sexual organs will be formed and the bud will not improbably be absorbed. The male organs (testes) are conical swellings, situated not far below the tentacles; generally they are more than one in number. They arise by the multiplication of the interstitial cells of the ectoderm, and when mature their contained spermatozoa are shed into the water. The ovum is as a rule single, and is due to the development of one of a mass of interstitial cells; the surrounding cells form a protective capsule which eventually retracts and leaves the most prominent part of the ovum bare to receive the spermatozoa. After this the ovum undergoes segmentation, a hard capsule is formed around it, and it falls to the bottom and there develops into a young hydra. Prior to sexual reproduction the hydra often retires into the shade

Fig. 2.

A, a thread-cell with the thread not everted; highly magnified. B, a thread-cell, after the evagination of its contents; highly magnified. The filament, if completed on the scale of the drawing, would have a length of 12 inches. (After Gibson.)

of moss or similar dark objects. As regards its reproductive organs it seems most probable that hydra has undergone great modifications as compared with other hydrozoa, and that its simplicity is not primitive but the result of degeneration. The food of hydra consists of organisms more minute than itself, which it is able to paralyse by its thread-cells; after the nutritive portion of these has been extracted the effete portions are ejected through the mouth. The animal can creep slowly upon its disc and swim by the same organ, hanging suspended below the surface of the water; it creeps by bending the body, attaching a tentacle to the surface upon which it rests, and then moving the foot up to the tentacle and refixing it.

Various species of the genus Hydra have been described, as *H. viridis*, *H. fusca*, and *H. vulgaris*. The first is distinguished by the presence of green chlorophyll granules in the cells of the endoderm. It has been maintained that these were algae living within the cells in a state of Symbiosis (q.v.), but the facts that the green hydra does not lose its colour in the dark, that the coloured bodies have neither nucleus nor cell-membrane, and that they are found in the ovum where they originate from colourless bodies, tend to prove that they are integral parts of the animal.

If a hydra be cut in two, it appears that within certain limits each portion will develop into a complete animal; but the statement so often repeated, as the result of Trembley's experiments, that when a hydra is turned inside out the endoderm and ectoderm will mutually take on each other's functions, and the animal continue to live, is erroneous; the animal will, on the contrary, rectify its position, or, if prevented, it will perish. When a hydra captures a fragment of food too large to be taken into the mouth, it everts the endoderm so as to bring the digestive cells in contact with the food, but it speedily regains its original state; this explains the power it has of rapidly recovering after artificial inversion. Two hydræ can be permanently fused with each other either by pinning them together with bristles or by inserting one inside the other.

List of more important references in addition to the ordinary text-books of zoology: Kleinberg, *Hydra* (Leip. 1872); Jékeli, *Morphologisches Jahrbuch*, viii. (1882-83); Parker, *Proc. Roy. Soc.*, xxx. (1880); Lankester, *Nature*, xxvii. (1882-83); Korotnev, *Ann. and Mag. Nat. Hist.* (5) xi. (1885); Ischikawa, *Zeitschr. f. wiss. Zool.* xlix. (1890).

Hydragogues. See APERIENTS.

Hydrangea, a genus of plants of the natural order Hydrangeaceæ, which many botanists make a sub order of Saxifragæ, distinguished by having four to six petals, eight to twelve or many stamens, a more or less inferior ovary, and two to five styles. In hydrangea the flowers are in cymes, the exterior flowers sterile and dilated. Few species are known, and they are chiefly natives of the southern parts of North America, and of China and Japan. The species popularly known as the Hydrangea (*H. hortensis*) is a native of China and Japan, and has long been in cultivation there as an ornamental plant. It was introduced into Britain by Sir Joseph Banks in 1788, and speedily became very popular, being readily propagated by layers and cuttings, so as to be not only a favourite greenhouse plant, but a frequent ornament of cottage windows. In the south of England, and south-west of Scotland, it endures the open air. It seems almost impossible to water it too freely; and in favourable circumstances it becomes a magnificent shrub. A plant in Devonshire has had 1000 large cymes of flowers expanded at once. The flowers, generally pink, are sometimes blue; the blue colour is owing to peculiarities of soil.

Peat and iron ore are said to be productive of blue flowers in the hydrangea. *H. Japonica*, introduced into Europe from Japan by Siebold, is remarkable

Hydrangea (*Hydrangea hortensis*).

for its very large cymes of flowers.—*H. nirea* and *H. quercifolia*, American species, are not unfrequently to be seen in flower-gardens in North America.

Hydrates are compounds of water with elements or with other compounds. The term *hydroxide* is one which is sometimes used as a synonym of *hydrate*, and indeed it may be said that we have no certain means of distinguishing the one from the other. The distinction between the two is that in the hydrate the water is supposed to be present as water, and without any rearrangement of the molecules, while in the hydroxide the water is considered to have lost its identity, its constituent atoms having entered into new combinations. As a typical example of a hydrate we may instance crystallised sulphate of copper, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, which contains the water so loosely combined that it is driven off by prolonged heating, and the white anhydrous sulphate, CuSO_4 , is produced. Here the water is apparently present as water, and necessary to the crystalline form, and is therefore called water of crystallisation. When nitric anhydride, N_2O_5 , unites with water it forms nitric acid, $\text{N}_2\text{O}_5 \cdot \text{H}_2\text{O}$ or HNO_3 , but this is not regarded as a hydrate, because the nitric acid cannot lose the water without also losing its characteristic properties. The whole question is full of difficulties, and is at present quite theoretical; different chemists using the terms above mentioned in different senses.

Hydraulic Cranes. See CRANES.

Hydraulic Engines or Motors are often conveniently used when water under a high pressure is obtainable, and where work is intermittently required, as in capstans, winches, &c.; they do not differ essentially from steam engines. The water acts by difference of pressure, i.e. it is admitted at a high pressure at the beginning of the stroke, and exhausted at a low pressure at the end of the stroke, thus giving a reciprocating motion to the plunger. The velocity of the piston has to be kept low to avoid injurious shocks in suddenly bringing the column of water to rest; since they work under very much greater pressures than steam engines (usual pressure 700 lb. per sq. in.), they can be much smaller. A common form is the three-cylinder single-acting engine; in each cylinder works a plunger; water is admitted by valves behind the plungers and forces them out; at the conclusion of the out-stroke the pressure water-supply is cut off, and the

exhaust valve opened, allowing the plunger to push the water out of the cylinder on the return stroke, and so on. There are two chambers in the framing, and one passage or port into the bottom of the cylinder; during the working of the engine the cylinder oscillates, and at the right time puts one or other of the two chambers in communication with the interior of the cylinder by means of this port; one chamber is open to exhaust-pipe, the other to supply-pipe. The plungers are connected to a three-throw crank. The great advantage of the single action is that shocks are avoided at the dead centres; the three cranks ensure a very uniform turning force on the crank shaft, and also enable the engine to start in any position.

Hydraulic Main. See GAS.

Hydraulic Mortar. See CEMENTS.

Hydraulic Press, often called Bramah's press, from the inventor, Joseph Bramah (q.v.), depends for its action on the principle that a pressure exerted on any part of the surface of liquid is transmitted undiminished and equally

Hydraulic Press.

in all directions through the mass (see HYDROSTATICS). The annexed figure represents the essential parts of the machine, minor details of construction being omitted. F is a strong cast iron or cast-steel cylinder, open at the top; B is a plunger or ram which fits watertight into the cylinder; to prevent leakage a leather ring U-shaped in section is placed in the cavity *c*; any water trying to leak out forces the two sides of this ring hard against the piston and the side of the cavity, and the greater the pressure the tighter it keeps. This form of packing is now often replaced by an ordinary stuffing-box filled with hemp packing. A pipe, G, leads from the cylinder to a force-pump, H. By means of this pump water can be forced from the tank, T, through the pipe G into the cylinder, thus pushing the plunger or ram, B, upwards. The ram carries on its top a platten or table, on which the bales, &c., to be pressed are placed; the rising of the platten presses them against the entablature or upper plate, A, which is held in position by the columns C. The bale can thus be squeezed to any extent desired.

The power of the press is readily calculated; let the diameters of the pump plunger, K, and ram, B, be *d* and *D* inches respectively, then any downward pressure on K becomes an upward pressure on B magnified $\frac{D^2}{d^2}$ times. Suppose, for instance, that the pressure on K was 500 pounds, and that the diameters are 1 and 10 inches respectively, then the upward thrust would be $500 \cdot \frac{10^2}{1^2} = 50,000$ pounds; very enormous pressures are therefore readily

obtained, and in consequence of the slow motion there is extremely little waste of power in friction. It is thus a very efficient mechanism. The pump can either be a hand-pump worked by a lever, L, as in sketch, or it may be worked by a steam engine, as is the case in the modern powerful presses. The enormous multiplying power of this contrivance has led to its most extensive use; for example, compressing cotton and wool bales, &c., expressing oils, bending iron plates and bars, lifting heavy weights (lifts and hoists), raising into position bridge-girders (hydraulic jacks), &c. Presses of enormous power are now superseding the huge steam-hammers in large steelworks, obviating the unpleasant vibrations and ensuring sounder metal.

Hydraulic Ram, a simple and conveniently applied mechanism, by which the energy of water falling from a height, *h*, can be made available to force a portion of itself to a greater height, *H*. There is a supply-reservoir, fed, say by a spring, from which a strong pipe, R, conducts the water to the ram at a lower level. The ram has two valves, one, A, opening downwards and inwards, the other, B, opening upwards and outwards; the weight of these valves is such that when the water is at rest its normal pressure is unable to keep them from falling, so that in this condition A would be open and B shut. A cottar on the rod of A keeps it from opening more than a certain amount, and this can be adjusted; the valve B opens into an air-vessel, C, from the bottom of which the delivery pipe, D, leads away. The action is as follows: the water flows from the reservoir through the pipe R, and rushes out through the now open valve A away to the waste-pipe; in doing so it acquires considerable velocity, and its pressure therefore on the under side of the valve A increases, and finally becomes great enough to close it. The flow of the water being thus suddenly checked, produces a great reaction, and by its momentum opens the valve B, and forces a portion of the water into the air-vessel C; the energy being expended, the pressure falls again, B closes, and A opens once more, enabling the water to rush out to the waste-pipe, and so the whole operation is repeated. The two valves thus alternately open and close, and water is delivered each time into the air-chamber, C, the air in which being compressed acts as an air-cushion, keeping up a constant delivery through the pipe D.

Section of Hydraulic Ram.

The small air vessel, E, is for diminishing the shocks, and has a small relief valve in it to admit air when necessary; it is self-acting. The hydraulic ram was an invention of Montgolfier (1797), but has been greatly improved; its mechanical efficiency is good, and for raising small quantities of water, such as are necessary for the supply of single houses, farm-

yards, &c.—where water at the lower level is plentiful and cheap, it is a most useful piece of mechanism. It can even be made to work a pump, and so to deliver a supply of pure water when the motive water is muddy or impure.

Hydraulics. See HYDROMECHANICS.

Hydrides. This term is applied both to combinations of hydrogen with metals, and to similar combinations with organic or compound radicals. Hydrogen forms hydrides with a number of the metals, as, for instance, arsenic, antimony, copper, and potassium. The first two of these are the well-known gases, arseniuretted hydrogen, AsH_3 , and antimonuretted hydrogen, SbH_3 . In the case of organic radicals, the hydride of ethyl, C_2H_5H , for instance, was at one time supposed to be a different substance from dimethyl, CH_3CH_3 , but these were eventually proved to be identical, so that the term hydride, in this sense, is now obsolete.

Hydrobromic Acid. (1) *gas*, HBr , invisible, pungent, acid reaction, fumes in moist air, liquid at $-69^\circ C.$, solid at $-100^\circ C.$; prepared from a bromide plus phosphoric acid, or phosphorus tribromide plus water. (2) *Aqueous solution*, analogous to commercial hydrochloric acid, is weakened by boiling until HBr sinks to 47 per cent., then distils unchanged. See BROMINE.

Hydrocarbons belong to the department of organic chemistry, and may be shortly defined as compounds of carbon and hydrogen, and nothing else. Despite their apparently simple nature, they are frequently very complex, and exist in such numbers as to bewilder the beginner in chemical study. Fortunately, they can be gathered into groups, each having distinctive characters, and the members of which are closely related to each other. The chief of these are the Paraffins, the Olefines, the Acetylenes, the Benzene (q.v.) series, and the Anthracene (q.v.) group.

The *Paraffins* are found in natural petroleum as well as in the products of the destructive distillation of coal, and are known as *saturated hydrocarbons*. By this is meant that the carbon present is already saturated (so to speak) with hydrogen, and has no tendency to unite with other elements or molecules. Graphically, carbon may be represented as C —i.e. with four arms, each one of which is capable of being united to one atom of hydrogen; and when all four arms are so united, a *paraffin* is

produced; thus, $H-C-H$. But, instead of the

single atom of hydrogen, one arm (or all the arms) may be engaged by such a group as CH_3 , so that we get another paraffin, CH_4 , CH_5 . Thus we go on forming a series, each member of which differs from the preceding one in having an extra CH_2 . Thus:

and so on indefinitely. It will, however, be noticed that when we pass to a higher member than propane, by replacing an atom of hydrogen by CH_3 , we may do so in two ways, according as the atom replaced is in the CH_3 group at either end, or the CH_2 group in the centre. The result is that two hydrocarbons are possible—viz. $CH_3-CH_2-CH_2-CH_3$, and also $\begin{array}{l} CH_3 \\ | \\ CH_2 \end{array} > CH-CH_2$. In like manner,

as we proceed further, wider scope is given to us, the result being that when Tridecane, $C_{13}H_{28}$, is reached, it is theoretically possible to recognise 802 such bodies, all having the same percentage composition, but differing more or less in characters. Many of these isomers are already known.

The paraffins are characterised by their indifference to chemical action, being unacted on by caustic potash, sulphuric or nitric acid. The general formula of the paraffins is C_nH_{2n+2} , where n represents the number of atoms in the formula.

The *Olefines*, C_nH_{2n} .—The chief of these are Ethylene, C_2H_4 , Propylene, C_3H_6 , Butylene, C_4H_8 , Amylene, C_5H_{10} , &c.; and it will be observed that in all of them the percentage composition is identical, and that each member differs from the lower one by the addition of CH_2 . When acted on by chlorine, bromine, or iodine they readily form oily liquids, such as Dutch liquid, and, generally speaking, they markedly differ from the paraffins in the readiness with which they unite with other bodies.

Hydrocele (Gr. *hydro*, 'water,' and *kèle*, 'a swelling') is a dropsy of the tunica vaginalis, the serous membrane investing the testis. It occurs as a smooth, pear-shaped swelling, painless, but sometimes causing a slight uneasiness from its weight. The quantity of fluid in the sac may amount to 40 ounces. Hydrocele may occur as a result of acute inflammation, but it most commonly comes on without any apparent local cause. It is most frequently met with about or beyond the middle period of life, and generally in persons of feeble power, or with a tendency to gout; sometimes, however, it occurs in young children, either in the same form as in adults, or as what is termed *congenital hydrocele*. The treatment may be *palliative* or *curative*. The palliative treatment consists in the use of suspensory bandages, and tapping from time to time. Tapping seldom gives more than temporary relief, the swelling usually regaining its former bulk in three or four months. The curative treatment consists in setting up inflammation in the tunica vaginalis, by the injection of tincture of iodine, so as to obliterate the cavity, or by excision of the whole or part of the sac.

Hydrocephalus. Under this term, which literally means 'water in the head,' are included three distinct diseases—viz. acute hydrocephalus, chronic hydrocephalus, and spurious hydrocephalus, or, as Dr Marshall Hall termed it, hydrocephaloid disease.

Acute Hydrocephalus, or, as it is now generally and more satisfactorily termed, *tubercular meningitis*, is essentially an inflammation of the membranes of the brain due to the presence of Tubercles (q.v.). The occurrence of fluid within the skull or the brain, though frequent, is merely a secondary and subordinate phenomenon. It is an extremely fatal form of disease, common in childhood, much less so during adult life. The symptoms are very variable and perplexing, so that only the barest outline of the most frequent and important can be attempted here. There is usually a premonitory period of some days or weeks, during which the appetite and digestion are disturbed, the disposition is altered either in the direction of listlessness or irritability, the strength impaired, and the body becomes slightly thinner. The first distinct symptom of the disease is usually severe headache, with sickness and feverishness; the pulse is rapid and the temperature raised, but variable. Vomiting very often occurs at this stage, and sometimes a peculiar cry at intervals, which if present is very characteristic.

In this first stage of hydrocephalus, which most commonly lasts two or three days, the symptoms generally are those of excitement. In the second stage the pulse becomes irregular, variable, and often slow. General heaviness and stupor come on. The light, which annoyed the child in the first stage, is no longer a source of annoyance; the pupils become dilated, the power of sight is imperfect or lost, and squinting is almost always

to be observed. The little patient now lies on his back in a drowsy condition; and at this period spasmodic twitchings, convulsions, or paralysis may appear. The exertions are passed unconsciously. The second stage may last a week or two, and is often attended by deceptive appearances of amendment, the child not infrequently regaining the use of its senses for a day or two, but then relapsing into a deeper stupor than before. The symptoms in the third or last stage, which may last only a few hours or may extend to a fortnight, are very similar to those in the second, except that the pulse again becomes very rapid, beating sometimes so quickly that it can scarcely be counted, and gradually gets more and more weak till the patient expires. The characteristic appearances after death are the presence of tubercles in the membranes of the brain, usually near the base, and generally more or less softening of the central part of the brain, with the effusion of serous fluid into the ventricles.

It must not be supposed that the stages described above can be observed in every case. There is, in fact, hardly any disease whose course is so variable and so apt to mislead those observing it. In its earlier stages its recognition is sometimes almost impossible; yet it is only then that any treatment can be expected to be successful. Cold applied to the head, leeching, and purgation sometimes appear to do good; but in the vast majority of cases the disease proves rapidly fatal. Recovery has been proved to take place only in some few exceptional instances.

Chronic Hydrocephalus is a perfectly distinct disease from that just described; while the latter is an inflammation, the former is a dropsy. In chronic hydrocephalus a watery fluid collects within the skull, before the bones have united to form the solid brain-case, and by pressure outwards causes them to separate, and increases the size of the head sometimes to an enormous extent. Thus Dr David Monro relates the case of a girl six years old whose head measured 2 feet 4 inches in circumference. While the skull is rapidly enlarging, the bones of the face grow no faster than usual, and the great disproportion of size between the head and the face is at once diagnostic of the disease. This disorder sometimes commences before birth, and almost always in early childhood, before the fontanelles and sutures of the skull have closed. In some rare cases it has occurred later, as, for example, at seven or nine years old, and the closed sutures have opened under the augmenting pressure. When the sutures will not yield, death from pressure on the brain speedily ensues. Most children with chronic hydrocephalus either recover or die in infancy; but a few survive, bearing their complaint to adult life, or even to old age. Blindness, deafness, palsy, and idiocy—one or more—are commonly associated with this disease, but occasionally the intellect and senses are sufficiently perfect for the ordinary requirements of social life.

The results of treatment are generally not encouraging, though sometimes benefit appears to result. It may be attempted by internal remedies or by surgical appliances. The medical treatment must in favour consist in the administration of diuretics, purgatives, and especially mercury, which may be given in the form of calomel in minute doses, and applied as ointment externally. The surgical expedients are bandaging and puncturing the head. The latter has in many cases certainly prolonged life, although the disease has finally conquered. Neither of these means is applicable after the bones of the skull have united.

This disease occasionally occurs in adult or

in advanced life, after enlargement of the head has become impossible. Stupor, paralysis, and an inability or unwillingness to speak are in these cases the most prominent symptoms. Dean Swift's death was due to this disease, and it is recorded that during the last three years of his life he remained in a state of silence, with few and slight exceptions.

Spurious Hydrocephalus resembles acute hydrocephalus in many of its symptoms, and has often been mistaken for it. Instead, however, of being an inflammatory disease it is a disease of debility, and is due to a deficient supply of blood to the brain. The following are, according to Watson, the distinctive characters of this spurious hydrocephalus: the pale, cool cheek; the half-shut, regardless eye; the insensible pupil; the interrupted, sighing respiration; and the state of the unclosed fontanelle. If the symptoms are those of acute hydrocephalus the surface of the fontanelle will be convex and prominent; while if they are due to spurious hydrocephalus, and originate in emptiness and want of support, the fontanelle will be concave and depressed. The remedies in this disease, which readily yields to treatment, are nourishing diet, small doses of wine or even of brandy in arrowroot, decoction of bark, ammonia, &c.

Hydrocharidea. See ANACHARIS, VALLISNERIA, WATER-SOLDIER.

Hydrochloric Acid (sym. HCl; equiv. 36.5) is one of the most important compounds in inorganic chemistry. If the two gases which enter into its composition (hydrogen and chlorine) be mixed in equal volumes they will remain without action upon each other if kept in the dark; but as soon as they are brought into direct sunlight they unite with a loud explosion, and hydrochloric acid gas is the result. The principal characters of this gas are that it is colourless, intensely acid, irrespirable, and even when largely diluted is very irritating to the lungs and eyes, and very injurious to vegetation; that it is heavier than air (its specific gravity being 1.2474, air being taken at 1.000); that it can be condensed into a colourless liquid; that it is very soluble in water, and that it is neither combustible nor a supporter of combustion. When allowed to escape into the air it produces white fumes by condensing the atmospheric moisture. If the air be previously dried no such fumes are apparent.

The solutions of this gas in water form the acid which was first known as *Spirit of Salt*, then as *Muriatic Acid*, and which is now termed *Hydrochloric* or *Chlorohydric Acid*. A saturated watery solution of this gas at 40° (4.4° C.) has a specific gravity of 1.21, and consists of 1 equivalent of the gas dissolved in 3 equivalents of water. It forms a colourless, fuming liquid, which acts as a caustic. On heating it the gas is evolved abundantly until the temperature reaches 230° (110° C.), when there distils over a diluted solution, having a specific gravity of 1.1, and consisting of 1 equivalent of the gas and 8 equivalents of water. It is to these solutions of hydrochloric acid that the term *hydrochloric acid* is far more commonly applied than to the gas itself. They possess the ordinary characters of an energetic acid, and neutralise the strongest bases. The neutralisation is, however, not in consequence of the acid combining with the oxide, but is due to the simultaneous decomposition of the acid and of the oxide, water and a metallic chloride being formed. If M represents the metal the reaction is expressed by the equation $M\text{O} + \text{HCl} = \text{MCl} + \text{H}_2\text{O}$. All metals which at a red heat decompose water also decompose this acid, and cause an evolution of hydrogen, the

reaction being expressed as follows: $M + HCl = MCl + H$. Hydrochloric acid gas is a common gaseous volcanic product. Free hydrochloric acid in a very dilute form is also a constituent of the gastric juice of man and animals, and plays an essential part in the digestive process.

Commercial *muricatic acid*—to use the name employed by manufacturing chemists—is made by heating in iron cylinders common salt (chloride of sodium) and oil of vitriol (hydrated sulphuric acid), and condensing the evolved gas in water contained in a series of stoneware Wolffian Bottles (q.v.), the reaction being explained by the equation:

This commercial acid may contain various impurities—as, for example, iron (which gives it a bright deep yellow colour), the chlorides of sodium and arsenic—the latter being derived from the oil of vitriol—sulphuric and sulphurous acids, chlorine, &c., from which it can be purified to a great extent by dilution and redistillation. 'If pure,' says Miller, 'the acid should leave no residue when evaporated; on saturating it with ammonia it should give no precipitate of oxide of iron; sulphuretted hydrogen should produce no turbidity in it, which would be the case if arsenic, free chlorine, or sulphurous acid were present; and on dilution with three or four times its bulk of water no white cloud of sulphate of baryta should be produced by the addition of chloride of barium.' The presence of hydrochloric acid, or of the soluble chlorides in solution, may be detected by the addition of a few drops of a solution of nitrate of silver, which occasions the formation of a white curdy precipitate of chloride of silver, which is insoluble in nitric acid, but dissolves in a solution of ammonia.

Liquid hydrochloric acid (under the name of spirit of salt) was known to the alchemists. Hydrochloric acid gas was discovered by Priestley in 1772; and Davy in 1810 ascertained that it was composed of chlorine and hydrogen. In many respects hydrobromic, hydrofluoric, and hydriodic acids resemble hydrochloric acid.

Hydrocele, a Tumour (q.v.) with watery contents in the tunica vaginalis of the testes.

Hydrocyanic Acid, HCN or HCy , known also as Prussic Acid, from its having been first obtained by Scheele in 1782 from the substance known as Prussian or Berlin Blue, is of almost equal interest to the chemist, the physician, and the toxicologist.

(1) *Chemistry*.—Pure anhydrous hydrocyanic acid is a colourless, highly volatile liquid, with a specific gravity of 0.697 at 64° F. It boils at 80°, and solidifies into a crystalline mass at 5° F. It possesses a very penetrating odour, resembling that of peach-blossoms or oil of bitter almonds. It burns with a whitish flame, reddens litmus paper slightly (its acid properties being feeble), and is very soluble in water and alcohol. Pure hydrocyanic acid may be kept unchanged if excluded from light, which occasions its decomposition, and the formation of a brown substance known as paracyanogen. Hydrocyanic acid is readily obtained by distillation from the kernels of bitter almonds and many kinds of stone fruit, from the leaves and flowers of various plants, and from the juice of the tapioca plant (*Jatropha manihot*). Anhydrous hydrocyanic acid may be obtained by the action of concentrated hydrochloric acid on cyanide of mercury. The diluted hydrocyanic acid of the British and other pharmacopœias is, however, of more practical importance. It is made (*British Phar-*

mucop.) by distilling ferrocyanide of potassium with dilute sulphuric acid, and is standardised to a strength of 2 per cent. When kept for any length of time it is extremely apt to decompose.

The ordinary tests for hydrocyanic acid are (1) the peculiar odour; (2) the nitrate of silver test—there being formed a white precipitate of cyanide of silver, which is soluble in boiling nitric acid; (3) the formation of Prussian blue, by adding to the fluid under examination a solution of some proto- and per-salt of iron, by then saturating with caustic potash, and finally adding an excess of hydrochloric acid, when, if hydrocyanic acid is present, we have a characteristic blue precipitate; (4) the sulphur test, which is the best and most accurate that has yet been discovered. To the suspected liquid add ammonia and yellow sulphhydrate of ammonium; evaporate the liquid in a watch-glass to dryness, occasionally adding ammonia till the excess of sulphhydrate of ammonium is decomposed. Add water, and acidify with hydrochloric acid. If hydrocyanic acid be present the sulphocyanate of ammonium which has been formed gives a blood-red solution on the addition of a ferric salt.

(2) *Medicinal Uses*.—Diluted hydrocyanic acid is used externally as an ingredient of lotions to diminish itching in skin diseases. In 2 to 8 minim doses it is given internally to diminish irritability of the stomach, to relieve gastro-intestinal pain, vomiting, and functional palpitation of the heart. Given by the mouth or by inhalation it is also useful in allaying cough in phthisis, hooping-cough, bronchitis, &c. All these applications depend upon its action in deadening sensory nerves.

(3) *As a Poison*.—Hydrocyanic acid is one of our most energetic poisons, and is frequently employed both for murder and suicide. When a *small* poisonous dose (about half a drachm of the 2 per cent. acid) has been taken the first symptoms are weight and pain in the head, with confusion of thought, giddiness, nausea (and sometimes vomiting), a quick pulse, and loss of muscular power. If death result this is preceded by convulsions and involuntary evacuations. When a *large* dose has been taken (as from half an ounce to an ounce of the 2 per cent. acid) the symptoms may commence in a few seconds, and it is seldom that their appearance is delayed beyond one or two minutes. 'When,' says Dr A. S. Taylor, 'the patient has been seen at this period he has been perfectly insensible, the eyes fixed and glistening, the pupils dilated and unaffected by light, the limbs flaccid, the skin cold and covered with a clammy perspiration; there is convulsive respiration at long intervals, and the patient appears dead in the intermediate time; the pulse is imperceptible, and the respiration is slow, deep, gasping, and sometimes heaving or sobbing.' The patient survives for a longer or shorter period, according to the dose. According to Dr Lonsdale, death has occurred as early as the *second* and as late as the *forty-fifth* minute; the poison acts as a paralytant to the whole nervous system. Death is due to paralysis of the heart in the more rapid cases, and to paralysis of the respiration in those which occur more slowly.

Where the fatal action is so rapid antidotes are of comparatively little value. Chlorine, ammonia, cold affusion, and artificial respiration are the most important agents in the treatment. The first two should be used with great caution, and only by the medical practitioner. Cold affusion on the head, neck, and down the spine is a valuable remedy. Artificial respiration (see RESPIRATION, ARTIFICIAL) should never be omitted.

Hydrodynamics, in its complete generality, is the science which treats of the motions and equilibrium of a material system, part or all of

which is fluid. In accordance with modern dynamic nomenclature (see DYNAMICS) we should discuss it under the two headings Hydrokinetics and Hydrostatics. The historic usage of the term has, however, so fixed itself that we generally regard hydrodynamics as excluding hydrostatics and as dealing only with kinetic problems. Originally, as the derivation of the words at once show, hydrodynamics and hydrostatics referred only to the motion and equilibrium of liquids; but as our knowledge of the physical properties of all kinds of fluid, liquid and gaseous, increased, it was recognised that they had much in common from a dynamic point of view, and the terms became extended in their application as defined above. Thus the floating of a balloon in air depends on the same hydrostatic principle as the floating of a ship on water. The simpler and some of the more practical problems of hydrostatics will be found treated under that heading. In its practical engineering aspects hydrodynamics is known as hydraulics, including such important subjects as the construction of canals, breakwaters, docks, pumps, water-pipes, water-wheels, and so on, most of which have separate articles to themselves. Here we shall confine ourselves to the scientific principles of the subject, using familiar cases as illustrations.

The study of hydrodynamics has led to the conception of what is called the *perfect fluid*. It may be defined as a substance incapable of resisting the smallest deforming stress. For instance, no portion of such a fluid can resist, even for a moment, a longitudinal pressure if unsupported by a lateral pressure. The logical consequence of this definition is that, if the fluid is at rest, the pressure at a point is the same in all directions; for if it were not so there would be a deforming stress, and therefore a yielding of the fluid, and equilibrium could not exist. By similar reasoning we may show that, if the pressure varies from point to point in a fluid at rest, there must be an external force acting on the fluid in the direction in which the pressure is increasing. Thus, in virtue of gravity, atmospheric pressure decreases as we ascend, and the pressure in the ocean or any other body of water increases as we descend. So long as we are dealing with equilibrium of fluids we meet with nothing inconsistent with the definition of the ideal perfect fluid. Across every interface separating two contiguous portions of the fluid the mutual stress is of the nature of a pressure wholly normal to the interface.

When, however, we pass to cases of fluid motion we find that the properties of the perfect fluid are very far from being realised in nature. The smallest relative motion amongst the different parts of a fluid brings into play mutual stresses which are not normal to the interface between two contiguous portions. These tangential stresses tend to destroy the relative motion, existing only so long as the relative motion exists. They are thus partly analogous to resistances due to friction in the dynamics of solid bodies—hence the term fluid friction (see VISCOSITY) frequently employed to denote the property that discriminates actual fluids from the ideal perfect fluid. Fluid friction, however, differs from friction in one marked particular; it has no significance in static problems. It is wholly kinetic. The gradual stilling of troubled waters, the calming of the wind, the slackening in speed of the water in a stream as we pass from the centre and surface portions towards the banks or bottom are familiar examples of the effects of fluid friction.

Under certain circumstances the tangential stresses thus brought into play not only retard the motion of the more swiftly moving parts of the fluid, but even accelerate the motion of the more

slowly-moving parts. Thus a rapidly-flowing river entering the sea draws along with it a considerable quantity of the original ocean water. The effects of a draught of air are felt far beyond the direct course of the main current. It is impossible, in fact, to mark off clearly the boundaries of a current flowing in fluid of the same kind. In like manner, the eddies formed in the wake of a solid body moving through either air, water, or other fluid could not be produced if it were not for the existence of these tangential stresses. In every case the final result is a dissipation of energy (see ENERGY); but in the majority of cases of practical importance the rate of dissipation is so slow—in other words, the tangential stresses are so small in comparison with the other effective forces acting—that the properties of the perfect fluid go far to explain many hydrokinetic phenomena. Some of these we shall now consider.

It has been already pointed out that the equilibrium of a fluid under the action of gravity or other force depends upon the manner in which the pressure varies in the direction of the force. Now a force has always a definite direction; and consequently in all directions perpendicular to the direction of the resultant force acting at a point in the fluid there can be no variation of pressure. Thus, from any one point we can pass to an infinity of neighbouring points at which the pressure is the same; from each of these again to an infinity of others; and so on indefinitely. We thus arrive at the conception of a surface in the fluid, at every point of which the pressure is the same. Such a surface is called a surface of equal pressure, and one of its essential properties is that it is perpendicular at every point of it to the resultant force there. In the case of fluids at rest under the action of gravity these surfaces are also called level surfaces, and are for all practical purposes essentially horizontal planes. A consideration of these principles leads easily to the conclusion that equilibrium in a fluid mass cannot exist if the pressures at two points at the same level differ, or if the pressures are the same at two points at different levels. These two conditions are essentially one and the same; and when they are fulfilled, fluid motion must take place (see such articles as ATMOSPHERE, WIND, WAVE, SIPHON, and ARTESIAN WELLS for familiar illustrations of these principles).

The discharge of fluids through orifices includes a number of very important phenomena, some of which we shall discuss in detail. The vessel MAB (fig. 1) is provided at D, C, E, *a* with apertures

Fig. 1.

which may be closed when desired. Let the vessel be filled with water up to the level MA; then, if the orifice *a*, which looks vertically upwards, is opened, a jet of water will be projected up, and will reach very nearly to the height MA. If it were not for fluid friction and the consequent dissipation of energy the jet would reach the height MA. As soon as the orifice *a* is opened, the water

surface there being exposed simply to the pressure of the atmosphere is under the same pressure as the much higher surface MA. Hence a flow takes place and will continue to take place until the surface of the water MA has sunk to the level of the water at a . The experiment shows that the jet is projected with a velocity very nearly equal to that which would be acquired by a body falling under gravity from the level AM to the level a . This velocity is given by the relation $v^2 = 2gh$, where g is the acceleration due to gravity and h the difference of level mentioned. Similarly, if the orifices at D, C, E are opened, the issuing jets will be projected with speeds whose squares will be found to be very approximately proportional to the differences of level between the upper surface MA and the respective orifices. This may be proved experimentally by constructing the orifices so that the discharge is initially horizontal, and then measuring the range, BK or BL, reached by the several jets. Thus, assuming the law just given, commonly called the theorem of Torricelli, we may show that the square of the range BK is equal to four times the product of the differences in level of the orifice D below A and above B, that is, $4AD \cdot DB$. Hence if we describe a semicircle AGB on AB as a diameter, the horizontal lines DF, CG, EH meeting this semicircle will be half the horizontal ranges corresponding to the respective orifices.

The height of the free water surface above the orifice from which the water is issuing is technically called the *head*. The greater the head the greater is the pressure at the level of the orifice, and the more available the water for practical purposes. Part of the head is consumed in overcoming frictional resistances; for well-formed simple orifices about 6½ per cent. of the whole head is so expended. The discharge from any orifice in a given time will depend obviously on the size of the orifice and on the available head. Experiment shows, however, that for sharp edged orifices in a wall the discharge is distinctly less than the simple theory would indicate. In such cases the section of the jet is smaller than the section of the orifices in the ratio of about 5 to 8. This is sufficiently explained by the convergence of the streamlets in the fluid which ultimately form the jet; and this convergence continues for a little distance beyond the orifice, producing the phenomenon of the *vena contracta* or contracted vein. We have seen how the speed of efflux is measured by means of the parabolic path of the jet; this speed multiplied by the number of seconds in a chosen interval of time, and by the *effective* (unknown) area of the orifice gives the whole discharge in that interval. This discharge can be easily measured; and thus the data are complete for finding the effective area of the orifice and comparing it with the real area. By furnishing an orifice with a short mouthpiece of the form of the contracted vein, we may regard the smallest cross section of the mouthpiece as the true orifice. In this case the effective area and the real area are the same.

In these simple cases of efflux the energy of efflux is wholly explained as being derived from the hydrostatic head of water. The pressure due to this head is the weight of a column of water of unit cross-section and of a height equal to the head. Thus, if ρ is the density of the water, so that ρg is the weight of unit volume, the pressure p due to a head h is

ρgh . Thus, by Torricelli's theorem, $\frac{p}{\rho}$ is half the

square of the velocity with which a jet would be projected through an orifice made at a place where the pressure is p . Hence we may regard this ratio

$\frac{p}{\rho}$ as the energy per unit mass of water due to the

pressure p . But if the water is in motion with a speed v , its energy per unit-mass is on this account $\frac{1}{2}v^2$. If, further, the particular portion of the fluid considered is at a height x above a certain arbitrarily chosen level, defined as the level of zero potential energy, then its potential energy is gx . The whole energy possessed by the moving fluid is built up of these three parts due respectively to pressure, speed, and gravitation, and is given therefore by the expression $\frac{p}{\rho} + \frac{1}{2}v^2 + gx$. Now, in the case of a

steady frictionless flow along a determinate channel, the whole energy possessed by any unit-mass of the fluid must be the same; for at some time or other every element passes through the positions occupied at other times by other elements in the same streamline, and passes through them under the same dynamic conditions. Hence, neglecting the effects of friction, we arrive at the conclusion that the expression for energy just given is constant along any given stream-line. Take, for example, a pipe of uniform bore. If the flow is steady the invariableness of the cross-section requires the speed at every point to be the same. Hence as x diminishes

p must increase, so that $\left(\frac{p}{\rho} + gx\right)$ may remain constant. For a horizontal pipe x must be constant, and so of necessity is p . Now suppose the tube to be horizontal but of variable section; then, since x is constant, the expression $\left(\frac{p}{\rho} + \frac{1}{2}v^2\right)$ must also be

constant. But the speed v varies inversely as the section; hence p must be greatest where the bore is widest and least where the bore is narrowest. In other words, the cross-section and pressure increase together and diminish together. A familiar illustration of this is shown in fig. 2, in which water is escaping from a short cylindrical nozzle A. The

Fig. 2.

contracted vein occurs at c , so that, the velocity being greater there than at the open end of the tube, the pressure is less. But the pressure at A is the atmospheric pressure; and, consequently, if a tube be led from c to the vessel of water V, the water will be pushed up to some point b by the excess of the atmospheric pressure over the pressure at c .

When the effects due to friction are taken into account we see in a general way that the energy, instead of remaining constant as we pass along a stream-line, will steadily fall off. In the case of a uniform pipe this loss of energy will show itself in a more rapid falling away in the pressure. For instance, in a horizontal pipe of uniform bore the pressure will steadily diminish as we pass along in the direction of the flow. At the open end of the pipe (c , fig. 2) the pressure is that of the atmosphere; and this will gradually increase as we pass along the pipe against the flow until we come to d , where the pressure falls a little short of that due to the head of water in the vessel. This may be shown experimentally as indicated in the figure, in which the small upright tubes inserted in the horizontal pipe become filled with water to a certain height. In the construction of water works these and many

other problems in hydrokinetics receive their practical solution. In the motion and flow of highly compressible fluids, such as gases, we meet with theorems similar to those just discussed for liquids. The treatment, however, is necessarily more abstruse, and is far from complete if thermodynamic considerations are left out of account. See GASES, SOUND, THERMODYNAMICS.

The hydrokinetic problems connected with the motion of solids through fluids have their most important applications in questions which concern the artilleryman and the shipbuilder. In the practice of gunnery the law of the resistance to projectiles in air has been very fully worked out. At very high speeds the resistance is very great indeed; and it may be shown that an ordinary-sized projectile if dropped from an immense height (say 40 miles) could never, under the action of gravity alone, attain a speed of 800 feet per second. One great source of loss of energy of a body moving through a liquid is the formation of eddies and vortices in its wake. These are the direct result of tangential stresses acting between contiguous portions of the fluid moving with different speeds. In virtue of the same tangential stresses the eddying motions quickly die away, and the energy, as in all such transformations, takes the form of heat.

The best English treatises on hydrodynamics are Lamb's *Hydrodynamics* (1895) and Basset's *Hydrodynamics* (2 vols. 1888-89); see also Unwin's 'Hydraulics' in *Encyclopædia Britannica* (9th ed.).

Hydro-extractors. See DRYING-MACHINES.

Hydrofluoric Acid. See FLUORINE.

Hydrogen (sym. H; atom. wt. 1; Gr. *hydro*, 'water,' and *gennao*, 'to produce') is an elementary gas and the lightest substance known. It is colourless, odourless, and non-poisonous, although as ordinarily prepared it frequently contains traces of disagreeably smelling or of poisonous impurities. The gas when subjected to enormous pressure at an extremely low temperature can be reduced to the liquid state. In combination with oxygen it forms one-ninth part by weight of water, and it is a most important constituent of the tissues of animals and plants. It enters into the composition of a large number of manufactured substances and products used in the arts, medicine, &c., as, for instance, starch, sugar, vinegar, gutta-percha, alcohol, ether, benzene, aniline, indigo, morphia, &c. It is not found largely in nature in the free or uncombined state, but it does occur in some gaseous emanations from the earth, as in the solfataras of Iceland and in the petroleum regions of Pennsylvania. Being the lightest gas known, its density is often adopted as the standard of comparison for the densities of other gases. The density of atmospheric air compared with that of hydrogen as unity is nearly 14.5. As hydrogen possesses the lowest atomic weight of all the elements, the atomic weight of hydrogen is almost universally adopted by chemists as unity, and those of the other elements referred to it; but at present there is a decided movement in favour of the adoption as standard of an atomic weight which can be determined with more rigid accuracy than that of hydrogen can.

Although hydrogen is usually classed amongst the non-metallic elements, it is in its chemical behaviour more closely related to the metals. It combines with oxygen, at a red heat forming water, this combination being accompanied by the giving out of a great deal of heat. A jet of hydrogen burns in air or oxygen with a non-luminous flame, which is, however, sufficiently hot to heat to whiteness a fine platinum wire held in it. The behaviour of hydrogen towards chlorine is extremely interesting. The two gases can be mixed

in equal volumes and preserved without combination taking place for an indefinite period if kept in the dark, but on exposure to diffused daylight combination begins, and its progress depends upon the brightness of the light and the duration of the exposure. Momentary exposure to direct sunlight causes combination to take place with explosive violence, and a similar effect is produced by raising any portion of the mixture to a red heat. Hydrogen as a rule combines with those things with which the metals in general combine, forming compounds which are analogous to those of the metals. Compounds containing hydrogen and one other element are common decomposition products of decaying vegetable and animal matters; as, for instance, marsh-gas, ammonia, and sulphuretted hydrogen, which contain hydrogen combined with carbon, nitrogen, and sulphur respectively.

Hydrogen gas, under the name of combustible air, was obtained in the 16th century by Paracelsus by treating certain metals with dilute acids, and was more or less known to Boyle and others; but Cavendish (q.v.) in his paper on 'Factitious Airs,' published in the *Transactions of the Royal Society* for 1766, was the first to describe accurately the properties of this gas, and the methods of obtaining it, hence he is usually mentioned as its discoverer.

The ordinary methods for preparing and purifying hydrogen will be found in any elementary treatise on chemistry. See GASES.

Hydrogen Peroxide (sym. H₂O₂) is a compound of hydrogen and oxygen, containing a larger proportion of oxygen than water, the other compound of these elements. It was discovered in 1818 by Thénard, and was by him regarded as oxidised water as it very readily decomposes, when heated, into oxygen and water. The substance, when freed from water as completely as possible, is a thick transparent liquid, of specific gravity 1.45, without colour or smell, but possessing a bitter taste. It bleaches many vegetable colours, and when applied to the tongue or skin produces a white spot and gives rise to considerable pain. Its bleaching action and most of its chemical characters depend upon its powerfully oxidising properties. It is employed, in dilute solution, for the restoration of oil-paintings, its action upon these being an oxidising one.

Hydrography, as a branch of physical geography, deals with the waters of the globe in so far as they are available for navigation. The hydrographer determines by means of observations and soundings the outline of coasts and shores, the configuration of river-beds, lake-basins, and the seabottom adjacent to coasts, ascertains the position and extent of shoals and rocks and islands, as well as of beacons and lighthouses, investigates the nature and velocity of currents, the local tidal phenomena, the changes taking place in river-mouths and in harbours, and the alterations effected in coast-lines by the action of the sea. All these details it is his business to embody, as far as may be, in charts and maps which shall be serviceable for the practical mariner. See CHART.

Hydroid. See HYDROZOA.

Hydromechanics, a term sometimes used so as to cover what in this work is dealt with at Hydrodynamics (q.v.) and Hydrostatics (q.v.), as also hydraulics, or the department of engineering which deals with the application of liquids in motion to machinery. Hydromechanics is sometimes limited to the latter department alone. On the other hand, hydraulics is sometimes made to cover hydrodynamics. See ENGINEERING, with articles there cited, and WATER-WORKS, SEWAGE.

Hydromel, a beverage made of honey and water; fermented, it becomes mead.

Hydrometer, an instrument which indicates, by the depth to which it sinks in a liquid in which it floats, the specific density or specific gravity of that liquid. See SPECIFIC DENSITY.

Hydromys, a genus of water-mice found in Australia, Tasmania, and New Guinea, distinguished from all other rodents by the small number (27) of molars. They are called Beaver-rats in Tasmania; are nocturnal and very shy; inhabit the banks of both fresh and salt water, and swim well, with the help of partially-webbed hind-feet. The largest species is twice the size of a common rat. One species has the belly white, the other yellow.

Hydropathy, like *Hydrotherapy* and *Hydrotherapeutics*, means the use of water in the treatment of disease, or in the prevention of the tendency to disease. Popularly, however, *hydropathy* has become so attached to a special scheme of water treatment that it will be used here in that sense alone; while *hydrotherapy* will refer to the less restricted and more scientific use of water as one of the many therapeutic weapons furnished by experience to the armoury of the practitioner of medicine. Water is the world's natural medicine. We find early mention of water as a curative agent, and its virtues are extolled by many of the classical writers—e.g. Hippocrates, Galen, Celsus, Musa, and Asclepiades. In the middle ages Aetius, Alexander of Tralles, Paulus of Aegina, and Avicenna may be claimed as its advocates; while in more modern times Cudamus, Hollman, Bernardo, Sir John Floyer, Dr Baynard, the Hahn, Tissot, Dr Smith, and Hamecke deserve mention; as do also Pare, Lombard, and Percy in special reference to its use in surgery. By most of these men water was applied both externally and internally—internally chiefly as a cold drink in fevers; and it was on this point the battle raged chiefly, Boerhaave and others disputing hotly against the propriety of so administering it. To Dr James Currie (q.v.), a Liverpool physician, belongs the credit of introducing its use in fevers and febrile diseases. His book (1797) contains some most interesting information, and the records of a large number of experiments carried out to the best of his abilities, with the very imperfect thermometers then in use. His interest appears to have been originally roused by the success of Dr Wright in treating fever, both in his own case and that of others, on board ship, by the application of cold sea-water. Currie's work was translated into German by Michaelis, and spread his treatment far and wide, meeting with much favour and also with bitter hostility. Amongst its warmest supporters was Oertel, a teacher in Ansbach, who re-edited, or rewrote, many of the older treatises, and who probably had some direct influence on the man who really introduced a new era in treatment by water. This was Vincent Priesnitz (1732-1815), a Silesian farmer of Grafenberg, who after considerable success in treating wounds and sprains in animals with cold-water bandages, had to treat himself, a horse having broken some of its ribs. Again successful, he continued the treatment whenever he could on any of the neighbouring peasants, and advanced the further step of using water internally; his fame spread, and he soon gathered an immense *clientele* and achieved remarkable success. He showed great ingenuity in orienting, with the assistance of his patients, all sorts of new methods of applying water to every part of the body; and, though using water as his sole remedial agent, he very sagaciously employed hard exercise, fresh air, and a regulated plain diet as adjuncts. Unfortunately, being utterly ignorant of medicine, he taught peculiar ideas of disease, which he considered to be due to the presence in

the blood of certain acrid humours which had to be diluted and extracted by means of water. He said the escape of these produced an eruption which marked the crisis; but as it is known that water applied continuously will produce such an eruption on even the healthiest skin, and as all the known facts of pathology are opposed to his doctrines, we are obliged to reject his theories even while his practice is admitted to be admirable. It is to this special system of water treatment that the term *Hydropathy* is now generally applied. There are, however, endless hybrid varieties in which one or other theory, or particular form of practice, is either specially rejected or adopted; so it must not be supposed that the foregoing statements apply absolutely to all hydropathists. Beyond civil, however, the most scientific position to take up is that in which water is used as a remedial agent in every way, in which it has been proved to be useful, without restricting its use, or reading its results in the light of any theories, while at the same time care is taken to avoid all ill effects. This constitutes the system of *Hydrotherapy*, which obtains prominent notice in all modern books on therapeutics. Possibly the term might be improved, as heat in many cases seems to be the real agent, of which water is only the vehicle. Thermo-therapeutics and Thermo-therapy have been suggested as terms more scientifically correct. Water has often been abused, like every other good thing in this world; even an ice-water dyspepsia, due to too free indulgence in drinking iced water (but especially along with food), being not uncommon in America.

Water may be employed medicinally both internally and externally in its three forms—solid, liquid, and gaseous. For the external uses, see BATH; for its internal use with drugs in solution, see MEDICINE, and MINERAL SPRINGS. There is left for consideration here only its use internally as pure water. Absolutely necessary to the digestive process, it is essential to life, and requires rules for its advantageous use. Too large a quantity impairs digestion by so diluting the gastric and intestinal juices as to render them comparatively inert. The difficulty is to lay down definite rules for the right quantity, as this will vary with each individual in different surrounding circumstances, of temperature, amount of exercise, and quality and quantity of food. Personal experience and skilled advice must decide the quantity in each case.

As a general rule it is better to drink water about an hour before meals, as the gastric juice is then being prepared, and fluid will be thus supplied when most required. Every one with a weak digestion ought certainly to do this, and only drink a little *hot* water with food, as the stomach requires a considerable temperature to allow its physico-chemical reactions to be carried on successfully. Water is also very useful early in the morning and late at night as helping to flush out the stomach and bowels, dissolving and carrying off the waste materials which may have accumulated by the kidneys, lungs, and skin, the functional activity of which organs it much promotes. Where the evacuating power of the lower bowel is weak, or when piles are present, large injections of water, hot or cold as judged proper, are useful in clearing out the rectum and stimulating its coat. Ice internally or externally is very useful in checking hemorrhage and soothing irritability, as shown by vomiting or otherwise. As steam water is very useful in all forms of inflammation and irritation about the mouth, throat, or lungs, and often in such cases medication with various drugs increases its powers.

There are fifty hydropathic establishments in England, fifteen in Scotland, and only one in

Ireland. Most of these originally started with a full equipment for treatment, including a resident physician, bath attendants, and a complete set of baths; but many of the establishments now are merely high-class country boarding-houses. In a few, however, the hydropathist can still find all the usual requisites for correct hydropathic treatment. Amongst the best known of the old-fashioned houses are Smedley's at Matlock Bridge, Ben Rhydding, Hkley Wells House, Malvern, and Southport in England; Cluny Hill near Forres, Bridge of Allan, Melrose, Rothesay, and Crieff in Scotland; and St Ann's Hill near Cork, in Ireland. Among the magnificent modern establishments we may name those at Bath, Bournemouth, Buxton, Harrogate, Clverston, Windermere, The Hall at Bushey near Watford, Moffat, Peebles, Pitlochry, Shandon, Dunblane, Craiglockhart near Edinburgh.

See Claridge, *Old Water Cure* (1841); Graham, *Griffenberg* (1843); works on the Water Cure by Gully (1842-63), Johnson (1843), East (1850), Dunlop (1873), Smedley (1879), Braam (Eng. trans. 1875), and in German by Munde (1877), Runge (1879), Anjel (1886), with other works cited in the thirty pages of bibliography appended to Dr Winternitz's article on 'Hydrotherapeutics' in Von Ziemssen's *Handbook of General Therapeutics* (vol. v. 1886).

Hydrophis. See SEA-SNAKE.

Hydrophobia (Gr. *hydro*, 'water,' and *phobos*, 'fear') is a symptom of a disease known as Rabies, which may occur in man and in various animals; but the word hydrophobia is also frequently used to denote the disease itself. It has long been known that rabies is communicated from one animal to another if the saliva of the one is introduced into the organism of the second; whether it be the case that the first has bit the second, or has only licked it on an open sore. The saliva of a rabid animal produces no injurious effect if brought in contact with the unbroken skin of an animal, or even with a mucous surface, provided it be not exoriated. The dog is the animal most frequently affected by rabies.

When a rabid dog bites another animal the latter shows no immediate symptoms of disease. The wound caused by the teeth of the dog behaves like an ordinary wound and becomes cicatrised in the same manner. After the lapse of a certain period, which may vary from nine or ten days to several months (cases are known where the time has been as long as twenty-six or twenty-eight months), but is generally from four to six weeks, the animal that was bitten exhibits special symptoms; rabies has declared itself. The time that has lapsed since the bite was received is called the period of incubation. When the affected animal is a man, the first symptom is usually a change of character; he becomes melancholy and distrustful. Next, generally at the beginning of the case, appears a symptom called *aphobia*—the slightest breath of wind which touches the skin of the face causes its muscles to contract. Next comes hydrophobia—if the sufferer is offered anything to drink, his throat contracts, and he suffers spasms of the pharynx. When this symptom appears the death of the sufferer is at hand, and is certain to occur in two or three days. During the interval between the appearance of the hydrophobic symptoms and death the patient has periods of calm and accessions of fury, and also exhibits paralytic symptoms which usually commence in the lower limbs.

Rabies is therefore communicated by biting from one animal to another; any scratch made by the teeth of the affected animal is harmless unless the saliva is conveyed to the wound. The animals liable to be affected by rabies are very numerous,

and comprise almost all the mammalia—men, dogs, cats, horses, cattle, sheep, wolves, foxes, deer, &c.

The question of the etiology of rabies has remained very obscure until a very recent date; the most contradictory opinions were current when M. Pasteur in 1880 set himself to study this malady. His labours justify the following statements:

Rabies is a virulent disease, transmissible from one animal to another by the inoculation into the latter of those various secretions and tissues of the affected animal in which the virus dwells. This virus consists of a living organism which has not yet been made visible, by reason of the insufficiency of microscopic apparatus, but its existence can nevertheless not be denied. This statement, taken in connection with the results of M. Pasteur's labours in regard to the impossibility of Spontaneous Generation (q.v.), utterly contradicts the assertions of those who pretend to have observed rabies in animals which have never come into contact with rabid animals. Such assertions are always based on incomplete observations. If rabies could arise spontaneously in dogs, how can we explain the fact that vast regions like Australia may be wholly exempt from this scourge in spite of the great number of dogs there? The reason is that in these countries they most energetically prevent the introduction of any dog that can be suspected of rabies. If there were conditions under which rabies might spontaneously appear in dogs, then in territories so vast as the Australian colonies these conditions would certainly be realised from time to time. But there is no rabies in Australia.

M. Pasteur has studied the distribution of the virus in the individuals affected. He has observed that the virus was found in the nervous system and in the saliva, but not in the blood, the lymph, &c. Hence, if we inoculate another animal with the blood of a rabid beast, the first will remain wholly free of any rabid infection. Similarly, rabid virus introduced directly into the circulatory system of an animal will not produce rabies. But there is a sure means of communicating rabies from one animal to another—viz. by the introduction under the dura mater, on the surface of the brain, of a liquid which has first been sterilised and in which thereafter there has been soaked a portion of the central nervous system of the rabid animal. By this operation one is absolutely certain to communicate rabies unless the animal is refractory to rabies and cannot take the disease. In the course of his studies M. Pasteur observed that, in certain groups of animals which had been inoculated beneath the skin with large quantities of rabie virus, some not only did not take rabies, but became incapable of taking it—i.e. they might with impunity be inoculated on the surface of the brain with rabie virus. This observation was the origin of the discovery of preventive inoculation—of inoculation which renders an animal refractory to rabies.

The principle of such inoculation is as follows: The spinal cord of a rabbit which has died of rabies, when extracted from the body of the creature, and preserved in dry air at a constant temperature of 23° to 24° C. (74° to 76° F.), loses by slow degrees its virulence. With a spinal cord which has been so preserved for fourteen days it is impossible to communicate rabies to a rabbit or a dog. But this spinal cord has nevertheless still a certain power to confer immunity from the disease—the inoculation of an animal with a sufficient quantity of it will render it refractory to rabies. At the same time M. Pasteur observed that the freshest spinal marrows, that is to say, the most virulent, are those best fitted to confer immunity from infection. To render an animal refractory to infection the treatment commences by inoculating it with spinal cord fourteen days old, then with that of thirteen days, and so

on till spinal matter three days old is reached, two days, one day, and even such as is not yet one day old. The last may be introduced into the subject of experiment without danger, because it is already refractory.

What gives this discovery an enormous value is that these preventive inoculations made on an animal early enough and swiftly enough *after* it has been bitten prevent rabies from declaring itself. This is explicable on the following grounds: The virus is deposited by the dog's bite in a superficial wound; there it meets with little nerve-filaments in which it is further cultivated, and by means of which it ascends, somewhat slowly, to the nervous centres. These nerve-centres are the quicker affected the nearer to them the bite has been inflicted: hence bites on the head produce rabies after a shorter period of incubation than bites on the extremities of the body. If there is time to render the organism refractory by means of the preventive inoculations before the nerve-centres are affected the victim is saved; the nerve-centres once affected and destroyed, it is evident that no power of man can bring about a cure.

What ought to be done when any one is bitten by a mad dog is this. The wound made by the dog's teeth should be cauterised as soon as possible, and deeply too, so that if possible the virus may be destroyed before it has begun to cultivate itself in the nervous system. Then, if it is certain that the animal which inflicted the bite is mad, or if there is good reason so to believe, the victim should be sent as speedily as practicable to the nearest 'Anti-rabies Institute.' It is obvious that his safety depends on the quickness with which this is done. It is also obvious that bites on the head are more serious than bites on the limbs, inasmuch as there is a shorter distance to be traversed ere the nerve-centres are reached.

How can one make sure that the biting dog is mad? If possible the dog should be kept under observation without being killed; for it is much easier to recognise rabies in a living animal than by the earliest post-mortem examination. The animal will change its character, will often cease to eat, will bite everything within its reach, and will sometimes show signs of paralysis, its hind-quarters and its lower jaw being first attacked. In such cases the animal will inevitably die in from three to four days, or at most in eight days. A post-mortem examination will show the stomach empty of food, and containing on the contrary foreign substances such as bits of wood, stones, straw, &c. The most certain way of discovering if a dog was really mad is to introduce by way of inoculation a portion of its medulla under the dura mater of a rabbit. The rabbit will inevitably become rabid if the dog was rabid, but this will not take place till after fifteen or eighteen days; so that it would be imprudent for a person who had been bitten to await the result of the experiment before beginning to undergo preventive inoculation.

Statistics of the proportion of deaths by hydrophobia had never been properly kept up to the time of M. Pasteur's work in this department. Few doctors actually knew this terrible malady. It is generally said that of a hundred persons bitten by mad dogs some nineteen or twenty die of hydrophobia. This figure is probably too low. The mortality amongst cases treated at the Pasteur Institute (established by him in Paris in 1886) has fallen to less than $\frac{1}{2}$ per cent.

[So far M. Pasteur has sketched his discoveries and practice in regard to rabies, but a brief unargumentative review of current adverse criticism is also requisite. (1) As a working hypothesis, Pasteur assumes the occurrence of a specific microbe of rabies, which (in spite of various sanguine in-

vestigators) has not yet been demonstrated. In default of this demonstration, it seems to many that both the practice and the theory of rabie inoculation lack security and conclusiveness. (2) Again, there are some who, while believing vaccination to be empirically justified, are dissatisfied with the warrant for the anti-rabies treatment. They urge the acknowledged divergence between the two methods, and criticise the principle on which Pasteur works. (3) As to the warrant furnished by Pasteur's results, it is argued that the statistics are unreliable—e.g. because many of the patients inoculated were probably never infected, because in genuine cases the prevention may have been due to preliminary cauterising and to factors apart from the anti-rabies inoculation, and for various other reasons which forcibly suggest that in drawing inferences from statistics the sources of error are indeed numerous. (4) Less useful criticism is that which emphasises what is often true of progressive medical investigation—namely, that there have been failures in Pasteur's treatment, that certain tentative measures were confessedly futile, that there have been striking changes of method, and so on. (5) More serious is the allegation that some deaths have occurred as the result of the inoculations rather than of the infection from the rabid animal. Of such not altogether unprecedented casualties the possibility, but not the actual occurrence, was admitted by the English Investigation Committee (1887), while Dr Armand Leffler, who speaks with much authority, denies (1889) with all deliberateness that there is any case on record in which it can be proved that death has followed as the result of Pasteur's treatment. (6) The anti-vaccinationists have urged against certain implications of Pasteur's procedure various considerations which merit careful discussion, though without special bearing on the present problem. (7) So, too, the thorough-going anti-vaccinationists are of course among the critics of Pasteur, but their arguments can best be dealt with in connection with vaccine inoculation, about which we know at least a little more than we do in regard to the anti-rabies preventive (see VACCINATION). (8) Though there is much to be said on both sides, those who are willing to leave the problem to the experts will believe ineantine that Sir James Paget, T. Lauder Brunton, George Fleming, Sir Joseph Lister, Richard Quain, Sir Henry E. Roscoe, J. Burdon Sanderson, and Victor Horsley had good reasons for saying in the Report which they presented to parliament in 1887: 'It may, hence, be deemed certain that M. Pasteur has discovered a method of protection from rabies comparable with that which vaccination affords against infection from smallpox.'

In 1889 a Mansion House Fund was raised in London to enable poor English sufferers to be taken to the Institute; but like every other recognition of Pasteur's method, the scheme was reviewed with keen hostility by anti-vaccinationists and anti-vaccinators. In 1896 Dr Paul Gibier, a pupil and assistant of M. Pasteur, opened a Pasteur Institute in New York.

See Report of a Committee on M. Pasteur's Treatment of Hydrophobia, presented to parliament, 1887. For good summaries of Pasteur's method, see Dr E. Roux, Croonian Lecture, *Proc. Roy. Soc.* xlvii, (May 1889); Dr A. Kuller, *Brit. Med. Jour.*, (September 1889); Vignat, *Brit. Med. Jour.*, (April, May, 1886). See also papers by Pasteur in *Comptes Rendus Acad. Paris*, in *Bulletin de l'Acad. de Med.* (from 1881 onwards), in the *Annales de l'Institut Pasteur*, and in the *Ann. Révues* (X number 1889). See also Louis Pasteur, *his Life and Labours*, by his son-in-law (trans. by Lady Glad Hamerton, Lond. 1885). Of works published before Pasteur's discoveries, it must suffice to mention that of Channing. For criticisms of Pasteur, reference may be

made to publications of the Anti-Vivisection societies (especially Victoria Street, London), to papers by Dr A. Lutaud in the *Journal de Médecine de Paris*; Dr T. M. Dolan, *M. Pasteur and his Methods: a Critical Analysis* (Lond. 1886); Dr C. W. Dulles, *Medical Record* (New York, 1886); Dr M. Biggs, *The Medical News* (Philadelphia, 1886).

Hydrophyllaceæ, a natural order of herbs and bushes, containing about eighty known species, natives chiefly of the colder parts of America. None of them are of importance; but some of them are favourite ornaments of flower-borders, particularly different species of *Nemophila*.

Hydrostatics treats of the equilibrium of liquids, and of their pressures on the walls of vessels containing them. It is a purely dynamic science, and concerns itself virtually with only two of the many physical properties of liquids. These are density and mobility. In virtue of the latter property, a liquid has no tendency to conserve its shape, so that if a distorting force acts on it it yields without any tendency to recover. It has no Elasticity (q.v.) of form. Viscosity (q.v.) may retard the rate at which the distorting force takes effect; but a liquid will continue to change form so long as there is a force acting on it which is not balanced by a perfect reaction. Thus, in hydrostatic problems, nothing of the nature of a distorting force is taken into consideration. All pressures acting on portions of the liquid must therefore be perpendicular to the surfaces on which they act; and equilibrium requires equality of pressure in all directions at any point.

The fundamental property may be thus stated: When a pressure is exerted on any part of the boundary of a liquid at rest, that pressure is transmitted undiminished to all parts of the mass and in all directions. Most of the other propositions of hydrostatics are only different forms or direct consequences of this truth, which may be proved experimentally. Suppose a close box B to be filled with water, and to have inserted into the upper cover a tube *a*, with closely-fitting plug or piston, 1 square inch in area. If the

Fig. 1.

plug *a* is now pressed down upon the water with a force equal to a pound weight, the water, being unable to escape, will react upon the piston with the same force; but it obviously will not press more against *a* than against any other part of the box, therefore every square inch of the interior surface of the box is pressed outward with the force of a pound. If, then, there is another tube inserted in any part of the box with a plug of the same area, as at *b*, it will require a force of a pound to keep this plug in its place. (We leave out of account at present the pressure upon *b* arising from the weight of the water in the box above it—i.e. we neglect gravity and consider only the pressure propagated by the forcing down of the plug *a*.) However many plugs of the same size there may be, each will be pressed out with the same force of a pound; and if there be a large plug of four times the area, as at *c*, it will be pressed out with a force of four pounds. We have only, then, to enlarge the area of the piston *c* to obtain any multiplication of the force exerted at *a*. If the area of *c* is 1000 square inches, that of *a* being 1 square inch, a pressure of one pound on *a* becomes a pressure of 1000 pounds on *c*; and if we make the pressure on *a* one ton, that on *c* will be 1000 tons. This seemingly wonderful multiplication of power has received the name of the

hydrostatic paradox. It is, however, nothing more than what takes place in the lever, when one pound on the long arm is made to balance 100 pounds on the short arm.

If the pressure supposed to be exerted on the piston *a* arise from a pound of water poured into the tube above it, it will continue the same though the piston be removed. The pound of water in the tube is then pressing with its whole weight on every square inch of the inner surface of the box—downwards, sideways, and upwards. The apparatus called the *hydrostatic bellows* acts on this principle (see fig. 2). It consists of two stout circular boards connected together by leather in the manner of a bellows, B. The tube A is connected with the interior; and a person standing on the upper board, and pouring water into the tube, may lift himself up. If the area of the upper board is 1000 times that of the tube, an ounce of water in the tube will support 1000 ounces at W. It is on the same principle that the Hydraulic Press (q.v.) depends.

Fig. 2.

(1) *Equilibrium of Liquids*.—After this explanation of the fundamental properties of liquids it may be enough to state the two conditions of fluid equilibrium which directly flow from it. (1) Every particle of the liquid must be solicited by equal and contrary pressures in every direction; otherwise there would be a tendency to motion, and therefore motion because of the liquid property of mobility. (2) The upper particles at the free liquid surface must form a surface perpendicular to the impressed force. The truth of this is experimentally demonstrated by the horizontality of the surface of a liquid at rest under gravity. It can be shown to be a consequence of the primary property of 'pressing equally in all directions,' for let *da* and *cb* be vertical lines, or lines in the direction of gravity; and *ab* a plane at right angles to that direction, or horizontal. A particle of the liquid at *a* is pressed by the column of particles above it from *a* to *d*; and the like is the case at *b*. Now, since the liquid is at rest, these pressures must be equal; for if the pressure at *b*, for instance, were greater than

Fig. 3.

at *a*, there would be a flow of the water from *a* towards *b*. It follows that the line *ad* is equal to *bc*, and hence that *dc* is parallel to *ab*, and therefore horizontal. The same might be proved of any two points in the surface; therefore the whole is in the same horizontal plane.

(2) *Pressure of Liquids on Surfaces*.—The general proposition on this point may be stated thus: The pressure of a liquid on any surface immersed in it is equal to the weight of a column of the liquid whose base is the surface pressed, and whose height is the perpendicular depth of the centre of gravity of the surface below the surface of the liquid (see CENTER OF PRESSURE). The pressure thus exerted is independent of the shape or size of the vessel or cavity containing the liquid.

(3) *Loss of weight and Flotation*.—As a consequence of the proposition regarding the pressure of liquids on surfaces it can be shown that when a solid body is immersed in a liquid its loss of weight is equal

to the weight of the displaced liquid—i.e. to the weight of an equal bulk of liquid. Thus, if a cubic foot of the liquid weighs the same as a cubic foot of the solid, the solid will appear to have lost all its weight, and will remain in the liquid wherever it is put; if a cubic foot of the liquid weighs less than a cubic foot of the solid, the solid will appear to lose part of its weight, and will sink; but if a cubic foot of the liquid weighs more than a cubic foot of the solid, the immersed solid will not only lose all its weight, but will appear to be dominated by a *negative* weight, being urged upwards to the surface of the liquid by a force equal to the difference of the weights of the displaced liquid and the solid. In this last case the solid will rise until it swims or floats on the surface of the liquid, the amount of solid immersed in this

Fig. 4.

final state of equilibrium being determined by the obvious principle that a floating body must be buoyed up by a force equal to its own weight. Here again, then, the solid seems to lose all its weight, which loss must be simply the weight of the displaced water. Thus in fig. 4, where AB represents a floating solid, the water displaced by the immersed part B is equal in weight to the whole solid.

As the buoyancy of a body thus depends on the relation between its weight and the weight of an equal bulk of the liquid, the same body will be more or less buoyant, according to the density of the liquid in which it is immersed. A piece of wood that sinks a foot in water may sink barely an inch in mercury. Mercury buoys up even lead. Also a body which would sink of itself is buoyed up by attaching to it a lighter body; the bulk is thus increased without proportionally increasing the weight. This is the principle of life-preservers of all kinds. The heaviest substances may be made to float by shaping them so as to make them displace a volume of water greater than the bulk of their own solid substance immersed. A flat plate of iron sinks; the same plate, made concave like a cup or boat, floats. It may be noted that the buoyant property of liquids is independent of their depth or expanse, if there be only enough to surround the object. A few pounds of water might be made to bear up a body of a ton weight; a ship floats as high in a small dock as in the ocean.

(4) *Stability of Floating Bodies.*—Conceive *abd* (fig. 5) to be a portion of a liquid turned solid,

Fig. 5.

but unchanged in bulk; it will evidently remain at rest, as if it were still liquid. Its weight may be represented by the force *cg*, acting through its centre of gravity *c*; but that force is balanced by the upward pressure of the water on the different parts of the under surface; therefore, the resultant of all these elementary pressures must be a force, *cs*, exactly equal and opposite to *cg*, and acting through the same point *c*, otherwise the body would not be at rest. Now, whatever other body of the same size and shape we suppose substituted

for the mass of solid water *abd*, the supporting pressure or buoyancy of the water around it must be the same; hence we conclude that when a body is immersed in a liquid the buoyant pressure is a force equal to the weight of the liquid displaced, and acting in the vertical line through the centre of gravity of the space from which the liquid is displaced. This point may be called the *centre of buoyancy*.

We may suppose that the space *abd* is occupied by the immersed part of a floating body *abcd* (fig. 5). The supporting force, *cs*, is still the same as in the former case, and acts through *c*, the centre of gravity of the displaced water; the weight of the body must also be the same; but its point of application is now *c'*, the centre of gravity of the whole body. When the body is floating at rest or in a state of equilibrium, this point must evidently be in the same vertical line with *c*; for if the two forces were in the position of *cs*, *c'y* (fig. 6), they would tend to make the body roll over. The line passing through the centre of gravity of a floating body and the centre of gravity of the displaced water is called the *axis of flotation*.

A floating body is said to be in *stable* equilibrium when, on suffering a slight displacement, it tends to regain its original position. The conditions of stability will be understood from the accompanying figures. Fig. 7 represents a body

Fig. 7.

Fig. 8.

floating in equilibrium, *G* being its centre of gravity, *B* its centre of buoyancy, and *AGB* the axis of flotation, which is of course vertical. In fig. 8 the same body is represented as pushed or drawn slightly from the perpendicular. The shape of the immersed portion being now altered, the centre of buoyancy is no longer in the axis of figure, but to one side, as at *B'*. Now, it is evident, that if the line of direction of the upward pressure—i.e. a vertical line through *B'*—meets the axis above the centre of gravity, as at *M*, the tendency of the two forces is to bring the axis into its original position, and in that case the equilibrium of the body is stable. But if *BM* meet the axis below *G*, the tendency is to bring the axis further and further from the vertical, until the body get into some new position of equilibrium. There is still another case; the line of support or buoyancy may meet the axis in *G*, and then the two forces counteract one another, and the body remains in any position in which it is put; the body is then said to be in *neutral* equilibrium. In a floating cylinder of wood, for instance, *G* is always right under *B*, in whatever way the cylinder is turned. When the angles through which a floating body is made to roll are small the point *M* is nearly constant. It is called the *metacentre*; and its position may be calculated for a body of given weight and dimensions. In the construction and lading of ships it is an object to have the centre of gravity as low as possible, in order that it may be always below the metacentre. With this view, heavy materials, in the shape of ballast, are placed

in the bottom, and the heaviest portions of the cargo are stowed low in the hold. See SPECIFIC GRAVITY.

Hydrosulphuric Acid. See SULPHUR.

Hydrothorax derived from *hydro*, 'water,' and *thorax*, 'the chest' is the term applied to dropsical collections in the pleura. See DROPSY, PLEURISY.

Hydrozoa, one of the main divisions of the phylum or sub-kingdom Cœlenterata (q.v.), the other two being Ctenophora (q.v.) and Anthozoa or Actinozoa (q.v.). Two animal forms (zooïds), reducible to one common plan, are present, which often alternate in the life-history of the individual. Of one of these, the Hydroid or Polyp, the common fresh-water Hydra (q.v.), may be taken as the simplified type; the other is the Medusa or jelly-fish. It is only in this latter or in some degenerate form of it that sexual organs are produced (except in the case of Hydra). The Hydrozoa may be free

or fixed, simple or colonial, and these variations in habit, along with the existence of two kinds of zooïds just referred to, render their constitution so complex that it will be advantageous to describe briefly one or two typical forms before giving the systematic arrangement of the group.

In the case of *Sarsia* the egg produced by the jelly-fish develops first into an ovoid ciliated cellular larva (*planula*), which attaches itself to

Fig. 1.

a, *Sarsia* *fectiva* (redwood); b, branch of same (magnified 10x); c, *Sarsia* *medusa* of same, shortly after liberation. (After Allman.)

some solid object by one end, whilst the other grows into a polyp with mouth and tentacles, a colony being afterwards produced by budding. In the most essential points of its structure the Hydra may be regarded as the type of these polyps; the tentacles, however, are solid, and arranged in more than one circle; they have club-shaped ends beset with thread-cells. The name *Syncoryne* has been given to the polyps of this genus. Upon the walls of the expanded extremities appear buds, each of which, gradually enlarging and assuming the structure of a Medusa, drops off when ripe and leads an independent existence. It consists of a high bell, the mouth of which is partly closed by a circular veil attached round its margin. The clapper of the bell (*manubrium*) is long, cylindrical, and contractile, and has a mouth at its extremity leading into a stomach within its base, from which four canals radiate within the substance of the bell. At the margin of the bell they are united by a ring-canal, and beyond this they are produced into long hollow contractile tentacles. Near the origin of these from the ring canal are situated eyes, which are not merely sensitive to light, but capable of vision. A double nerve cord passes along the ring-canal, and sexual organs are developed in the wall of the manubrium. The inner and outer surfaces of the bell are covered with ectoderm, whilst the cavity of the stomach and the canals leading from it are lined with ciliated endoderm. There are ectodermal muscles in the sub-umbrella. The eggs produced by the process of sexual reproduction

develop into polyps and the whole life-circle is repeated.

In certain cases the Medusa or sexual person, instead of becoming free, has remained attached to the Hydroid polyp, and under such circumstances has undergone more or less degeneration. It may (1) present the principal structural features of a Medusa, except that it is mouthless, and that it has the form of a closed sac owing to the adhesion of the margins of the bell ('adoleoconic gonophore' of Allman), or (2) it may be merely a bud containing sexual products ('sporosac').

Aurelia aurita, one of the commonest jelly-fishes of our coasts, may be selected as an example of a Medusa of quite different structure. The bell is flattened, thickest in the centre, and notched round the margin. The manubrium is split up into four long pointed processes with fringed margins, and from the stomach and from its four sacular expansions there proceed eight unbranched canals, and eight which bifurcate several times, and are united by a marginal ring-canal. Four ring- or ear-shaped reproductive glands are developed in the base of the stomach, but hang down on the lower surface of the bell. In each of the eight marginal notches, which correspond to the main stems of the branched canals, is a so-called 'marginal corpuscle,' or sense-organ, containing an otolith and a pigment mass. These sense-organs appear to be nerve-centres, and, by their connection with a nervous plexus in the sub-umbrella, to control the movements of the animal: there is no closed nerve-ring. Between the marginal corpuscles are a large number of short tentacles. The egg gives rise to a ciliated planula, which, after swimming freely for some time, becomes fixed and gives rise to a polyp (*Scyphistoma*) which has at first four, then eight,

Fig. 2.—*Aurelia aurita* (reduced).

and then many tentacles. Four internal septa, reaching from the base to the margin of the mouth, divide the cavity of the polyp into a central space and four lateral recesses. Usually the polyp undergoes a series of transverse constrictions, which produce a series of Medusae, which are set free after the tentacles of the polyp have been absorbed. The organism in this stage is known as a Strobila. After a whole series of Medusae has been thus set free the polyp can form tentacles afresh, and the whole process can be repeated. The Medusae when first set free have neither arms, marginal tentacles, radial canals, nor reproductive organs, so that they have to undergo a complicated development in the free state.

The Hydrozoa are widely distributed, and all marine, with few exceptions (e.g. *Hydra*, *Caryophora*). The Hydroid polyps and colonies are attached to foreign substances, the Medusae and Siphonophora are free-swimming, in most cases near the surface, though certain forms appear to be denizens of deep water (*Pectis*, *Nauphanta*, *Rhodalia*). They are carnivorous, and some are beautifully phosphorescent (*Pelagia*, *Diphyes*). A few are fossil—e.g. the palæozoic *Graptolitidae* and

Stromatoporidae, and some Medusa from the Jurassic period, and some from the Chalk. There are about 1000 species, arranged under some 350 genera, which may be classified as follows:

1. *Craspedoia* (Hydrozoidae)—Hyroid form, either free and temporary, or free or fixed, simple or colonial, and permanent. Sometimes tentaculate, tentacles usually solid; mouth prominent, gastric cavity simple, skeleton usually chitinous, rarely calcareous. Asexual reproduction, usually by gemmation. Medusoid form, with tubular manubrium, and an inverted velum; sensory organs, ocelli, or auditory organs. It may become sessile and degenerate. Sexes separate. Almost all marine.

(1) *Trachymedusa* (Monopsea, Haplomorpha)—Free-swimming Medusa, with the gelatinous substance of the disc hard and stiff; no hydriform phase in development; tentacles primitively solid; auditory vesicles present. Examples: *Geryonia*, *Egona*.

(2) *Hydroidea*.—Hydriform person, with small polyps; generally colonial, with a chitinous (rarely calcareous) exoskeleton. Sexual only in Hydra. Medusiform person produced by gemmation from the hydriform, often degenerate. (1) Tubularia (Gymnoblastera, Anthomedusae), hydriform person usually colonial; no special receptacles for the polyps (these), or the medusiform buds (gonangia); sexual organs in the outer or oral wall of the stomach. Medusae have neither oocytes nor tentaculo-cysts, but ocelli at the bases of the tentacles; and are of the kind known as Anthomedusae. Examples: *Tubularia*, *Coryne*, *Cordyliphora*. (2) Campanularia, Caryophlastea, Leptomedusae, hydriform person in permanent colonies, with a single circle of solid tentacles; hydrothecae and gonangia usually present; medusiform persons belong to the division Leptomedusae, being flattened, having the velum feebly developed; tentacles 2, 4, 6, 8, up to several hundred, sometimes with ocelli at the base; auditory organs sometimes present; sexual glands in the radial canals. Examples: *Campanularia*, *Sertularia*, *Flombularia*. (3) Eleutherozoastera, colonies not permanent; no differentiated gonophores. Examples: *Hydra*, *Procyona*. (4) Hydrocorallia, skeleton calcareous, containing the Stylasteridae and the Milleporidae (q.v.). (5) Rhadophora, containing certain Cambrian and Silurian fossils known as Graptolites, q.v.

(ii) *Siphonophora*, Pelagic colonies, with several different kinds of modified polyps or Medusae (see special article).

II. *Acraspeda* (Acalyptra, Scyphomedusae).—Medusae, generally of considerable size, with lobed margin, bearing sensory spherules; manubrium square, usually produced into prolonged angular lappets; no velum; the sexes are separate; nervous centres in the marginal sensory bodies. Hyroid form known in but few instances; small and fixed, mouth surrounded by a disc, provided with six or more solid tentacles; multiplies by lateral buds on a creeping shoot; Medusae formed from it by transverse fission. All marine.

(1) *Tessaronia*.—Umbrella high, parts disposed in fours, four gastric pouches. (1) Stauromedusae, without sensory bodies. Example: *Lucernaria*. (2) *Promedusae*, with four sensory bodies, disposed between the principal radii. (3) *Cubomedusae*, with four sensory organs, placed in the principal radii, four simple tentacles, and eight marginal pouches. Example: *Charybdea*.

(ii) *Ephyrae* (Discomedusae). Umbrella flattened, parts disposed in eights. (1) *Rhizostoma*, no central mouth, numerous suboral apertures on eight long root-like arms; no tentacles. Example: *Cranchia*. (2) *Semostoma*, four long arms surrounding a simple cruciform mouth. Example: *Aurelia*. (3) *Cannostoma*, no arms round the mouth, which is square; tentacles solid, usually short. Example: *Nau-stome*.

In addition to text-books of Zoology in general, the following works may be consulted: Forbes, *Monograph of British Naked-eyed Medusae* (Ray Society, Lond. 1848); Agassiz, *North American Acalyptra* (Camb. U.S.A. 1865); Hincks, *British Hydroid Zoophytes* (1868); Allan, *Monograph of Gymnoblaster Hydroids* (Ray Society, 1872); *Report on the Hydroidea* (Challenger Reports, *Zoology*, parts 20 and 70, 1883 and 1888); Claus, *Untersuchungen über die Organisation und Entwicklung der Medusen* (1883); Haackel, *System der Medusen* (1879-81); *Diphysea Medusae* (Challenger Reports, *Zoology*, part 12, 1882; Lendenfeld, *The Australian Hydro-medusae* (1885) and other papers.

Hyères, a town of Provence, in the French department of Var, on a southern hill-slope, crowned by a ruined castle, 3 miles from the Mediterranean, and 13 E. of Toulon by rail. Embosomed in palm groves and orange-orchards, it is celebrated for the beauty of its situation and its mild, dry climate, and is therefore growing more and more in favour as an invalid resort between October and May. An English church was built in 1884; and since 1875 great improvements have been carried out in the way of drainage, water-works, boulevards, &c. Massillon was a native. Pop. (1872) 5881; (1891) 8347. Near the coast lie

the wooded Îles d'Hyères or d'Or (anc. *Stoechaides*). Here the heat of the climate is tempered by the sea-breezes, and the season seems an eternal spring. See Denis, *Hyères, ancienne et moderne* (4th ed. Hyères, 1882).

Hyetography. See RAIN.

Hygieia, in classical mythology the goddess of Health, was the daughter of Esculapius. She was worshipped at Athens, Corinth, Argos, and other important cities, and in works of art is usually represented as a virgin, with a snake, the symbol of health, which drinks from a cup held in her hand.

Hygiene is the name given to that department of inquiry which deals with the causes and prevention of disease in their relation to the preservation of health. As thus defined, hygiene, while it is founded on medical experience, and while it is advanced by medical research, stands out clear and defined from the ordinary run of the science and art of medicine which deal with the cure of disease. The aim of hygiene is to prevent disease by the due appreciation of the causes which induce a departure from the normal type of healthy life. In this sense it has well been named Preventive Medicine, since it seeks to anticipate the work of the physician by its endeavour to remove the causes on which the diseases that affect mankind depend. Hygiene presents for consideration two chief phases. The first section of *Personal Hygiene* relates to the individual as a unit and to his duties in the maintenance of health, and in disease prevention. The second section deals with *Public Health*, and concerns the relations which exist between masses of men and the conditions of healthy living. In the first case the study embraces such subjects as food, clothing, habits, heredity, and the like, which relate to the personal history of the unit. In the latter case hygiene has to regard the community and the nation, and to investigate the laws under which disease is liable to be propagated by the circumstances of collective life. The departments of hygiene which deal with drainage, healthy houses, the removal of waste, and the prevention of infectious disease illustrate the subjects with which the public sanitarian or health officer concerns himself. It is of importance, however, to note that, as regards these two aspects of hygiene, their scope is by no means so restricted and so limited as the terms of their definition might seem to imply. For public health, as may readily be shown, can only be advanced by the endeavours of individuals. It is the individual and personal culture of health which not only must precede, but which also forms the foundation of public sanitation.

The history of hygiene forms in itself a study of much interest, and teaches us that, like most other branches of modern science, that of health has exhibited a gradual evolution and a cumulative advance. Very far back in the history of mankind we may trace the presence of the ruling idea of hygiene, that disease could be prevented by attention to the laws and conditions of healthy living. That the hygienic codes of the Jews were remarkably full and complete is evident from a perusal of the Mosaic books of the Scriptures. These laws, dealing with questions of food and feeding, with the isolation of the sick, and with the removal from camps and dwelling places of waste matters, were of singularly enlightened character. The modern Jews have profited by the attention paid by their forefathers to questions of sanitation in the shape of their greater relative longevity, and their freedom from the scourges and plagues that have decimated the nations amidst which they dwell. The great desire of the ancient Jew

that his days might be long in the land, and that his race should grow strong and multiply exceedingly, bore a very evident relation to the practice of those health laws according to which immunity from disease is secured and longevity encouraged. So that early enough in the phases of human development and civilisation sanitary science began to be studied in view of its obvious effects upon both personal and national welfare. The Greeks may also be quoted as a nation given to make a special study of the conditions of healthy living; but in their case the culture of a high standard of physique probably included most, if not all, the points to which this ancient people paid attention. They entertained a lofty ideal of physical beauty, and attained this ideal undoubtedly through the practice of much that partook of the character of hygienic science. Apart from this bodily culture, however, the Greek was not a sanitarian in the true sense of the term. He was visited by epidemics and plagues, which were regarded as signs of displeasure on the part of his deities. He made no attempt to discover the causes of these scourges or to arrest their course. Sanitation in Greece of old was therefore more a thing of chance than of scientific nature; and of ancient Rome the same opinion may be expressed. Great public works, and most notably those connected with water-supply and drainage, were certainly undertaken and carried out on a scale of magnificence; and so far these measures must have aided in the maintenance of the public health; but plagues were frequent and loss of life excessive as in ancient Greece, and of the laws of health as we today understand that term the classic nations seem to have been nearly ignorant. Medicine itself was of course in its infancy; and for this reason—viz. the lack of knowledge of the causes or disease—the health of the ancients was largely a matter of chance.

The record of progress in health science naturally follows the course and track of ordinary history, and in this respect forms a most interesting comment on the social advance of the people. The middle ages with ourselves, for example, beheld personal health neglected and public health unknown. Cleanliness was conspicuous by its absence; the 'sanctity of dirt' was respected by priest and people alike; the houses were built closely together; their domestic appliances were of the rudest description; and drainage was non-existent. The conditions of ordinary existence were those of rapine and war, and under such circumstances it is not wonderful that the science which devotes itself to saving life should scarcely have made its influence felt at all. The clearest proofs of the utter neglect of sanitation were to be found in the fevers and plagues with the records of whose frightful mortality the story of the middle ages teems. Dr Guy, who made a special study of the history of the epidemics of the middle ages, tells us that in the 12th century no fewer than fifteen epidemics and many famines were recorded. The 13th century saw twenty plagues and nineteen famines; while the 14th beheld in its early part eight epidemics and a succession of famines. In 1348 came to England the Black Death or Great Pestilence. As the result of this plague, which attacked Europe from the East, 100,000 persons died in London alone. In Europe at large it was estimated some 25 millions of persons died from this plague. The Sweating Sickness attacked England in 1485. This was a plague which was apparently propagated within the bounds of our own land by the filthy and impure surroundings of the people. After being attacked by the sweating sickness, the victim usually died within twenty-four hours. It attacked

the well-to-do and intemperate livers especially, and appears to have been more fatal in the case of men than of women. After a succession of reappearances this epidemic passed away in 1551, and has since that date been extinct. A century or so later (in 1666) came the Great Fire of London, a catastrophe which was not an unmixed evil, since it cleared away the Old London with its foul and close houses, and induced the erection of a new and more sanitariously built city. The great fire apparently gave the *coup de grâce* to the Great Plague, which prior to 1666 had swept from time to time across the country, but disappeared in that year, happily to return no more. The cessation of the epidemic plagues thus enumerated was doubtless due to the abolition or modification of the conditions under which they had previously flourished. Less crowding together of people and of their dwellings, a freer atmosphere, and a greater measure of cleanliness doubtless acted then as now in abolishing epidemics; but even in the 18th century smallpox, typhus or jail fever, scurvy, ague, and other diseases continued to be only too well represented as legacies of the ignorant and careless living which characterised the preceding era.

It is, however, in the 18th century that hygiene begins to appear on the social horizon with something of clear outline and defined aims, as a distinct branch of science, pursuing a very practical relation to the lives of men. The Black Death and other plagues had then disappeared as we have noted, and thus the chances of prolonged life had become materially increased in Britain and in other European countries as well. The sanitary historian of the 18th century has to take account of at least three great names as those of forerunners in the work of hygienic progress. John Howard (q.v.), the philanthropist, largely based his work of jail reform on improvement in the terrible state of these places of detention. They were overcrowded, and filthy in the highest degree, and, as a consequence of these conditions, typhus fever (which is a disease of overcrowding) reigned rampant under the name of 'jail fever.' Howard by his unflinching efforts succeeded in clearing the jails of this pest; and to-day our criminals reap the fruit of Howard's philanthropy in the fact that the jail now ranks in reality as the healthiest of dwelling-places. It is no exaggeration to say that if our homes could be rendered sanitary to the same extent as are the jails of our land, the death-rate would be speedily reduced to a minimum compared with its present amount. Captain Cook, the navigator, stands out as the second of the sanitary pioneers of last century. He it was who first showed that scurvy, which is essentially a blood disorder, and from which whole ships' crews used to remain prostrate in long voyages, was due to improper feeding. In one of his voyages Anson lost 600 out of 900 men from scurvy. Cook in a three years' voyage lost only four hands out of 118, and not one of these four deaths was due to the seaman's pest. He showed that in the absence of fresh vegetables, lime-juice should be served out regularly to ships' crews (see SCURVY). To-day Captain Cook's discovery is duly acted upon in the case of long voyages; and the extinction of scurvy in this fashion may be regarded as parallel in importance to the prevention of ague through the draining of the swamps and morasses amid the decaying vegetation of which the ague germs breed and multiply.

The third discovery of importance in sanitation in the 18th century introduces us to a feature in disease prevention which demands especial notice, because of the renewed importance which the prin-

eiple in question has acquired in our own days. This feature may be called that of the *modification* of disease. It began, doubtless, far back in the history of eastern nations, if we are to credit Hindu records, but in 1720 Lady Mary Wortley Montagu, wife of the English ambassador to Turkey, introduced it to the notice of English physicians under the name of *inoculation*. This practice came into vogue as a preventive of smallpox in its pristine severity. Here smallpox matter, taken from the pustules of a person suffering from that ailment, was inoculated into the bodies of healthy persons. The result as a rule was that they acquired a mild attack of the disease, and this attack was found to prevent a future invasion of smallpox. Inoculation undoubtedly did not limit the spread of smallpox—indeed, as can be seen, it favoured its spread—but it undoubtedly tended to modify that loathsome ailment, and to prevent the dreaded scars and deformities which resulted from the disease in its full vigour. Later on came Jenner's discovery of *vaccination*. This practice began about 1796. Here matter taken from the pustules of cow-pox was used to 'vaccinate' the human being, the result being that a mild attack of cow-pox (or allied disorder) was given to children, and this was found, and still is found, in the vast majority of cases to be preventive of smallpox. The subject of vaccination need not be discussed here; reference may be made to the article on that subject; suffice it to say that since 1840, when vaccination began to be made the subject of legal enactment in Britain, and since 1853, when free vaccination was provided for the poor by law, smallpox has decreased both as regards frequency and severity. In 1867 vaccination was made compulsory for infants, and at the present time, even if it has not effected a universal escape from smallpox attack, we may congratulate ourselves upon a tremendous saving of life from this disease by its aid.

The advance of medical science—and especially the progress which has been made in microscopic research into the causes of disease—together with the spread of education, and of a consequent intelligent interest in health science among the people, has tended powerfully to awaken national endeavour in matters both of personal and public hygiene. In Britain the law has stepped in, and has provided, by means of many suitable enactments (1848, 1875, &c.), full encouragement in the pursuit of healthy life, as well as protection against health dangers. Each town or district is provided with its medical officer of health, and with its sanitary inspectors, whose duties comprehend the abolition of nuisances and the general supervision of drainage and other sanitary details. To-day it may be said that we possess a very fairly equipped staff of health experts in every large town, able and eager to assist and advise the citizens in the discharge of their manifest duties to themselves and their neighbours in the observance of hygienic rules. One of the most important enactments, for instance, is represented by the law which in many towns makes compulsory the notification to the authorities of every case of contagious disease which falls under the notice of the householder or medical attendant or both. In this way it is sought to limit the spread of those infectious ailments which add so largely to the death-rate each year. The authorities, being early informed of the appearance of any cases of these diseases, can take prompt measures for their isolation and their removal, if need be, to hospital. One case of smallpox, of typhus fever, or of scarlet fever may readily become, by neglect, the parent of thousands of cases, with a probable mortality frightful to contemplate; whereas by prompt isolation of the

first case or cases misery, pain, loss of money, and chances of death may be saved to thousands. The seaports, too, are now narrowly watched by the health officers of these ports, and suspicious cases of illness on vessels arriving in harbour are at once dealt with. Cholera, it may be mentioned, which has run unchecked on the continent of Europe on several occasions within late years, has thus been warded off from the British coasts by the active supervision of the health authorities at the ports.

Within the sphere of the home health science has made of late years satisfactory progress. The principle of safe and sanitary drainage, whereby a house can be trapped off efficiently from the public sewers, and the inroads of sewer-gas (giving rise to typhoid fever and other ailments) prevented, is beginning to be everywhere practised. Plumbers are now encouraged to undergo examinations, instituted first of all by the Plumbers' Company of London, and to acquire thereby certificates of registration showing their knowledge of the principles on which house-drainage should be constructed. The vile 'scamping' work in the matter of drains so prevalent in former years, and so fraught with danger to the inmates of houses, it is to be hoped will be effectually banished from our midst. Here, as elsewhere, in sanitary science, the intelligent interest shown by the public in hygiene is beginning to bear fruit. The householder is no longer content to leave the sanitary arrangements of his house in the hands of ignorant architects or equally ignorant plumbers. His interest in his health affairs and his demand for sound sanitary work is a species of demand for which the inevitable supply is forthcoming in the shape of the increased attention now being paid to the construction of closets, baths, drains, lavatories, &c., and to the efficient protection of the house from the inroads of drain effluvia. In other details also the health of our homes is receiving the care it deserves. Questions of ventilation and of lighting are being studied anew, and the warming of houses is no longer left to chance. Personal health, which ranges in its extent from questions of foods and drinks to those of cleanliness and clothes, is not neglected amid the general improvement in hygienic education; so that the outlook in health questions is on the whole of the most hopeful kind. Happily the people at large are beginning at length to perceive and to act on the great truth that only by their personal education in hygiene, and by their knowledge and observance of health laws, can they secure the length of days which of old it was declared Wisdom bore in her right hand.

As a final point deserving of mention in relation to the acquirement of hygienic knowledge we may refer to the spread of knowledge regarding the exact causes of those infectious or zymotic diseases to which reference has already been made. These diseases include such ailments as smallpox, typhus fever, cholera, typhoid (or enteric) fever, measles, hooping-cough, diphtheria, scarlet fever, and like disorders. That they are responsible for a very large amount of our annual mortality is a stable fact, and it is interesting to note how the better knowledge of their causation bids fair to enable us to cope successfully with their attack. It is now generally admitted that each of these diseases arises from a specific living particle or *germ* which, sown in the body, under favourable conditions, gives rise to the disease in question. Each germ is derived from a previous case of the disease, and each disease, under ordinary circumstances, breeds true—that is to say, if we sow smallpox we reap smallpox, and not measles or scarlet fever; and so with every other disease. What is known as the 'germ theory of disease' has thus come to assume a paramount

place and power in modern hygiene. Already we have become acquainted with the specific germs of many disorders. We know, for example, the *Bacillus tuberculosis*, or germ to which tubercle is due—consumption or *phthisis* being merely a form of tubercle, as that disease affects the lungs. The germ of relapsing fever is also known, and that of the splenic fever of cattle and sheep has been very fully studied. The fight of mankind against these fevers and allied ailments is thus in reality a combat with the germs to which they owe their origin. All attempts to limit these disorders by disinfection or otherwise are directed towards the destruction of the germs which are given off from each case of a given disease, and which, if allowed to escape into air or water, infallibly spread the ailment broadcast. The knowledge of the exact origin of such diseases is therefore a powerful weapon in the hands of the sanitarian. In other ways than by germ-destruction it is sought to protect man and animals against disease attack. Pasteur and others, by modifying the germs of a disease (e.g. those of splenic fever) by submitting them to varied conditions of temperature, &c., and by artificially propagating them in appropriate solutions, have succeeded in producing germs of altered and weakened power. These later, used to inoculate animals, produce a mild form of the disorder, which protects against subsequent attack (see HYDROPHOBIA). This is the latest practical development of the germ theory itself. How far it may be extended to protect man against his enemies in the shape of disease germs the future alone can tell. Meanwhile, it is interesting to reflect upon the fact that there is at least a possibility of the abolition of many of the ailments which now affect us by the combined work of attention to the ordinary laws of health and the promotion of a high standard of physical development, and, it may be also, by the work of science in fortifying us by inoculation against the invasion of our disease enemies.

It may be added that the cause and advance of sanitation in England has been encouraged and assisted by various Health Exhibitions held in London and elsewhere, in which the latest sanitary inventions and appliances were shown. One of the fruits of the London Health Exhibition of 1884 was the publication of an admirable series of hand-books, written by eminent sanitarians and physicians, and dealing with the various phases of public and personal health. As regards the advance of sanitary science abroad, Germany has long evinced a thorough appreciation of the advantages of scientific instruction in hygiene, and the Sanitary Institute at Berlin, presided over by Dr Robert Koch, is in its way a model of what such an establishment should be. Laboratories for the study of public health science have been established in connection with most of the English universities; while the Royal College of Physicians of Edinburgh and the Royal College of Surgeons of London have built laboratories specially intended for the study of germ life, and for bacteriological investigations in relation to the production of diseases at large.

In the United States the supervision of health matters is delegated to Boards of Health, of which one exists in each state. These boards receive reports from medical officers and other experts, and publish each an annual report containing much suggestive matter for the guidance of health reformers and for the improvement of the public health at large. Quarantine, conducted on rational principles, with the rigid exclusion of diseases liable to be imported by immigrants, is made a notable feature of the sanitation of the United States.

Hygrometer (Gr. *hygros*, 'moist,' *metron*, 'measure'), an instrument for measuring the quantity of moisture in the atmosphere. The earlier forms of hygrometer depended upon the property possessed by some substances of readily absorbing moisture from the air, and being thereby changed in dimensions or in weight. Of this kind was the hair hygrometer of Saussure, in which a hair, which expands and contracts in length according as the air is more or less moist, was made to move an index; a similar instrument was the whalebone hygrometer of Deluc; but as other causes as well as moisture affect such instruments they afford no accurate indications. The most perfect hygrometer, theoretically, is that of J. E. Daniell (q.v.). It consists of two bulbs connected by a bent tube, as represented in the figure, and enclosing a thermometer, together with some ether

and vapour of ether, the air having been expelled. The bulb *b* is covered with muslin, and *a* is either blackened or coated with metal. The observer's hand is placed for a short time on *b*, to drive the ether into *a*, leaving *b* and the tube filled with vapour of ether. A little ether is then dropped from a flask, of the form *c*, on the muslin-covered bulb; evaporation instantly takes place and produces

a cooling of *b*, which condenses the vapour inside; a fresh evaporation from *a* fills the vacuum, which is again condensed by dropping ether on *b*, and the process is repeated till the temperature of *a* is so reduced by successive evaporations (see EVAPORATION) that *dew* begins to be formed on the outside of the bulb. At the instant this occurs the height of the mercury in the two thermometers is accurately noted, the one giving the dew-point temperature, and the other the temperature of the air. The actual quantity of moisture contained in a cubic foot of air can now be readily found from the following empirical formula: weight of moisture in

grains = $\frac{5656 \cdot 2}{448 \cdot t} \cdot p$; where *t* is the temperature of the air at the time of observation, and *p* (found from tables) the elasticity of vapour at the temperature of the dew-point. The evident defects of this instrument are, first, its rapidity of operation, so that no time is allowed for the glass, ether, and thermometer to come to the same temperature, and in consequence the dew-point is given higher than it actually is; secondly, its costliness, owing to the great consumption of ether; and, thirdly, its uselessness in tropical countries, owing to the difficulty of preserving the ether in a fluid state. Daniell's hygrometer was used at the Royal Observatory, Greenwich, from 1840—the commencement of meteorological observations—till 1847, when it was superseded by the more convenient instrument, the Wet and Dry Bulb Thermometers. This instrument consists of two ordinary thermometers; one has its bulb bare, and this shows the temperature of the air; the other has its bulb covered with

muslin, which is kept wet by a cotton wick dipping into water. The evaporation from the muslin, and consequent cooling of the bulb, being in proportion to the dryness of the air, the difference between the readings of the two thermometers is greatest when the air is driest, and zero when it is completely saturated. The readings of the thermometers being taken, the elastic force of vapour at the dew-point is calculated by the formula of Dr Apjohn:

$$(1) F = f - \frac{d \cdot h}{88 \cdot 30}; \quad (2) F = f - \frac{d \cdot h}{96 \cdot 30};$$

the first formula to be used when the wet thermometer is above, and the second when it is below the freezing-point (32). In these formulae F is the elastic force of vapour at the dew-point, which has been determined for different temperatures by Regnault from carefully conducted experiments; f , the elastic force at the temperature of evaporation (or reading of wet bulb); d , the difference between the dry and wet bulbs; and h , the height of the barometer. From this the quantity of moisture in a cubic foot of air, &c. can be found as before. To dispense with these troublesome calculations the *Hygrometric Tables* of Mr Glaisher may be used, except in very dry states of the atmosphere, such as occasionally occur on Ben Nevis and very dry climates, when Dr Apjohn's formula must be used.

Hygroscope is a name sometimes given to an instrument for indicating the presence of moisture in the atmosphere, without measuring its amount. Hygroscopic substances are those which imbibite moisture and become coated with a moist film.

Hyksos, or SHEPHERD KINGS. See EGYPT, Vol. IV. p. 239.

Hymen, or HYMENEUS, in Greek Mythology, the god of marriage; but originally the word seems to have denoted only the bridal-song, which was sung by the companions of the bride as she went from her father's house to that of the bridegroom. The god Hymen is first mentioned by Sappho. The legends concerning his birth and descent are various; but he is generally said to be a son of Apollo and some one of the Muses. He is represented as a youth with wings, a bigger and graver Cupid, with a bridal torch and a veil in his hands.

Hymenoptera (Gr., 'membrane-winged'), an order of insects, including (*a*) ants, bees, wasps (*Aculeata*)—with stings; and, in a lower division, (*b*) gall-flies, saw-flies, and ichneumon-flies (*Terebrantia*), in which the abdomen of the female bears a boring ovipositor. The mouth parts are adapted both for biting and sucking. The wings are typically four, membranous, and with comparatively few veins; they may be caducous or absent; the second pair is always smaller than the first. The metamorphosis is complete. Both in structure and intelligence the hymenoptera occupy a high place among insects, and indeed among animals. Their characteristics will best be gathered from the study of special types. See ANT, BEE, GALL-FLY, SAW-FLY, WASP, and INSECTS.

Hymettus, a mountain (3368 feet) in Attica, now called Trelo Voumi, situated to the south-east of Athens, was famous among the ancients for its honey and its bluish marble. The honey is still in repute.

Hymn. The usually accepted definition of a Christian hymn is that of St Augustine: 'Do you know what a hymn is? It is singing with the praise of God. If you praise God and do not sing, you utter no hymn. If you sing, and praise not God, you utter no hymn. If you praise anything which does not pertain to the praise of God, though in singing you praise, you utter no hymn.' The hymns of the church which are known to us as existing at the time these words were written

(c. 415) were mainly of the character thus defined. With the spread of Christianity, however, changes took place which gave rise to another and broader meaning to the hymn. The expansion of church life and the development of doctrine and practice required that fuller liberty should be extended to sacred song. The outcome of this expansion of the original idea and form of the hymn has resulted in the accumulation of vast stores of sacred lyrics, a large proportion of which have passed from time to time into public use in divine worship. The languages and dialects represented therein number more than two hundred.

I. New Testament Hymns.—The early history of Christianity is in our Sacred Books; and to them we must go for the first examples of Christian song—the Magnificat, the Benedictus, the Angelic anthem (see DOXOLOGY), and the *Nunc Dimittis*. The fourfold record of our Lord's ministry contains no other songs. In the Acts of the Apostles we read of hymns being sung; but of their structure and contents we have no example. On turning to the epistles of St Paul, St James, and St Peter, we have some indications of the nature of the hymns which were then sung. Fragments of what, to every appearance, were familiar hymns in the early church are found therein, some of which are known as the 'faithful sayings' of Holy Writ. These include 'Awake thou that sleepest,' &c., Eph. v. 14; 'If we die with Him, we shall also live with Him,' &c., 2 Tim. ii. 11, 12; 'Manifest in the flesh, justified in the spirit,' &c., 1 Tim. iii. 16; and others, as 1 Tim. vi. 15, 16, Titus, iii. 4, 7, and James, i. 17. The songs which St John heard in vision, although true lyrics, cannot be classed as early Christian hymns.

H. Greek.—(1) In Greek, the mother tongue of Christianity, it is natural for us, when we have closed the Sacred Record, to search for the earliest forms of sacred song. In the Ante-Nicene period we have a few only, some of which are written in the classical metres, and others which are 'more oriental in character, and have an affinity to the Hebrew modes.'

Of the former the best-known instance is that of Clement of Alexandria (died 220?), translated by Dr Dexter as 'Shepherd of tender youth.' Although Clement's authorship is not beyond doubt, yet it is essentially a hymn of his day, and is absolutely confined, in its subject-matter, to the incidents and doctrines of Holy Writ. The hymns and poems of Gregory of Nazianzus (330-389) are all in classical measures. They were probably written after 381, and number about 240 in all, of which 38 are dogmatic, 43 are on moral subjects, 99 relate to his own life, and 60 more are on miscellaneous subjects. Although amongst these sacred pieces there are several splendid hymns, we know not one in a modern hymn-book. Some of the finest are easily attainable in the original in Christ and Parakkas's *Anthologia Græca Cœciliæ Christianorum* (1871), and in a translated form in A. W. Chatfield's *Songs and Hymns of the earliest Greek Christian Poets* (1876). Another writer in the classical metres was Synesius (375-450). He was an eloquent bishop, and well read in the philosophy of his own and of older days. His ten hymns are also printed in the *Anthologia Græca*, and translated by Mr Chatfield and by Alan Stevenson (1865). One of these hymns, translated by Mr Chatfield as 'Lord Jesu, think on me,' is given in a few modern hymnals. 'Though of great spirit, reality, and beauty,' the hymns of Synesius be confessedly on the borderland of Christianity and Neoplatonism, and often it is the Platonic rather than the specially Christian thought that inspires his most refined passages' (*Dict. of Hymnology*, p. 457). The hymns of Sophronius, patriarch of Jerusalem (620), are of a still later date, as are also those of Elias Synellus and St John of Damascus. Of these hymns in the classical measures none, except three canons of St John of Damascus, were incorporated in the services of the Eastern Church.

(2) The link of connection between the Jewish

and the Christian hymnody is found not only in the use which was made from the very first of the Jewish Psalter in Christian worship, but also in the adoption of the ancient 'Hallelujah' and 'Hosanna,' and in the alphabetical and other forms of Christian antiphons and versicles. The primitive Greek hymns, as distinct from hymns of the New Testament on the one hand, and the sacred poems in classical metres on the other, were largely derived from Holy Scripture.

The *Te Sanctus* is an expansion of Isaiah, vi. 3, and usually reads 'Holy, holy, holy, Lord of Sabaoth; Heaven and earth are full of His glory. Blessed art Thou for ever. Amen.' The germ of the *Gloria in Excelsis* is the Anglican song at Bethlehem. The Greek form of the *Gloria Patri* ('Glory be to the Father,' &c.) seems to have had its origin in Our Lord's commission, 'Go ye therefore . . . baptising them in the name of the Father, and of the Son, and of the Holy Ghost.' Besides these, the *Trisagion*, 'Holy God, Holy and Mighty. Holy and Immortal, have mercy upon us;' the *Cherubic Hymn* of the Greek liturgies, 'Let us who mystically represent the Cherubim, and sing the holy hymn to the quickening Trinity, lay by at this time all worldly cares, that we may receive the King of Glory, invisibly attended by the angelic orders, Alleluia, Alleluia, Alleluia;' the hymn of Justinian, 'Only-begotten Son and Word of God,' &c.; and various clauses in the *Te Deum* are all based upon separate or accumulated passages of Holy Scripture.

There are also the hymn at lamp-lighting, widely known through Keble's translation, 'Hail! gladdening Light,' which was old in St Basil's time (370); 'The Virgin's Song' of Methodius (died c. 311), translated by Mr Chatfield as 'The Bridgroom cometh!' but not in liturgical use in ancient or modern times; and a few others. Early Greek hymns are few in number but of fine quality, and deal almost exclusively with scriptural subjects.

(3) The liturgical use of hymns in the church's infancy does not seem to have been extensive. Both Pliny and Justin Martyr bear testimony to their use in public worship, and we know that some were in use in the church of Antioch in 260. 'Yet as late as the 4th and 5th centuries there was a scruple against the use of anything but psalms in the eastern monasteries, and in Spain the Council of Braga (561) forbade the use of hymns' (*Dict. of Hymnol.* p. 460). Ultimately, however, the popularity and power of hymns became so marked through their use by the heretics, and their employment as a counter-check by the faithful, that their exclusion from divine worship became no longer possible. The change was on a limited scale at first, but after the complete separation of the Eastern from the Western Church the hymn in its various forms gradually assumed a prominent and permanent position in the Greek liturgy.

(4) It has been pointed out that the principal link between the early and later hymns is found in a group of pieces discovered by Cardinal Pitra in two rare liturgical MSS. at Moscow and Rome (Cardinal Pitra's *Amalthea Sacra Inedita*, Paris, 1876).

(5) The next period (600-900) is that in which we have the building up of those elaborate service-books of the Greek Church, known to us as the *Menaia*, the *Genaria Octoechus*, the *Lesser Octoechus*, the *Triodion*, the *Pentecostarian*, the *Exocholouan*, and the *Hodegion*. In these works the number and variety of hymns are very numerous. The hymn-writers of this period were associated at first with Jerusalem and other parts of the Holy Land, and subsequently with Constantinople.

(a) The *first group* includes St Andrew, Archbishop of Crete (600-c. 732), who is known as the author of several canons, triodia, and idiomela, including the great canon of the Mid Lent week. To the English reader he is best known through the cento, made by Dr Neale, 'Christian, dost thou see them?' Almost

contemporary with him was St Cosmas, a monk of St Sabas, near Jerusalem, and afterwards Bishop of Maiuma, near Gaza, who died c. 760. He was the author of several pieces, including a canon for Christmas Day, beginning in Dr Neale's translation, 'Christ is born! tell forth His fame.' At St Sabas with Cosmas was John of Damascus, who became a tower of strength in Greek hymnody. Born at Damascus, he accompanied his foster-brother, Cosmas, to St Sabas, and there he wrote his theological works and his hymns. Late in life he entered the priesthood, and died at a great age (c. 780). His influence upon later Greek hymnody was very great. He arranged the *Octoechus* in accordance with the Eight Tones, and supplied it with several canons of great merit. His canons are his finest work, that for Easter (beginning in Dr Neale's translation, 'Tis the day of Resurrection') being well known, in part at least, to the English reader. Within the next fifty years St Theophanes, a native of Jerusalem, also of St Sabas, and afterwards Archbishop of Mida, was writing extensively on the martyrs and confessors of the Greek Calendar, which took the form of canons and idiomela. Although largely represented in the *Menaia*, he is almost unknown to the English reader.

(b) The *second group* of hymn-writers were associated with Constantinople. The first of these is Joseph the Hymnographer (died 833), a native of Sicily, but afterwards founder of a monastery at Constantinople. He was one of the most voluminous of the Greek poets, and is largely represented amongst the canons in the *Menaia*. His canon for Ascension Day is very fine. Of it, however, but a small portion is familiar to English readers. Ode iv., translated by Dr Neale as 'Jesus, Lord of life eternal,' being the best known. 'Let our choir now anthems raise,' and 'Stars of the morning so gloriously bright,' are also translations by Dr Neale from St Joseph. St Joseph of the Studium, sometime Bishop of Thessalonica, wrote several pieces; but none of them have been translated into English. His elder brother, St Theodore of the Studium (died 826), wrote several canons, notably that on the Judgment, translated by Dr Neale as 'That fearful day, that day of speechless dread,' and regarded by Neale as 'undoubtedly the grandest judgment-hymn of the church previous to the *Dos Ica*.' He also wrote 'A song, a song of gladness,' which is a part of his triumphal canon on the victory of the Icons. Methodius II. (died 836) also belongs to this group of poets. Of the few pieces which he wrote, Dr Neale has translated one only, 'Are thy toils and woes increasing?' and has given it as by St Methodius I. in error. Theoctistus of the Studium (c. 890), said by Dr Neale to have been a friend of St Joseph's, is not largely represented in Greek hymnody. He is known to English readers through Dr Neale's translation of a cento from his 'Suppliant Canon to Jesus,' as 'Jesus, Name all Names above,' and the Rev. R. M. Moorson's rendering of the same, 'Sweet Saviour, in Thy pitying grace.'

(6) From this date to the 16th century, when the Greek service-books were practically closed against new compositions, very few names are known. We have Metrophanes (died 910); Euthymius (died 910); Constantine Porphyrogenitus (913-959); Leo VI. (died 917); John Mauropus (died 1060); and Philotheus, Patriarch of Constantinople (died 1376); but only one or two pieces by these writers have been rendered into English.

III. *Syriac* (170-1370).—Syriac hymnody deals with the churches of Syria, Upper Mesopotamia, and western Persia. Its history extends from the 2d to the 14th century.

The earliest known hymn-writer in this language is Bar-Daisan (Bardesanes, q.v.), born in 151. His son Harmonius was also a hymn-writer. Both father and son had Gnostic tendencies. On the orthodox side we have Simeon bar Sabbae, Bishop of Seleucia, who suffered martyrdom in 296; and the greatest of all, Ephraem Syrus (q.v.; c. 306-378). His poetical writings were numerous, and included homilies, discourses on Christ's Nativity, the Creation, and other subjects. Most of the Syriac hymns and hymnists are practically unknown to the western world. In the East, however, these hymns form a considerable portion of the service-books of the various divisions of the Syriac churches to the present

day. Their English use is very limited. The best-known example is 'Glad sight, the holy Church,' by the Rev. F. Pott.

IV. *Latin*.—(1) No name is associated with Latin hymns until after the Council of Nicea, 325. Almost immediately afterwards we have three great contemporary writers: in Greek, Gregory of Nazianzus (330-389); in Syriac, Ephraem Syrus (306-378); and in Latin, St Hilary (died 368). The most celebrated of the hymns attributed to the last is the 'Beata nobis gaudia Anni reduxit orbita,' which has been in western liturgies from an early date. St Ambrose (c. 340-397) was almost a contemporary writer with the above three. About 100 hymns are attributed to him, but of these only twelve are accepted by the Benedictine editors of his works, including 'Eterna Christi munera,' 'Deus Creator omnium,' 'O Lux beata Trinitas,' and 'Splendor Paternae gloriæ.' The rest, being in his style and after his manner, are known as Ambrosian hymns. Most of the latter and all of those by St Ambrose are found in the early liturgies of the Western Church. Prudentius (350-410) did not write hymns, but sacred poems, from which portions were taken and incorporated as hymns in the services of the church. For this purpose these extracts were admirably suited and widely used. His 'Corde natus ex Parentis,' which was taken from his poem 'Da, puer, plectrum,' in his *Cathemerinon*, is a good example of this mode of treatment. The 63d edition of Prudentius' *Poems* was published at Leipzig in 1809. This is a splendid testimony to his worth. Sedulius, a contemporary of Prudentius, is known in hymnology by one piece, 'A solis ortus cardine, Ad usque,' of which the second portion, 'Hostis Herodes impio,' is used as an Epiphany hymn in several early breviaries, and altered, as 'Crucelis Herodes Deum,' in the modern Roman Breviary. The 6th century embraces two names of great repute: Venantius Fortunatus (530-609), and Gregory the Great (540-604). Fortunatus' *Poems* are extant in eleven books. Some ten or twelve hymns bear his name, but his right to several of these is contested. His grandest productions are the Passiontide hymns, 'Vexilla Regis prodeunt' and 'Pange lingua gloriosi prælium certaminis.' Gregory's accredited hymns are about a dozen, including 'Audi benigne conditor,' 'Ecce jam noctis,' 'Rex Christe factor omnium,' and 'Summi largitor premii.' The fairly well authenticated hymns of the Venerable Bede (673-735) number ten or twelve only at the utmost, including his 'Hymnum eunamus Domino,' and 'Hymnum canentes martyrum.' Another hundred years give us Paul the Deacon (died c. 799) and St Theodolph of Orleans (died 821), the 'Gloria laus et honor' of the latter being long and well known as a processional hymn for Palm Sunday. St Rabanus (776-856), with his 'Christe Sanctorem decens Angelorum,' and St Odo of Cluny (879-912), with his 'Lauda mater ecclesia,' should be mentioned, as also Fulbert of Chartres (died 1028), author of the 'Chorus novæ Hierusalem,' and Robert H., king of France (972-1031), though their claims to hymn writing are open to question.

(2) Although this brings us to the beginning of the 11th century, the hymn-writers whom we have been enabled to cite are comparatively few. Most of them, however, are names of great standing, and are towers of hymnological strength. When, however, all the compositions of these writers are collected together we still find in the ancient Latin service books and other MSS. a mass of hymnological literature for which no authorship can be found. This is also the case with regard to the succeeding centuries, and more especially with respect to the Prose or Sequence.

(3) Notker Balbulus (c. 810-912), the father of sequence-writing, was a member of the Benedictine monastery of St Gall, his principal work being literary and scholastic. In connection with divine worship he found it difficult to remember the musical notes (*neumes*) set to the 'Alleluia' especially to the final *o*, which were sung between the reading of the Epistle and the Gospel. The adapting of words to these *neumes*, instead of sounding them as musical notes only, was suggested to him by another, and the result was a series of Sequences, or, as we now call them, hymns, which to the number of 115 are known as Notkerian Sequences, but of which less than fifty are by Notker. Of those who followed Notker in this mode of composition Adam of St Victor (an abbey at Paris) was the most prominent. The service-books of the middle ages abound with these compositions, but the greater proportion by far are anonymous. The Notkerian Sequence which is best known to the English reader is that for the Epiphany, translated by Dr Neale as 'The strain upraise of joy and praise, Alleluia.'

(4) Whilst the work of composing hymns and sequences was thus prolific, a few names of great note stand forth in their grandeur as composers of sacred poems as distinct from hymns. It will be sufficient to name St Bernard of Clairvaux (1091-1153), and his grand Passiontide poem 'Salve mundi salutare,' and his contemporary, Bernard of Châny, with his splendid 'Hora novissima,' to show the nature and character of the work which was done. See DRES B.R.E.

(5) The hymns, sequences, and poems referred to above, to the number of several thousands, are those which date from before the 16th century. Some hundreds more were added to the stores of Latin hymnody by the brothers Santeuil and others in the Clunian (1686), the Paris (1736), and other breviaries in France, additions to the latter being as late as 1820. As to the use made of this mass of sacred poetry, we may add that two-thirds or more have been associated directly with divine worship, and the rest are connected with works of private devotion; and that nearly one-fourth have been translated into English.

V. *English*.—English hymnody is a very wide subject, and, if we include therein Anglo-Saxon compositions, it dates from Caedmon (died c. 680). Bishop Aldhelm (died 709) sang sacred poems in the vernacular, and is said to have rendered the Psalter into metre; in Chaucer (1340-1400) we have an early English hymn to the Blessed Virgin; in 1441 T. Brampton's Seven Penitential Psalms, and later carols and additional hymns to the Blessed Virgin Mary. The first instalment of hymns in the vernacular of any moment were those translated from the Latin, and included in the Primers which were issued both before and after the Reformation. These translations were followed by others, some of which are preserved to us in the Book of Common Prayer. Translating, however, soon gave way to paraphrasing, and Latin and German hymns to the Book of Psalms. The supplying of the need occasioned by the suppression of Latin hymns in divine worship at the Reformation, by the introduction of the Paraphrase instead of the hymn, is a history in itself. We can only say that from 1561 to 1696 the authorised book in the Church of England was the 'Old Version' of Sternhold and Hopkins, and from the latter date to the adoption of modern hymn-books, the 'New Version' of Tate and Brady. In the meantime the foundations of English hymnody were being extended. A *resumé* of the work done in the Elizabethan age is given in E. Farr's *Sacred Poetry, chiefly devotional, of the Reign of Elizabeth* (Parker Soc., 1815). The speci-

mens given are either from books of poetry or works of devotion, and are pious utterances in quaint and rugged verse. Later attempts in the same direction, by Dr Donne in his *Poems* (1633), G. Herbert in his *Temple* (1633), C. Harvey in his *Synagogue* (1640), and others, were of a higher stamp, and bore a greater affinity to the modern hymn. At that time no use of these compositions was made in public worship, except in the case of private institutions. The hymn 'Jerusalem, my happy home,' and others of more than usual excellence are of this period.

The first English hymn-book was the *Hymns and Songs of the Church* (1623), by George Wither. The king granted him a patent to bind up the book with the Metrical Psalms; but the whole matter resulted in a failure. In 1641 Wither republished the same, with a few alterations, as *Hallelujah, Britain's Second Remembrance*, and dedicated it to the Long Parliament, but with no better success. The writings of Herrick, Henry Vaughan, William Barton, Bishop Jeremy Taylor, Samuel Crossman, Richard Crashaw, John Austin, Bishop Thomas Ken, and others bring us down to 1737, when the first hymn-book of the modern type (in which the original hymns of various authors are interspersed with translations from other languages) was published by John Wesley for use in the Church of England.

(1) *Church of England*.—The title of Wesley's book was *Collection of Psalms and Hymns* (Charlestown: printed by Lewis Timothy, 1737). The versions of psalms, the translations from Greek and German, and the original compositions were seventy in all. Wesley and his brother Charles soon changed the style of their hymnological productions, and from 1740 to 1780 (the date of the Wesleyan hymn-book) published only their own compositions. John Wesley's hymnological work for the Church of England remained a dead-letter until 1760, when Martin Madan published his *Collection of Psalms and Hymns*, gathered by him mainly from the Wesleys and Isaac Watts, altered without permission to suit his Calvinistic views, and published without leave.

During 1760-1800 nearly twenty distinct hymn-books were issued. Taken as a whole they were Calvinistic in doctrine, crude in arrangement, and indebted to the Wesleys and Nonconformists for seven-eighths of their contents. Three writers only stand out during this period with marked distinctness: A. M. Toplady, John Newton, and William Cowper. During the next twenty years nearly one hundred hymn-books were issued for use in the Church of England, and the places of publication extended to almost every county in the country. Naturally these books varied in their contents; but their general doctrinal tone was distinctly Calvinistic. There was also a greater and more uniform recognition of the order of the Book of Common Prayer than before. The years 1820-50 produced another hundred of hymn-books, amongst them Beckerist's *Christian Psalms* (1833-4), Elliott's *Psalms and Hymns* (1835), and Hall's *Metric Hymn-book* (1836). Other works of importance were Bishop Heber's posthumous *Hymns* (1827), Miss Anker's *Spirit of the Psalms* (1829), Bathurst's *Psalms and Hymns* (1831), and Lyte's *Spirit of the Psalms* (1834), the contents of which, in each instance, were mainly by the same writer. During this period also this score was richly increased by the publication of Koble's *Christian Year*, by the original compositions of several other writers, and by renewed efforts at translation of German and Latin hymns. This immense growth broadened out considerably, and brought the subject of hymnody strongly to the front during the next ten years. The outcome was the publication of over fifty hymn-books in that period, a great accumulation of original hymns and translations, the gradual exclusion of nonconformist hymns, except those of the higher class, from the collections, and a new and intense interest in the whole subject. Additional translations from the Latin and German, together with original com-

positions of great merit, created a longing for something better in the form of a hymn-book for public use. *Hymns Ancient and Modern* (1861) was one answer to this request. Its success was phenomenal. On the one hand it raised a storm of opposition; on the other, during the next twenty-five years it called forth several important works on hymnology, various collections of sacred lyrics for private use, about fifty 'supplements' to and editions of books in common use, and nearly one hundred new hymn-books. Since then new writers whose names have become household words have arisen, and the needs of the increased activity of the church have been met. In the past one hundred and fifty years the Church of England has produced about five hundred hymn-books, and nearly two hundred and fifty authors and translators whose works have been at one time or another in use in public worship. Taken together their original hymns and translations will number ten thousand.

(2) *English Nonconformists*.—The hymnological work which has been accomplished outside of the Church of England is large and important, and has had great influence in all English-speaking countries. A few facts only can be set forth in each instance.

(a) *The Baptists* from the first quarter of the 17th century to the present have been divided into two sections, the Particular or Calvinistic, and the General or Arminian Baptists. The singing of hymns with the former began with B. Keach, about 1673. It had a stormy birth and childhood, for opposition thereto was great, but at the present time hymn singing is a distinctive feature in their worship. The General Baptists also have their official hymn-books, and singing is an essential part of their worship. English Baptist writers number about one hundred, and their hymns two thousand.

(b) *The Congregationalists or Independents* used hymns in public worship some thirty years before the Baptists. Their hymn-books have been many, and their writers numerous. The latter number over a hundred, and their hymns three thousand or more. Although I. Watts, P. Doddridge, and J. Corder are their pride and towers of strength, there are others who have written lyrics of great force and beauty.

(c) *The Methodists* are broken up into several sections, as the New Connection (1796), Primitive Methodists (1810), the United Methodist Free Churches (an amalgamated body dating from 1857), and the Bible Christians (1815). The first official hymn-book of the old body was published by J. Wesley in 1780, and is the groundwork of all the hymn-books of the various branches of Methodism—the Primitive Methodists alone excepted. Usually Methodist hymnody is said to have had a great influence upon English hymnody everywhere. This, however, is only true of the hymns of John and Charles Wesley.

(d) *The Unitarians*, although numerically a weak body, have produced several hymn-writers of great merit. Of their present hymn-books the best is Dr Martineau's *Hymns of Peace and Praise* (1873), which is unequalled amongst Unitarians.

(e) *Other Denominations*, as the Irvingites, the Swedenborgians, the Salvation Army, and many others have each their authors and official hymn-books. The writers and books, however, do not call for special notice.

When the English hymn writers are counted up and their works are tabulated, we have a total of 1000 writers, and 25,000 hymns.

VI. *Irish*.—The Roman Catholics, the Protestant Episcopalians, the Presbyterians, the Methodists, and others in Ireland have been so closely identified with their brethren in England and Scotland that in most instances the same books have been in use in the three countries. The result has been that Ireland has not shaped a hymnody for herself, although in later years a few hymn-books have been published independently. The Irish Church has, however, an authorised hymnal, *The Church Hymnal* 1873, with supplement of later date. In this respect it is greatly in advance of the Church of England.

VII. *Welsh*.—There are references in Welsh history which go to show that some of her ancient bards sang hymns of praise to God as early as the 6th century. The most ancient productions now extant date from the 14th century. After the Reformation the lead was taken by the Established Church, by the publication of Archdeacon Prys's version of the Psalms in 1621. Since then hymn-writing has increased somewhat rapidly, especially since the Methodist movement early in the last century; and at the present time the Established Church and the numerous Nonconformist bodies have each their official or quasi-official hymn-books. Welsh hymnody, although very powerful in the principality, has had little or no influence upon the hymnody of other countries.

VIII. *Scottish*.—One of the most interesting parts of Scottish hymnody is the history of the Scottish Psalter, a work which is interwoven with Scottish history, and has had a powerful influence upon the Scottish mind. The first effectual step taken to provide hymns, as distinct from psalm versions, for public worship in Scotland, was the appointment of a committee of the General Assembly in 1742. This committee presented a draft collection, which was authorised for private use in 1745. The same year a committee was appointed to revise and enlarge the draft for public use. The result was published in 1751 as *Translations and Paraphrases, in Verse, of several Passages of Sacred Scripture, &c.* Of the total contents (sixty-seven in all, not counting the five hymns added at the end) twenty-five are by Watts, five by Doddridge, and two by Tate, the rest being by M. Bruce, T. Blacklock, H. Blair, W. Cameron, J. Logan, J. Morison, and other Scottish writers.

Although the addition of the five hymns to the Paraphrases indicated a desire for a larger choice of hymns in public worship, nothing definite and official was done by the principal sections of Presbyterianism until the publication of the *Hymn-book of the Relief Church* (1794), the *Hymn-book of the United Presbyterian Church* (1852), the *Scottish Hymnal* of the Established Church (1870), and the *Psalms-versions, Paraphrases, and Hymns of the Free Church* (1873). These have been revised, added to, or superseded—notably by the *Hymnary* for the Established, Free, and F.P. Churches in Scotland, and the Irish Presbyterian Church (1898). Much activity has been shown by individuals amongst Presbyterians, Scottish Episcopalians, Evangelical Unionists, Baptists, Congregationalists, Glasites or Sandemanians, Roman Catholics, and others, the outcome of which is a mass of hymnological literature, of which a good proportion is of Scottish origin and of high merit. Amongst the ninety to one hundred Scottish authors and translators whose hymns have taken a high place in the hymnody of the church the most eminent are J. Morison, R. Blair, S. Martin, W. Robertson, H. Bonar, Jane Borthwick, M. Bruce, J. D. Burns, Sarah Findlater, R. M. McCheyne, H. M. Macgill, and R. Wardlaw. The prince of these hymn-writers and the Charles Wesley of Scotland is Dr Horatius Bonar (1808-89).

IX. *American*.—The first book printed in America was the Bay Psalter (1640), consisting of various metrical versions of the Psalms by English authors. The addition of a few spiritual songs in the 2d edition of 1647 was the first departure from the sole use of psalm-versions in that country. This small beginning had at the first a very slow development. The years 1780-1800 witnessed the general recognition of hymns. The Protestant Episcopal Church extended their collection in 1789 to twenty-seven hymns; a collection by the Baptists (the second) was published in 1790;

the Congregationalists had their *Hartford Selection* in 1799; the Wesleyan Methodists a reprint of a *Pocket Hymn-book* originally published at York, and revised after some years of use in 1802; the Universalists, two collections in 1792; the Unitarians, a selection in 1795; and the Presbyterians, Watts at first, and then an official collection in 1828. In these books American hymn-writers had a very limited representation, most of the hymns being by English authors; but year by year the American element became more pronounced as hymnals followed hymnals in the various religious communions. In 1800 an original hymn by an American was a novelty in any collection; now no American hymn-book of the highest class can do with less than two hundred and fifty authors and translators, and of these not less than fifty should be Americans. This percentage, as the outgrowth of some eighty years, is remarkable. Each religious communion has done its part in bringing about this great result. Of the two hundred and fifty authors and translators, the Baptists and the Unitarians number over forty-five each, the Congregationalists about forty; the Protestant Episcopalians and the Presbyterians about thirty each, the Methodists less than twenty, and the Universalists about ten. The remaining thirty include Quakers, Reformed Germans, Reformed Dutch, &c. Several of these writers have an European reputation, as Bishop Coxé, Bishop Doane, C. W. Everest, and W. A. Muhlenberg (Episcopalians); T. Hastings and J. W. Alexander (Presbyterians); H. M. Dexter, T. Dwight, and Ray Palmer (Congregationalists); P. Bliss, Lydia Sigourney, and S. F. Smith (Baptists); Fanny Van Alstyne and W. Hunter (Methodists); S. G. Ballinch, W. C. Bryant, W. H. Burleigh, Emerson, Holmes, Longfellow, S. Longfellow, Lowell, and E. H. Sears (Unitarians); and the Quaker poet Whittier.

The number of hymn-books published in America during the past hundred years accounts to a great extent for this great activity in hymn-writing. At the present time each denomination, and there are many, has its official hymn-book, or its quasi-official book or books. For good work opportunities for publication thus abound, and the finer productions are assured a certain circulation and a possible immortality.

X. *French*.—The French metrical psalters have a history distinct from French hymns and hymn-books. The complete psalter of Marot and Beza (1552-62) was the psalm-book of the Reformed Church until its place was to some extent filled by the new version of Comart (1677-79), and the revision of the same by Pietet and others in 1695. As in other countries, the psalter subsequently gave way to the hymnal, and the versions of private individuals were mainly of public value in proportion as they yielded suitable pieces for the same. The writing of hymns in the vernacular began in the 16th century as in Germany and elsewhere with translations from the Latin. The Roman Catholics, the Huguenots (in their day), the Reformed Church, the French Moravians, the Methodists, and various evangelical societies, have each their book or books of hymns for divine worship, in which, although there are original compositions by French authors, the larger proportion are translations from English and German hymns. *The Brevel* has produced the greatest French Protestant hymn-writers, at the head of whom stands César Malan (1787-1864), whose printed and MS. hymns number about one thousand. Associated with him, directly or indirectly, in the same religious movement were Ami Bost, H. Empaytaz, Abelé d'Aubigné, Felix Neff, Henri Lutteroth, A. Vinet, A. Monod, and others, men of

world-wide reputation and influence, who have given a position to French hymnody unknown to it before.

XI. *German*.—In the German language there are not less than one hundred thousand hymns, of which about ten thousand have passed into German hymn-books of various dates, and nearly a thousand are regarded by German critics as classical. The first were contemporary with the earliest Latin sequences of St. Notker and others; the last are the productions of living men.

(1) *The First Period* begins with Otrid of Weissenburg (c. 868), and was continued by others until the time of Luther. The greater part of the hymns of this period were translations from the Latin, and all were in strict doctrinal accord with the Church of Rome.

(2) *The Second Period* (1520-1648) opens with the hymns and psalm-versions by Luther, and embraces the Reformation period to the peace of Westphalia. The principal writers were Luther, Justus Jonas, Alber, Spengler, Hans Sachs, Speratus, N. Decus, and others. The writings of these authors reached to about 1570, and have a distinct churchly character of their own. From 1577 to 1618 hymn-writing and hymn-book making continued very much on the old lines, and numbered amongst the writers Selmecker, Ringwaldt, Herberger, and P. Nicolai. The miseries of the Thirty Years' War changed the whole aspect of hymn-writing for a time; by the introduction of a strong personal element of faith and courage, and hope begotten of suffering. The names of a few of these writers will recall some of the finest hymns of this kind in the German language: Opitz, Heermann, M. A. von Lowenstern, Altenburg, Runkart, Bach, and Rist.

(3) *The Third Period* was a transitional one, and led up to the Pietistic and Moravian writers of the next era. It had amongst its hymn-writers P. Gerhardt, Franck, Neumark, Scheffler, and Louise Henriette of Brandenburg. Of these the greatest was Gerhardt, who is second only to Luther in German hymnody, and Scheffler, whose love for Christ was first in everything. This orthodox, mystic school, with its deep experimental piety, was soon lost in the Pietism of the next period.

(4) *The Fourth Period*, commonly known as the Pietistic and Moravian era, 'was a reaction against the dry scholasticism and cold formalism of the Lutheran Church,' and an emphatic pronouncement in favour of 'practical, personal, and experimental piety.' On the Lutheran side the leading writers were Speier, Francke, Richter, Freylinghausen, G. Arnold, J. Lange, Dessler, Rambach, Bogatzky, Schmolek, and Hiller; and on the Moravian, Count Zinzendorf. These names recall numerous hymns of deep spirituality, high refinement, and great power.

During this same period the German Reformed Church broke away from its long-continued and almost exclusive use of the Psalms in metrical form. Their first hymn-book appeared at Zurich in 1540. This was followed by A. Lobwasser's rhymed translation of the French Psalter of Marot and Beza in 1573. Another hundred and fifty years brought them into closer hymnological conformity with their Lutheran brethren, and produced amongst others three well-known hymn-writers, J. Neander, Lampe, and Tersteegen.

(5) *The Fifth Period* embraced about sixty years (1757-1817), and covers the time when the great wave of Rationalism broke in upon the German churches, and for a time changed the whole aspect of their hymnody. Old hymns were altered or entirely rewritten, and new hymns written partaking of the nature of rhymed sermons on the existence of God, the immortality of the soul, the dignity of man, the obligations of moral duties, and kindred subjects. To the hymn-writers of this order there were a few notable exceptions, which included Gellert, Klopstock, J. C. Lavater, and M. Claudius, the greatest being Gellert and Klopstock.

(6) *The Sixth Period* is rich in writers. Beginning almost with the 19th century, it extends to the present time, and embraces the well-known names of F. von Hardenberg ('Novalis'), E. M. Arndt, F. A. Krummacker, F. W. Krummacker, A. Knapp, J. P. Lange, Spitta, and Gerok.

This digest of the hymnological work of more than a thousand years in one language can give

only the slightest idea of what was done. Little or nothing has been said about the multitude of hymn-books (*Gesangbuecher*) which were issued and brought into common use in the church and in the home, nor of the metrical versions of the Psalms, which have a history of their own. We can do no more than recall and emphasise the facts, and refer to special treatises for details. The influence of German hymns upon English and American hymnody has been very great. In fact, until the modern revival of translating hymns from the Latin and other languages, German was almost the only source from whence hymns other than English were taken for use in the hymn books of Great Britain and America; and at the present time, especially in America, it holds a prominent position in the hymnals of almost every party and creed. For the Dutch, Italian, Bohemian, Moravian, and Scandinavian hymns, and those in use in foreign missions (in more than 150 languages and dialects), see the present writer's *Dictionary of Hymnology* (1892).

Conclusion.—From the outset of the propagation of Christianity throughout the nations of the earth it became a necessity to preach to the people in their own languages, and gradually to supply them with hymns in their own tongues. This has resulted, as we have seen, not only in a great number of languages being represented in Christian hymnody, but also in a vast variety of metrical forms being found therein. Some of these forms are intimately associated with the ancient classical measures, whilst others are widely divergent therefrom, and seem to have had little or no laws of control beyond the fashion of the period or the fancy of the writers. With this broadening out of languages and forms came also a rapid increase in the number of subjects which engaged the attention of Christian poets. At an early stage of church history reverent strophes in praise of the Holy Trinity, and especially in adoration and praise of the Eternal Son, together with a metrical homily or two and a few impassioned songs on the practical side of Christian life, formed the staple of sacred song. We have seen how the expansion of church life and the development of doctrine and practices called forth a fuller and more extended hymnody, until every incident of importance in Bible story, every conceivable shade of Christian doctrine and ritual, every epoch in the church's history, every experience in her children's life, from the sufferings of her little ones to the magnificent self-sacrifices of her martyrs, have been enshrined in sacred song.

Hyōgō, or **KOBE**, a port of central Japan, situated on the west shore of the Gulf of Osaka, about 20 miles S. of that city. Hyogo is properly on the west side, and Kobe on the east of an unimportant river. Open to foreign trade since 1868, it is connected by railway with Osaka, and has a large direct foreign trade with Europe, America, and Australia. The place has foreign banks, wharves for ocean steamers, extensive shipbuilding yards, and a large paper mill. Pop. (1895) 153,382. The imports have an annual value of about £5,000,000; the exports (rice, tea, silk, camphor, fish, matches, porcelain, umbrellas) of about £1,000,000.

Hyoid Bone, in human anatomy, is a bony arch consisting of five movable parts, quite separate from the rest of the skeleton, and lying in the fleshy parts of the neck between the root of the tongue and the larynx (see TONGUE). For the hyoid bone of the dog, see the figure at Dog.

Hyoseyanus. See HUSBANE.

Hypatia, daughter and pupil of Theon, an astronomer and mathematician of Alexandria, was born in the later part of the 4th century A.D. Her

learning and wisdom made her the most influential teacher in Alexandria, and the fame of her lectures drew round her students from all parts of the East where the influence of Greek thought and knowledge was felt. The philosophy she taught seems to have been an eclecticism, the results of an endeavour to combine Neoplatonism with Aristotelianism; but her thoughts were principally given to astronomy and mechanics. Personally she was held in such great esteem, and such reliance was placed on her judgment and sagacity, that the magistrates used frequently to consult her on important cases. At this time the Bishop of Alexandria was Cyril (q.v.), a fierce hater of heathens and heretics. With his connivance, if not at his instigation, certain savage monks from the Nitrian deserts, headed by one Peter, a reader, attacked Hypatia in the streets as she was returning from her lecture-room, dragged her from her chariot, hurried her to the Cæsareum (then a church), there stripped her naked, and hacked her to death with oyster shells, after which she was torn to pieces, and her limbs carried to a place called Cinanon, and there burned to ashes (415). None of her writings have survived. Kingsley's romance, *Hypatia*, appeared in 1853.

Hyperæsthesia (Gr. *hyper*, 'over,' *aisthēsis*, 'a sensation'), in the most general sense of the word, denotes an excessive excitability of the parts of the nervous apparatus which have to do with sensation, special or common. Abnormal sensibility to pain is, however, more correctly called *hyperalgesia*. In this condition, as in Tic-douloureux (q.v.), the slightest stimulus may cause a paroxysm of pain, even a current of air or a noise bringing on an attack; while in hyperæsthesia of the special senses bright flashes of light may be seen, sounds may be heard, and even smells and tastes experienced in the absence of any objective cause. Of the diseases predisposing to hyperæsthesia hysteria is far the most frequent; but it is sometimes induced by rheumatism, gout, skin diseases, inflammatory affections of the central nervous system, while it often adds greatly to the distress in the early stages of various fevers. The treatment of hyperæsthesia is that of the morbid change on which it depends, but the local application of anodynes, ice, or warm poultices, and sometimes the use of electricity may do much to diminish the patient's sufferings for the time.

Hyperbola. If two similar cones be placed apex to apex, and with the lines joining the apex and centre of base in each, in a straight line; then if a plane which does not pass through the apex be made to cut both cones, each of the two sections will be a *hyperbola*, as PBN, P'AN'.

It is, viewed analytically, the locus of the point to which the straight lines EP, FP differing by a constant quantity are drawn from two given points, E and F. These given points are called the *foci*, one being situated in each hyperbola. The point G, midway between the two foci, is called the *centre*, and the line EF the *transverse axis* of the

hyperbola. A line through G perpendicular to the transverse axis is called the *conjugate axis*; and a circle described from centre B, with a radius equal to EG, will cut the conjugate axis in C and D. If G be taken for the origin of co-ordinates, and EM and E'P' for the axes, the hyperbola is expressed by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$. (GB = a, GC = b). The

hyperbola is the only conic section which has Asymptotes (q.v.); in the figure these are GT, GT', GS, GS'. It also appears that, if the axes of co-ordinates be turned at right angles to their former position, two additional curves, HCK, H'DK', will be formed, whose equation is $\frac{x'^2}{b^2} - \frac{y'^2}{a^2} = 1$. These

two are called *conjugate hyperbolas*, and have the same asymptotes as the original hyperbolas. These asymptotes have the following remarkable property: If (starting from G) the asymptotes be divided in continued proportion, and from the points of section lines be drawn parallel to the other asymptote, the areas contained by two adjacent parallels and the corresponding parts of the asymptote and curve are equal; also, lines drawn from the centre to two adjacent points of section of the curve enclose equal areas. The equation to the hyperbola when referred to the asymptotes is $xy = ab$; which shows that as the ordinates decrease in geometrical progression the abscissæ increase in the same ratio.

Hyperboreans (i.e. dwellers beyond Boreas or the North Wind), a name given by the ancients to a mythical people, whose land was generally supposed to lie in the extreme northern parts of the world. As the favourites of Apollo they enjoyed an earthly paradise, a bright sky, a perpetual spring, a fruitful land, unbroken peace, and everlasting youth and health. In the modern science of anthropology the term Hyperboreans is sometimes used to designate certain peoples, such as the Tchuktchis, Aino, Kamchadales, &c., who dwell in the north-east of Asia and the north-west and north of North America, and who cannot be classed either with the Indians or the peoples of the Asiatic plateau.

Hypericaceæ, or HYPERICINA, a natural order of about 300 known species, trees, shrubs, and herbaceous plants, widely distributed over the world, and in very different climates, but particularly numerous in North America. The species of *Vismia* yield a substance resembling gamboge. Many of the Hypericaceæ belong to the genus *Hypericum*, or St John's Wort (q.v.).

Hyperides (more correctly Hypericides), the Greek orator who, on the whole, ranks next to Demosthenes, excelling him in grace though inferior to him in moral power, was probably born about the same time as Demosthenes. By birth belonging to the middle class, he became a professional advocate, and earned large sums of money, which he spent with a generous hand alike on his private (somewhat scandalous) pleasures and on patriotic purposes. His *casuologia* against Philocrates assured his professional position and brought him on to the stage of politics, where he was destined to play a notable part (343 B.C.). From the first he was an opponent of the party which advocated peace with Philip, and a supporter of Demosthenes. The importance which attached to him as a politician at this time is shown by the fact that he was chosen by the Areopagus to represent the Athenian case before the Amphictyons in the dispute as to the control of the Delian temple. During all Demosthenes' manful struggles against Philip up to the fatal field of Chæronea, when, with the defeat of Athens, the political liberty of Greece practically came to an end and the supremacy of Macedonia was established, Hyperides

was the trusty and valuable supporter of Demosthenes. Even after the death of Philip, and during the early portion of Alexander's career, the two orators continued to be faithful allies. Only when Demosthenes endeavoured to follow an impossible *via media* in the matter of Alexander's absconding minister, Harpalus, did Hyperides break with his former leader, and head that accusation of bribery against Demosthenes which not only resulted in the banishment of the great orator but committed Athens to the fruitless revolt against Macedonia, known as the Lamian war. The leaders of this revolt were Leosthenes and Hyperides; the former perished in battle, the latter was put to death by Antipater (322 B.C.). It is remarkable that although Hyperides was admired and studied in Roman times, although his works were not only known to Photius in the 9th century but actually preserved in MS. in the King's Library at Buda until 1526, when Buda was taken by the Turks, it was not until 1847 that we had any specimens of Hyperides' oratory by which to judge for ourselves of his powers. In that year Mr A. C. Harris of Alexandria purchased a papyrus at Thebes containing portions of Hyperides' speech against Demosthenes and of his speech for Lycophron. At the same time Mr J. Arden was offered a papyrus, while he was travelling in Egypt, which turned out to belong to the same volume as that bought by Mr Harris, and to contain the remainder of the speech for Lycophron, and also the whole of the speech for Euxenippus. In 1856 another traveller, Mr Stobart, obtained from the same neighbourhood another papyrus containing the Funeral Oration of Hyperides. And in 1889 M. Eug. Revillout announced that the Louvre had on his proposition purchased a papyrus which contains fragments of the first speech against Athenogenes, and is much better calculated to give us an idea of the skill of Hyperides than anything acquired by England (*Revue des Etudes Grecques*, January-March 1889).

What most impresses one in reading Hyperides is his grace, next his indolence, and always his urbanity. His grace is nothing affected or assumed, nor is it useless ornament. Hyperides is a practical, not an epidemic orator, and means business. His grace is that of a man performing a feat well within his powers, and that not a despicable feat. At the same time he is indolent, apparently because there is really no need to exert himself. He will not take the trouble to pick and choose words; he makes the one that comes first—obsolete, obsolescent, proverbial, conversational, or what not do his work. He will not turn his sentences over mentally again and again before uttering them, so that they may roll out smooth, polished, balanced, and finished; he will rather let them come out at their own length, and as they list, he can pull them up at any time with effect and without effort. He is always transparent, never monotonous as is Demosthenes; he is witty to a degree, refined in his raillery, and his irony is delightful. Above all he never in his keenest attacks passes the bounds of good taste, as does Demosthenes. Finally, it must be remembered that what we possess cannot give us an adequate idea of the oratorical powers of Hyperides; of the speeches against Demosthenes and for Lycophron we only possess fragments; the speech for Euxenippus is indeed complete, but is never even mentioned by ancient critics, and therefore cannot have been one of his best productions. And as to the speech against Athenogenes, the anonymous writer of the treatise on the Sublime praises it indeed, but praises it as a pretty little speech. The best account of Hyperides is that given by Blass in his great work, *Die Attische Beredsamkeit*, III. ii. 1-72. Churchill Babington's

original edition of the Orations for Lycophron and for Euxenippus (Cambridge, 1853) will always be valuable. The best text of Hyperides' works is that of Blass in the Teubner series. See Hager's *Quaestiones Hyperidae* (Leip. 1870); and the *Quarterly Review* for April 1894.

Hyperion, a Titan, son of Uranus and Ge, and father of Helios, Selene, and Eos. Homer and later poets apply the name as a patronymic for Helios himself. Hence the attribute of beauty has been connected with the name, as in Shakespeare's 'Hyperion to a satyr.'

Hypersthene (Gr. *hyper*, 'above,' *stheneis*, 'strength'; so called to distinguish it from Hornblende, q.v., with which it was formerly confounded), a rock-forming mineral which crystallises in orthorhombic forms. It is an anhydrous magnesian silicate, containing a large percentage (15-24) of ferrous oxide with very little alumina. It is generally dark green or raven-black in colour, but has a pearly or metallic lustre when fractured across the cleavage-planes. This is due to the presence of very numerous minute brown scales of some foreign substance, which are arranged in lines along these planes. This mineral occasionally occurs massive, like hornblende, as in the island of St Paul on the Labrador coast. It is met with also as an occasional constituent of some eruptive igneous rocks, as in certain andesites and porphyrites, and in plutonic rocks, such as gabbro.

Hypersthénite, a more or less coarsely crystalline igneous rock allied to Gabbro (q.v.). It is an aggregate of labradorite (felspar) and hypersthene, and is of plutonic origin.

Hypertrophy (Gr., 'over-nourishment') is the term applied in medicine to the enlargement of certain organs of the body. The best examples of this change are seen in the muscular system, where it may occur altogether independently of disease. The huge bosses of flesh that stand prominently forward in the arm of a blacksmith or of a pugilist, and in the leg of an opera-dancer, are illustrations of hypertrophy where the general health may be perfect. In double organs, such as the kidneys and lungs, if the organ on one side degenerates through disease, the organ on the opposite side is often found to enlarge and carry on double work. In these cases hypertrophy is an effect of disease, but is at the same time a resource of nature to preserve life. There are, however, cases in which the hypertrophy has a hurtful instead of a conservative effect, as, for example, hypertrophy of the thyroid gland, constituting the disease known as goitre or bronchocele, hypertrophy of the prostate gland, of the spleen, &c. The following are, according to Paget, the conditions which give rise to hypertrophy: (1) The increased exercise of a part in its healthy function; (2) an increased accumulation in the blood of the particular materials which a part appropriates in its nutrition or in secretion; (3) an increased afflux of healthy blood. In hypertrophy of the muscular tissue the first and third of these conditions are present. In hypertrophy of the fatty tissue, constituting obesity, there is an excess of fat or of its chief elements in the blood.

Hypnasis. See SUTLER.

Hypnotism, or PSYCHO-THERAPEUTICS. From 1784, when Mesmer at Paris claimed the power of curing all manner of disease by 'animal magnetism,' this subject has been more or less tabooed by the medical profession. The nature of hypnotism and methods of inducing it are discussed at ANIMAL MAGNETISM. It is only within the last few years that it has received the scientific investigation which it deserves; but hypnotism

is now extensively used on the Continent in treating disease, and is slowly finding its way into practice in Britain. It is impossible to suppose that hypnotism will ever fulfil the sanguine expectations of many of its exponents, though it seems certain that it will render great aid as a therapeutic agent in treating some kinds of diseases. It is still necessary to write very guardedly upon the subject, as its action when used for the cure of disease is imperfectly understood; but that it is useful as a method of treatment is demonstrated by many cures which have been thoroughly investigated by the highest scientific men. Hypnotism is not any longer to be regarded as a mystery or as a superhuman gift, for its action can for the most part be explained by our present knowledge of physiology and psychology. The chief reason why hypnotism cannot be universally employed as a therapeutic agent is the fact that only a certain proportion of persons can be hypnotised. The proportion, however, of persons insusceptible to its power is much less than was at one time thought; and, when used therapeutically, somnambulism, the deepest stage of hypnotism, is not necessary. On the Continent it is found that about 80 per cent. of the inhabitants can be hypnotised.

Hypnosis may be used in two ways in relation to disease. In the first place, simple sleep is induced, and sleep when produced without the action of drugs is often of great importance, and of itself aids in treatment. Again, in many cases when the person is asleep, suggestions may be made to him which will abolish pain, and which in some diseases will bring about either the relief of symptoms or the cure of the disease. Every one knows that the mind influences the body, and that concentrated thought can bring about sensations in various localities. It is upon this knowledge that the hypnotist bases his practice. The patient being placed in a hypnotic sleep, his attention is directed to various parts of the body, and very often the effect is increased through local stimulation by means of passes or rubbing. During the hypnotic sleep the patient is uninfluenced by his surroundings, and therefore he is all the more open to suggestions, and no disturbing influences diminish his powers of concentration. By means such as these neuralgic or rheumatic pains may frequently be removed; headaches may often be cured, and so may some forms of dyspepsia, as well as the various manifestations of hysteria and hypochondriasis, and even functional paralysis. It is found, too, that hypnotism is useful in dipsomania and in treating persons addicted to opium eating and other depraved tastes. At present it cannot be said that hypnotism is of use in any disease having an organic origin, although in such diseases various symptoms, especially those of pain, may be removed successfully. It is quite possible for operations to be performed upon persons under the hypnotic influence without the slightest pain being felt by the patient; but as various other anaesthetics are more easily employed, it is only in a few cases where these are contra-indicated that hypnotism will be used in this connection.

For educational purposes it is held possible to impress a person in the hypnotic sleep with ideas which will modify his usual character. For instance, it seems possible in many cases to cure persons of bad habits, such as stealing, lying, or the excessive use of alcohol; and on the Continent attempts are being made to influence habitual criminals for good by means of hypnosis. Young children, defective in brain power or constitutionally vicious, may be improved by careful hypnotic treatment. It is a mistake to suppose that hypnotism can only be used successfully in treating nervous or hysterical persons. Such

people are often difficult to hypnotise, and there is always a danger of either increasing their troubles or in some cases of inducing insanity. Ordinary individuals, especially those who have learned to obey, are the subjects whom a hypnotist would prefer to treat. Children at school, soldiers and sailors, and officials of all ranks, are the classes from which the most brilliant successes have been obtained hitherto in treating disease. In many cases of insanity hypnotism may be used with advantage as a therapeutic agent, although its employment in these cases is not by any means easy. Persons suffering from hallucinations, it is said, have been cured, and those who suffer from the painful result of some grievous trouble have been restored by having the incident blotted out from their memory.

Although hypnotism has power for good when properly used by medical men, it is an exceedingly dangerous weapon in the hands of the unskilful or unscrupulous. All public exhibitions of hypnotism should be prohibited by law, as persons experimented upon have been rendered lunatics, or had their nervous systems severely damaged. Crimes have been committed by persons who have been hypnotised. Just as a person when hypnotised is rendered extremely impressionable, and therefore capable of receiving beneficial suggestions, so he is nearly as liable to receive suggestions for evil; and it is quite possible for him during the hypnotic sleep to be impressed with the belief that he is to commit some act after he has awakened from the sleep—an act he is safe to do, acting at the time as an automaton. It is absolutely impossible for a person to be hypnotised unless he has the idea of what is going to happen. It is a psychical and not a physical influence which brings about the condition. Only persons whose will-power is weakened by fear, or by the idea of a supposed power which influences them in spite of themselves, can be hypnotised without full consent on their part; but the oftener a person is hypnotised the more easily may he be subsequently affected.

See Bernheim, *Suggestive Therapeutics* (trans. by Herter, 1889); Tuckey, *Psycho-therapeutics* (3d ed., 1891); and other books on hypnotism by Bjornstrom (1889), Kingsbury (1891), Comrnelles (1891), Vincent (1893), and Hart (denouncing it as witchcraft, 1894); and the article CHARCO.

Hypnotics. See NARCOTICS, SLEEP.

Hymnum, a genus of mosses belonging to the order Bryineæ. Archegonia and capsules are borne on special lateral branches. The sexual organs are formed in August and September, and the capsules take from ten months to a year to ripen. Many species are remarkable for their beauty, and are often used for decorative purposes. Their distribution is universal.

Hypocaust, a form of furnace used by the Romans for the purpose of heating baths and apartments. It was placed in a chamber beneath the floor, and the heated air and products of combustion were made to circulate round the walls and under the floor by means of hollow tubes or a hollow lining, and were also carried in pipes to other rooms. See BATHS.

Hypochaeris, a genus of plants of the natural order Compositæ, sub-order Cichoroacæe, of which one species, *H. radicata*, or Long-rooted Cat's ear, is extremely common in meadows and pastures in Britain. Its leaves spread on the ground, and resemble in form those of the dandelion, but rough; the stem is branched, the flowers not unlike those of the dandelion, but smaller. Cattle eat this plant readily, and its abundance is not deemed injurious to pasture or fodder.

Hypochlorous Acid. HOClO , is the acid contained in bleaching powder. It can only be obtained as a dilute solution, as in the concentrated state it is very liable to decomposition. It is a powerful bleaching agent, and forms a series of salts, *hypochlorites*, which also possess bleaching properties. The chief of these are the hypochlorites of lime and soda. The lime salt is the important constituent of bleaching powder, while the soda salt is prepared commercially by passing chlorine into a solution of soda. For further information, see BLEACHING POWDER. *Hypo*, in composition (Gr. "under"), is used much like *sub*, from Latin. Hypochlorous acid has less oxygen than chlorous acid; hyposulphuric has less oxygen than sulphuric, but more than sulphurous acid. Hypophosphates are salts formed by hypophosphoric acid and a base.

Hypochondriasis (so called from its supposed connection with the hypochondriac regions of the Abdomen, q.v.), a disease characterised by extreme increase of sensibility, palpitations, morbid feelings that simulate the greater part of diseases, exaggerated uneasiness and anxiety, chiefly in what concerns the health, &c. In extreme cases it becomes a species of melancholia. The disease is intimately connected with, if not caused by, disorder of the digestive functions. See INDIGESTION, INSANITY.

Hypodermic Injection. This method, first introduced by the late Dr. Alexander Wood of Edinburgh, is an extremely valuable one in certain cases, though its applicability is limited. It consists in the injection of a solution of the substance to be given beneath the skin, by means of a fine hollow needle to which a small syringe is attached. The prick given by the needle is much less acutely felt by the patient if the needle be lubricated with carbolic oil or the like. Absorption from the subcutaneous tissue takes place speedily, and is not interfered with by vomiting, or other conditions of the stomach which may delay or prevent the entrance of the remedy into the system by that channel. The action of the drug is thus at once more rapid and more certain than when administered by the mouth; and a smaller dose is required. Only such substances as can be given in small bulk and in an unirritating condition are available. It is thus chiefly of use for the vegetable alkaloids, of which morphia is far the most often employed. It need hardly be said that it is to be used only by skilled hands. The same method is largely employed in experiments on the action of disease poisons in animals, and in Pasteur's treatment of hydrophobia; see also DIPHTHERIA, TETTERLE.

Hypos tasis, the Greek term used to designate the distinct subsistence of the three persons of the Trinity (q.v.).

Hypothec, a term in the law of Scotland, but not used in England, to denote a lien or security over goods in respect of a debt due by the owner of the goods. Thus, a law-agent or attorney has a hypothec over the title-deeds of his client in respect of his account or bill of costs; and the landlord of agricultural subjects held under leases current at the 11th of November 1881 has a hypothec over the furniture or crops of his tenant for the current rent. The Hypothec Abolition (Scotland) Act, 1880, did away with the landlord's hypothec for the rent of all other land exceeding two acres let for agricultural purposes. See LANDLORD AND TENANT.

Hypothense, the name of that side in a right-angled triangle which is opposite to the right angle. The well-known property of the hypothense, that the square described on it is equal to the sum of the squares described on the

other two sides, is proved in the 47th proposition of the first book of Euclid's *Elements*.

Hyracotherium, a genus of fossil ungulates, established in 1839 by Owen for a small Eocene animal about the size of a hare, to which, however, he afterwards gave the name of *Phiolophus*. See HOARSE.

Hyrax, a genus of mammals representing a distinct order, the affinities of which are very obscure, and unilluminated by the discovery of any fossil forms. "Feddle folk" as the species of hyrax (so-called "cony") are, they find, according to

many, their nearest allies in the huge elephants or in the ungulates proper. In size they are like rabbits; but the name "cony," which really belongs to the rabbit, is not very appropriate; in appearance they rather suggest marmots. They are natives of

Hyrax sylvaticus.

Africa and Syria, and live among the rocks, in stony deserts, or on trees. The plump body, thick head, small ears, short slender limbs, rudimentary tail, soft yellowish gray or brownish fur are obvious external characteristics. Closer examination shows many peculiarities. The snout, which has a cleft upper lip, is somewhat rodent-like, and so are the rootless, persistently growing curved upper incisors, except that they have a prismatic shape and a sharp point instead of the chisel edge of rodents. The entire dentition is expressed in the formula $\frac{2.1.1}{1.1.1}$, and the back teeth are in pattern distinctly like those of the rhinoceros and some other ungulates. There are four toes on the anterior limbs, three on the hind, all with short broad nails except the inner toe of the hind-foot, which bears a curved claw. The feet strikingly suggest those of rhinoceros or tapir, and are interesting in the further peculiarity that the naked sole is furrowed in such a way that the hyrax can in gecko-like fashion cling to the vertical sides of rocks and trees. Among the many characteristics of the skeleton may be noticed the large number (28-30) of back and loin (dorso-lumbar) vertebrae. The brain and skull most resemble those of ungulates; the stomach recalls that of horse or rhinoceros; the placenta is zonary as in elephants and carnivores.

There are numerous species, sometimes referred to two genera, *Hyrax* and *Dendrohyrax*. The former is represented by *H. capensis*, the Cape Damian, Klippdass, or Rock-badger; *H. sylvaticus*, the Shaphan (mis-translated "cony" of Scripture); and *H. habessinicus*, the Ashtok of the Abyssinians. These live in companies, usually in holes among the rocks, and feed on shoots, grass, flowers, and the like. In reference to the Scripture account it may be noted that the hyrax does *not* chew the cud, though it moves its jaws very constantly. Though only two are born at a birth, the rate of multiplication is very rapid, keeping pace with ravages of carnivores, which are very deadly in spite of the caution and even sentinels of the hyraxes. Of different habit, and sometimes referred to the second genus, *Dendrohyrax*, are certain hyraxes which, in West and South Africa, live in trees, e.g. *D. arboreus* and *D. dorsalis*. The members of this order, so puzzling zoologically, are playful, good humoured, and wary.

Their flesh is sometimes eaten, and is said to resemble rabbit's.—*Hyrcanium*, a supposed medicine for certain nervous diseases, was made from the mixed urine and feces of the Cape Hyrax.

Hyrcania, an ancient district of Asia, of indefinite extent, bordered on the Caspian Sea (sometimes called *Hyrcanica Mares*) and the river Oxus. It corresponded with the modern Mazanderan and Asterabad.

Hyrcanus, the name of two Jewish high-priests and princes of the Hasmonean family (see MACCABEES). (1) JOHN HYRCANUS, son of Simon Maccabæus, who ruled 135-105 B.C., was at first tributary to the Syrians, but on the death of Antiochus made himself independent, subdued the Samaritans on the north, and forced the Idumæans on the south to adopt the laws and customs of the Jews. He also concluded an alliance with the Romans, and extended his territories almost to the ancient limits of the Davidian monarchy. Originally a Pharisee, he subsequently attached himself to the party of the Sadducees, who were anxious to keep on good terms with the Romans, and who discountenanced the turbulent religious patriotism of the Jewish masses. Hyrcanus was, comparatively speaking, a just and enlightened ruler, and the country enjoyed great prosperity during his reign. He left five sons, two of whom, Aristobulus and Alexander, governed with the title of king.—(2) HYRCANUS II., son of Alexander, and grandson of the preceding, was a feeble prince. On the death of his father (78 B.C.) he was appointed high-priest by his mother Alexandra, who ruled Judæa herself for the next nine years. After her death (69 B.C.) his younger brother, Aristobulus, a braver and more energetic man, seized the government, and forced Hyrcanus to withdraw into private life. He failed to win back his dominions, until Pompey began to favour his cause. After some years of tumultuous fighting, Aristobulus was poisoned by the partisans of Ptolemy (49 B.C.), and Hyrcanus for some time possessed the dignity of high-priest. Caesar (47 B.C.), on account of the services rendered to him by Antipater of Judæa, made the latter procurator of Judæa, and thus left in his hands all the real power. Antipater was assassinated, and Antigonus, son of Aristobulus, with the help of the Parthian king, invaded the land, captured Hyrcanus by treachery, cut off his ears, and carried him off to Seleucia on the Tigris. Some years later Herod, son of his old friend Antipater, obtained supreme power in Judæa, and invited the aged Hyrcanus home to Jerusalem. He was allowed to depart, and for some time lived in ease and comfort; but, falling under suspicion of intriguing against Herod, he was put to death, 30 B.C.

Hyslop, JAMES, poet, was born in the parish of Kirkcubright, Dumfriesshire, July 23, 1798. While acting as a shepherd near Aird-moss, Ayrshire, the scene of a Covenanting skirmish and Cameron's death (1680), the traditions of the district stimulated his imagination to the writing of his best-known poem, 'The Cameronian's Dream,' which appeared in the *Edinburgh Magazine* (1821). Hyslop, who had prepared himself by persevering private study for teaching at Greenock, through the influence of Lord Jeffrey was appointed tutor on board the *Doris*. While tutor on board the *Three* man-of-war he died of fever at St. Jago, Cape Verd Islands, November 4, 1827. An edition of his poems was printed from his manuscript book by the Rev. P. Meares, Coldstream (Glasg. 1887). Mr Hamish McCum set his 'Cameronian's Dream' to music in 1889.

Hyssop (*Hyssopus*), a genus of plants of the natural order Labiate, distinguished by four

straight diverging stamens, and a calyx with fifteen ribs. The known species are few. The Common Hyssop (*H. officinalis*) is a native of the south of Europe and the East. It is found on the Alps of Austria. It is a half-shrubby plant, about 1½ feet high, the upper part of the stems quadrangular, the leaves evergreen and lanceolate, the flowers in one-sided whorled racemes. The flowers are generally of a very beautiful blue. It has an agreeable aromatic odour. It has long been in cultivation for the sake of its leaves and young shoots, which are sometimes used for culinary purposes as a seasoning, but more generally in a dried state as a stomachic and carminative. A syrup made with them is a popular remedy for colds. The virtues of hyssop depend on a volatile oil. The hyssop of the Bible has been supposed to be some species of *Phytolacca* (q.v.), as *P. acinosa*, a native of the Himalaya; but on the authority of Dr Royle it appears to have been the common Caper (q.v.). Hedge Hyssop is *Gratiola officinalis*. See GRATIOLE.

Hysteria (Gr. *hystera*, 'the womb') derives its name from an ancient but erroneous notion that it is specially connected with disorders of the womb. It is a disease which exhibits itself under so many aspects that to describe all the varied forms which it may assume would be to give an epitome of the symptoms of nervous diseases in general, for there is hardly one of these which the mimicry of hysteria may not reproduce. In dealing with the condition two things must be kept in mind—the tendency or temperament which predisposes to it, and the exciting cause which determines the actual attack. Among savages it is scarcely ever met with. Among civilised races it is unequally distributed, the French, for example, being more hysterical than the English, while in every country the female sex, especially at or before the age of puberty, is far more liable to it than the male. Among boys, however, it is not uncommon. The tendency seems sometimes to be due to hereditary influence, sometimes to injudicious training in childhood. The exciting cause which develops the hysterical tendency into actual hysteria is generally some severe emotional shock—a fright, an unhappy love affair, or a sudden reverse of fortune. But many general diseases occasionally carry hysteria in their train; and in 1889 a volume of nearly 400 pages appeared (*The Exciting Causes of Hysteria*, by Georges Gaiñon) dealing solely with the enumeration and discussion of the exciting causes of this Protean malady. In the developed disease some of the symptoms are continuous, others occasional or paroxysmal. The will is weakened, and the patient is a prey to unregulated whims and impulses. The temper is often irritable, and every petty annoyance is exaggerated into a serious trouble. There is a morbid craving for sympathy, which leads to the most outrageous acts. Blood has been swallowed by a hysterical girl in order that she might vomit it again. Porter has been mixed with urine, and

Common Hyssop
(*Hyssopus officinalis*).

the mixture palmed off upon the medical man as an abnormal discharge. The most elaborate lies have been concocted; innocent people have been accused of imaginary crimes; every inconvenience has been suffered and every artifice exhausted in order to play upon the credulity or the pity of friends and attendants.

This moral perversion has its counterpart in the disorder of the sensory and motor mechanism. Sensibility to impressions of various kinds may be exalted, lessened, or abolished. A touch may give rise to all the symptoms of severe pain; and, on the other hand, the prick of a pin, or even the contact of a hot iron, may not be felt. Paralysis of the legs, arms, or face, or of one side of the body, or of special muscles or groups of muscles, is a very common symptom. Laryngeal paralysis may reduce the voice to a whisper. Speech or motor power may often return suddenly, especially under the influence of strong emotion; and there is no doubt that 'miraculous' cures are sometimes of this nature. A hysterical paralytic, for instance, will generally run out of a burning house. Digestive disorders are common in hysteria, and, aided sometimes by fraud, give rise to 'fasting girls' and other newspaper marvels. Palpitation, great rapidity of breathing, giddiness, and flushing of the face are also of frequent occurrence.

But besides these more or less continuous symptoms, there are the occasional paroxysms or 'fits' which in the popular mind are chiefly associated with the name of hysteria. These emotional storms or crises vary much in frequency and severity. In the mildest form there is no loss of consciousness, but the arms, legs, and head are tossed about, and there is great mental excitement. In severer cases, perhaps after some premonitory symptoms, such as the sense of constriction in the throat known as the *globus hystericus*, the patient falls to the ground, sometimes with a scream, her features twitching, her back arched, and her legs and arms moving convulsively. She may snap like a dog at the hands of those who approach her, or at her own, occasionally inflicting serious injuries; but she rarely hurts herself in falling, as often happens in an epileptic fit. The seizure may last only a fraction of a minute, or as long as three or four hours.

The treatment of hysteria must be directed both to the removal or alleviation of the symptoms and to the cure of the condition which gives rise to them. The first object can generally be attained, the second more rarely. The treatment must be both moral and physical, and the former is the more important of the two. In the more severe cases complete change of scene and surroundings is required. The patient should be placed among strangers, and away from the sympathising friends whose well-meant 'coddling' and condolence are often the chief hindrances to recovery. The nurse must be kind but firm; and while the morbid tendencies of the patient are repressed, she must not be laughed at but understood, and encouraged to make essays in self-control. As an alternative to sending the patient away from home, the Weir-Mitchell treatment has met with much success. The patient is kept in bed, isolated except from the attendant, and fed with abundance of easily-digested food, electricity and massage being applied daily.

Particular symptoms must be treated on general principles. Forced feeding by means of a stomach-

tube may be required if the appetite is gone or the patient refuses food. A mixture of milk, eggs, meat, and the flour of lentils has been used for this purpose with success. Of late hypnotism has been much employed in France for the treatment of hysterical affections; but this is a method which should be used with caution, for it sometimes aggravates the condition which it is intended to cure.

For prevention of the 'fits' the most useful drugs are valerianate of zinc, iron, morphia, and turpentine. Slight attacks may be warded off by an antispasmodic like ether, or by inhaling nitrite of amyl. To cut short an attack after it has begun a copious douche of cold water to the head is an old and approved plan. A still more effectual proceeding is to close the mouth and nose with a towel for fifteen or twenty seconds. A little cold water poured into the mouth often acts at once. When everything else fails, $\frac{1}{2}$ th to $\frac{1}{4}$ th of a grain of apomorphine, injected under the skin, will end the fit (Gowers).

People with a tendency to hysteria should be encouraged to substitute some rational and regular work for the aimless life of alternate excitement and lassitude which so many of the women of the upper and middle classes lead.

Hystrix. See PORCUPINE.

Hythe, a parliamentary and municipal borough and market-town of Kent, 5 miles WSW. of Folkestone, 15 miles S. of Canterbury, and 67 SE. by E. of London by rail, is one of the Cinque Ports (q.v.), although in actual locality Lympne or Lynton (the ancient *Portus Lemannis* of the Romans), now some three miles inland, was probably the original harbour. The town, which is pleasantly situated some distance from the sea, is built on the side of a hill, from the top of which an extensive view over the Romney marsh is obtained. Its church, a cruciform building of great beauty, in part Romanesque, has been restored since 1866, and contains in a crypt underneath the chancel an extraordinary collection of human skulls and bones—many of the skulls having deep cuts in them—the age and origin of which are altogether uncertain. Near to Hythe are the headquarters of the School of Musketry and Shorncliffe camp, both established in 1854; the picturesque ruins of Saltwool Castle, with memories of Becket; and the Royal Military Canal, 23 miles in length, constructed in 1805 for the conveyance of military stores to Rye, but never of much use, and now entirely superseded by the railway. In 1881 a sea-wall and parade, extending from Hythe to Sandgate (q.v.) and Folkestone (q.v.), was opened. These and some smaller places are included in the parliamentary borough of Hythe, which since 1832 has returned only one member. Pop. of that borough (1851) 13,164; (1891) 35,547, of whom 4347 were within the municipal limits, which include West Hythe. In 1295 the French made a descent on Hythe, but were decisively repulsed, and later on, towards the end of the reign of Richard II., the town was visited with a threefold calamity, a fire having destroyed 200 houses, a pestilence carried off numerous inhabitants, and an unusually heavy storm caused a severe loss of men and ships. Several charters are preserved at Hythe, amongst them its earliest charter of incorporation granted in 1575. See Montagu Burrow's *Cinque Ports* (1888).

I

the ninth letter in the alphabets of western Europe, was called *iota* by the Greeks, from its Semitic name *yod*. Hence, owing to the character being the smallest in the Hebrew alphabet, we get the word *jot*, 'a tittle' (St Matt. v. 18), and *jottings*, or 'small notes.' The name *yod* meant a hand, the form of the character in the Egyptian Hieratic, from which the Phœnician alphabet was derived, bearing some resemblance to a hand, with the thumb held apart from the fingers (see ALPHABET). In early Greek inscriptions the form of the letter was angular, something like our Z; it then came to resemble S, and this, about the 7th century B.C., was straightened out into a vertical stroke. It has since varied less in form than any other letter. The dot in our minuscule *i* first came into use in the 11th century A.D. It was originally an accent, *i*, and was only employed to distinguish *ii* from *u*, or to mark the *i* in the combinations *ui* and *iu*. In the 12th century the accent began also to be used when *i* was in juxtaposition with *m* or *n*. It only became universal after the invention of printing, when it was found inconvenient to use two forms of type. In the 14th century a dot began to be substituted for the accent, the oldest MS. in which the dot is found dating from 1327. These distinctions may seem trivial, but are very useful in determining the dates of mediæval MSS.

In Italian, and in most European languages, the sound of the letter is that of the Latin long *i*, the name-sound of our *e*, which we have in the English words *machine* and *machine*. The long *i* in Latin was always thus pronounced, and never like *i* in *fine*. The name-sound of our *i*, which is really a diphthong, is only heard in words where it is supported by a subscript *e*, as in *bite*, *pipe*, *aiue*, or where it is followed by an old guttural, as in *high*, *might*, *light*. This became the name sound because the pronoun *i* (A.S. *ie*, Ger. *ich*) was originally followed by a guttural which has now fallen out. The normal sound of *i* in English is that heard in *bit*, *dip*, *sit*, which is the short Latin *i*. This sound is represented by *y* in *equal*, by *u* in *busy*, by *o* in *woman*, by *ei* in *forfeit*, by *ie* in *siere*, by *ui* in *quilt*, by *ie* in *beeches*, and by *ui* in *carriage*. See J.

Iago. See JAMES, and SANTIAGO.

Iambic Verse, a term applied, in classic prosody, and sometimes in English, to verses consisting of two syllables, of which the first is short, and the second long (—). Archilochus (q.v.) is the reputed inventor of iambic verse. The English language runs more easily and naturally in this metre than in any other. Thus, our usual blank-verse line consists of five iambses, while we have also such combinations of continuous rhyming metres in iambic measure as tetrasyllabics; lines of six syllables and three accents (Skeltonical verse); octosyllabics, as in most of the old romances, *Hudibras*, *Lalla Rookh*, and most of Scott's and Byron's romantic poems, except *Lara* and the *Corsair*;

decasyllabics, with five accents, which when rhyming in couplets forms our so-called heroic metre; and Alexandrines, or twelve-syllable metre with six accents, as in Drayton's *Polygobion*. See METRE.

Iamblichus, a Neoplatonist philosopher, a native of Chalcis, in Cæle-Syria, who died about 330 A.D. He was a pupil of Porphyry, and follower of Plotinus; but in his hands the Neoplatonist philosophy degenerated into theurgy and demonology, while among his disciples his reputation spread as a conjuror and miracle-worker. His writings included a life of Pythagoras, and treatises on mathematics and philosophy; the authenticity of the treatise on Egyptian mysteries (ed. Parthey, 1857) is more than dubious. See NEOPLATONISM.

Ianthina, a genus of gregarious, pelagic gasteropods, in the same division as the river snail (*Paludina*), *Trochus*, *Turbo*, &c. The shell is snail-like, but delicate, translucent, and blue in colour. In the warmer seas the animal floats by expanding its 'foot' on the surface, and is drifted about by currents, occasionally on to British shores.

Common 'Violet Snail' (*Ianthina fragilis*): Shell, animal, and raft.

It is most remarkable for an airy raft which it secretes, and eventually sets adrift, laden with egg-capsules, like those of the whelk. The animals exude a violet secretion, and seem to feed on *Volvella* and other Cœlenterates of the Portuguese man-of-war type.

Iapygia. See APULIA.

Ibarra, capital of Iurbabura province, Ecuador, has a pop. of about 10,000.

Ibea, or I.B.E.A. See ZANZIBAR.

Iberia, the name by which Georgia (q.v.) was known to the Greeks and Romans; and also an ancient name for Spain. The question of an Iberian race is discussed at BASQUES, Vol. I. p. 781.

Iberis. See CANDY FLUT.

Ibex, a name given to several species of the genus *Capra*, of which the best known is the Alpine ibex (Ger. *Steinbock*, Fr. *Bouquetin*). The various species are described at GOAT.

Ibis, a genus of birds related to the Spoonbills, and, more remotely, to the Storks and Herons. It comprises about twenty-five species, of which the bulk belong to the Old World, though the genus is nearly cosmopolitan. The bill is long, slender, curved, thick at the base, the point rather obtuse, the upper mandible deeply grooved throughout its length. The face, and generally the greater part

of the head, and sometimes even the neck, are destitute of feathers, at least in adult birds. The plumage is mainly white, with black primary feathers and plumes on the wings. The neck is long. The legs are rather long, naked above the tarsal joint, with three partially united toes in front, and one behind; the wings are moderately long; the tail is very short. The Sacred Ibis, or Egyptian Ibis (*I. aethiops*; formerly known as *I. celestis*), is an African bird, 2 feet 6 inches in length, although the body is little larger than that of a common fowl. The Glossy Ibis (*I.* or *Plegadis falcinellus*) is a smaller species, also African, but migrating northwards into continental Europe, and occasionally seen in Britain. It is also a North

The Sacred Ibis (*Ibis aethiops*).

American bird. Its habits resemble those of the sacred ibis. Its colour is black, varied with reddish-brown, and exhibiting fine purple and green reflections. It has no loose pendent feathers. The White Ibis (*I.* or *Eudicranus alba*), a species with pure white plumage, abounds on the coasts of Florida. The Scarlet Ibis (*I.* or *Eudicranus ruber*) is a tropical American species, remarkable for its brilliant plumage, which is scarlet, with a few patches of glossy black. The Straw-necked Ibis (*I.* or *Carphibis spinicollis*) is a large Australian bird of fine plumage, remarkable for still naked yellow feather-shafts on the neck and throat.

The Sacred Ibis, one of the birds worshipped by the ancient Egyptians, and called by them *Hab* or *Hib*, was supposed, from the colour of its feathers, to symbolise the light and shade of the moon. It was the avatar of the god Thoth or Hermes, who escaped in that shape the pursuit of Typhon. Its feathers were supposed to scare, and even kill, the crocodile. It appeared in Egypt at the rise and disappeared at the inundation of the Nile, and was said to deliver Egypt from the winged and other serpents which came from Arabia. As it did not make its nest in Egypt it was believed to be self-engendering, and to lay eggs for a lunar month. It was celebrated for its purity, and only drank from the purest water; besides which, it was fabled to entertain the most invincible love of Egypt, and to die of self-stayation if transported elsewhere. Its flesh was thought to be incorruptible after death, and to kill it was punishable with death. Ibises were kept in the temples, and unmolested in the neighbourhood of cities. After death they were mummied, and there is no animal of which so many remains have been found at Thebes, Memphis, and some other places. They were prepared as other mummies, and wrapped up in linen bandages, which are sometimes plaited in patterns extor-

nally. See Wilkinson, *Manners and Customs*, and Renouf's *Hibbet Lectures* (1880).

Iblis. See DEMONOLOGY.

Ibn Batuta. Arab traveller and geographer, whose proper name was Abu Abdullah Mohammed, was born at Tangiers in 1304, and spent thirty years (1325-54) of his life in travel. Settling at Fez, in Morocco, in 1354, he wrote the history of his journeys, and died there in 1378. The course of his travels led him first to Mecca, then to Persia, Mesopotamia, Arabia, the east coast of Africa, Asia Minor, the Caspian regions, Khwarizm, Bokhara, Afghanistan, and India; thence he proceeded to China by way of Sumatra, and finally came home to Fez in 1349. But his journeys were not yet done. He visited southern Spain, and then travelled as far as Timbuktu on the Niger. His narrative is extremely interesting, humour and anecdote alternating with graphic description, and through it all runs the golden thread of the writer's naive personality. It was published with a French translation, in 4 vols., by Defremery and Sanguinetti in 1858-59 (3d ed. 1893). See *National Review*, July 1888, and *Sent. Geog. Mag.*, September 1888.

Ibsen. HENRIK, poet and the creator of a new type of drama, was born at Skien in south Norway, 20th March 1828. In 1842 he was apprenticed to a chemist at Grimstad. But he aimed higher; he studied, and wrote poetry and a drama, *Godlium*. This, published in 1850, was a failure. In the same year he became a student at Christiania University, but soon grew tired of academic study. After nearly two years of journalistic work he was appointed director of Ole Bull's theatre at Bergen. For it he wrote five romantic dramas, but only two—*Lady Ingevald Ostrit* and *The Banquet at Solhøng*—have been published. In 1857 he undertook similar duties for the National Theatre in Christiania. His next dramas were *The Warriors in Helgeland* (1858), *The Rural Kings* (1864), and *Luce's Comedy* (1862). The first two admirably reproduce the style and spirit of the old sagas, and placed Ibsen in the first rank of Scandinavian dramatists. The last is a precursor of his satirical social dramas; it set all the Philistine world of Norway against him. Then in 1862 the National Theatre became bankrupt; and, moreover, Ibsen was bitterly disappointed when Norway held aloof from the Danes in their struggle against the German powers. So, thoroughly disgusted with his countrymen and his country, he said good-bye to Norway in 1864 and lived chiefly in Rome, Dresden, and Munich till 1892, when he returned to Christiania. The Norwegian parliament granted him, reluctantly—a pension in 1866. In that and the following year appeared the lyric dramas *Brand* and *Peer Gynt*, in many respects the finest things he has done; the poetic workmanship is of a very high order. Brand is an incarnation of the absolute sense of duty, but his ideal striving and self-sacrifice end in disaster because he is ignorant of the proper function of love. Peer Gynt is the complete mirror of actual man; in his case self-hood and romantic fancy are the rocks upon which ideal striving comes to nought. By intention peculiarly representative of Norwegian character, both dramas have also a universal validity. In 1873 Ibsen published the double drama *Emperor and Galilee* (Julian and Christ; Eng. trans. 1876), in which he foretells the 'third kingdom' that is to transcend both classic and Christian culture. But already in 1869

he had finished *The Young Men's League*, another of the satirical social dramas which have made his name famous. This has been followed by *Pillars of Society* (1877), *A Doll's House* (1879), *Ghosts* (1881), *An Enemy of the People* (1882), *The Wild Duck* (1884), *Rosmersholm* (1886), *The Lady from the Sea* (1888), *The Master Builder* (1892), &c. The *Digte* (2d ed. 1875) are lyrics and epics.

These plays aroused a storm of controversy in England in 1889, as they had done shortly before in Germany and in the Scandinavian countries. Ibsen is a passionate advocate of individual liberty. He maintains that man's first and chiefest duty is to be wholly man, consistent with himself in all things. An idealist of the highest type in the beliefs he entertains as to the future possibilities of mankind, he is a sceptic in his estimation of existing men, and especially of existing institutions, social and political. His mission, like Socrates' of old, is to awaken men to a real comprehension of themselves. Thus he is an uncompromising moral reformer. He is inspired by a stern Semitic earnestness, and drives right through all obstacles to get grasp of truth unmistakable. The interest and method of his plays are almost exclusively psychological. He makes the consequential development of character the supreme law of dramatic evolution. His plays represent the conclusion from the psychological premises of some problem in character or social circumstance. Each play begins where an ordinary play would be just on the point of ending; the situation is completely formed before the curtain rises. By his analytic method Ibsen is enabled to paint richly-detailed pictures of inner soul-life without resorting to long monologues or explanatory speeches. His language is concise and vigorous, and full of vivid realism. He gets some of his effects by the use of incisive sarcasm and tragic irony and fearless outspoken realism. His characters are real persons: each in thought, language, and behaviour presents a consistent individuality throughout. There is at times too much mysticism and symbolism, and a tendency to exaggerate contradictions of character and overburden the action with motives.

Henrik Ibsen (1858), in commemoration of his 70th birthday, is a collection of opinions, criticisms, and of reminiscences by Scandinavian authors, edited by Gerhard Gran. See biographies by Vasenius (Swedish, 1883), Passage (German, 1883), Jæger (Norwegian, 1888; Eng. trans. 1891), and in G. Brandes' works (Danish, 1883). In English, Mr Gosse's articles (in *Fortnightly*, 1889, &c.); Wicksteed's *Four Lectures on Ibsen* (1892); G. Bernard Shaw, *The Quotations of Ibsenism* (1893); H. H. Boyesen, *A Commentary on the Works of Ibsen* (1894); and Archer's translation of the prose works (1899). Brand has been translated both in prose and verse.

Ibycus. Greek lyric poet, a native of Rhegium, in Italy, flourished about 510 B.C., and lived some time at the court of Polycrates, tyrant of Samos. According to the legend he was slain by robbers near Corinth, and dying called upon a flock of cranes that he saw flying overhead to avenge him. The cranes went and hovered over the theatre at Corinth, where the people were assembled. One of the murderers, seeing them, exclaimed involuntarily, 'Behold the avengers of Ibycus.' This led to an inquiry, and to the conviction of the guilty. The story is best told in Schiller's beautiful ballad. Ibycus wrote chiefly erotic poetry. The fragments that survive are printed in Bergk's *Poetae Lyrici Graeci* (vol. iii.) and in Schneidewin's *Delicatus Poesis Graecorum Elegiacae* (1839).

Ica, a department on the coast of Peru, with an area of 8400 sq. m. and a pop. of over 60,000. The greater part is a sandy desert, but the river valleys are fertile, and are planted with corn, fruits, cotton, and indigo. In one of these valleys lies the capital,

Ica, 50 miles SE. of Pisco, its port, with which it is connected by railway. Pop. 7000.

Icarus. See DEDALUS.

Ice is water in the solid form. It is specifically lighter than water which is just about to freeze, and therefore swims in it. Water, in becoming solid, expands about $\frac{1}{11}$ th in volume or bulk, and thus acquires a density equal to 0.91674 (water at 0° C. = 1.00). The formation of ice takes place generally at the surface of water. This is owing to the peculiarity that, when water has (at the ordinary atmospheric pressure) cooled down to within 3.9° C. of freezing, it ceases to contract as it did before with increase of cold, and begins to expand until it freezes (see HEAT); this causes the coldest portions of the water to be floating always on the surface. In some circumstances, not very well explained, ice forms at the bottom of rivers, and is called ground-ice or Anchor-ice (q.v.).

Water in ordinary cases freezes at the degree of temperature marked 0° on the Centigrade and Réaumur's thermometers and 32° on Fahrenheit's; but if it is kept perfectly still it may be cooled to nearly -5.5° C. below freezing (= 22° F.) and still remain liquid. The least shake, however, or throwing in of a solid body, makes a portion of it freeze instantly, and its temperature rises immediately to 0° C. Sea-water, and salt water in general, freezes at a lower temperature than pure water; in doing this part of the salt separates, and the ice, when melted, gives water that is fresher than that on which the ice was formed. The colour of pure ice is deep blue, which is only discernible, however, when it is in large masses; it is best seen in the clefts of a glacier or of an iceberg. In order to melt a pound of ice it is necessary to communicate to it as much heat as will raise 80.025 lb. of water 1° C. This measures the 'latent heat' of ice; the temperature does not rise until the ice has been melted.

In the neighbourhood of the poles, and on mountains of a certain height in all latitudes, there exist immense masses of permanent ice; and even in some districts of Siberia, where a kind of culture is practicable in summer, there are found, at a certain depth below the surface of the earth, strata of ice mingled with sand. In sinking a well at Yakutsk, the soil was found permanently frozen hard to the depth of 382 feet, and consisting in some parts entirely of ice. In the lower regions of the torrid zone there is no ice, and in the temperate zones it is a passing phenomenon. From

the polar ice-fields and glaciers which are always protruding themselves into the sea, great floating masses become detached and form *icebergs*, *flows*, and *drift ice* (see GLACIER). These bergs or mountains of ice rise some-

An Iceberg, showing the proportion under water.

times more than 250 feet above the sea-level. They present the appearance of dazzling white chalk cliffs of the most fantastic shapes. Fresh fractures have a green or blue colour. From the specific gravity, it is calculated that the volume of an ice-

berg below the water is about nine times that of the protruding part. Icebergs, and floes or ice-fields, are often laden with pieces of rock and masses of stones and detritus, which they have brought with them from the coasts where they were formed, and which they often transport to a great distance towards the equator. These floating masses of ice are dangerous to navigation. The *ice-foot* is the belt or fringe of ice along the shores in arctic regions.

The hardness and strength of ice increases with the degree of cold. In the severe winter of 1740 a house was built of the ice of the Neva at St Petersburg, 50 feet long, 16 wide, and 20 high, and the walls supported the roof, which was also of ice, without the least injury. Before it stood two ice-mortars and six ice-cannon, made on the turning-lathe, with carriages and wheels also of ice. The cannon were of the calibre of 6-pounders; the thickness of the ice was only four inches, and yet it resisted the explosion.

Faraday first called attention to a remarkable property of ice, since called Regelation. Two slabs of ice, with flat surfaces, placed in contact, unite into one mass even though the temperature of the surrounding air be considerably *above* the freezing-point. Faraday endeavoured to account for this by assuming that a small quantity of water, surrounded on every side by ice, has a natural tendency to become ice; and the fact that two blocks of ice placed in contact do not unite unless they are *most* seemed to bear out this idea. But J. Thomson gave a totally different explanation of this phenomenon. He showed that the capillary force in the film of water between the plates is sufficient to account for a very considerable pressure between them; so that from his point of view the phenomenon would be identical with the making of snow-balls by pressure, or with the formation, by a hydraulic press, of clear blocks from a mass of pounded ice, an observed fact, the explanation of which is to be found in the property of ice mentioned below. Faraday, taking up the question again, showed that the (so-called) regelation takes place in *water* as readily as in air, a fact quite inconsistent with the action of capillary forces. To this J. Thomson replied, showing, very ingeniously, that the capillary forces he at first assumed are not necessary to a complete explanation of the observed phenomena. See *Proceedings of the Royal Society*, 1860-61.

Other views of the question are numerous; for instance, that of Persoz, adopted by Forbes, in which ice was considered as essentially colder than water, and as passing through a sort of viscous state before liquefying, as metals do during the process of melting. This idea, however, has not of late found much support; and it is possible that the true solution of the question is, as J. Thomson pointed out, to be found in the analogy of the crystallisation of salts from their aqueous solutions.

However that may be, there is no doubt about the following property of ice, theoretically predicted by J. Thomson from the experimental fact of its expanding in the act of freezing, and demonstrated by means of the Piezometer by Sir W. Thomson—viz. that the freezing-point of water, or the melting-point of ice, is *lowered by pressure* to the extent of 0.0074 C. for every atmosphere of pressure; and the brothers have, with singular ingenuity, applied this to the explanation of the motion of glaciers. That a mass of glacier ice moves in its channel like a viscous fluid was first completely established by Forbes. Thomson's explanation of this motion is of the following nature: In the immense mass of the glacier (even if it were homogeneous, much more so when full of cracks and fissures, as it always is) there are portions subjected to a much greater

stress than others. The pressure to which they are subjected is such as corresponds to a melting-point considerably *below* the temperature of the mass, and therefore, at such points, if the ice be not altogether too cold it melts, the stress is relieved, and the whole mass is free for an instant to move nearly as a fluid would move in its place. But, the stresses being thus for an instant removed, the temperature and pressure of the water are again consistent with freezing—the thin layer of water quickly solidifies, and then matters proceed as before. Thus, at every instant, the stresses at different parts of the mass melt it at those places where they are greatest, and so produce the extraordinary phenomenon of a mass which might in common language be termed *solid*, and even *rigid*, slowly creeping down its rocky bed like a stream of tar or treacle. This explanation would not meet the case of extremely cold ice; and it appears that even extremely cold ice can be made to flow slowly; whence ice must have some true viscosity.

Ice trade and Manufacture. The trade in ice is now one of great and increasing importance. Ice has always been esteemed as a luxury in warm weather; and this early led to the storing of it in winter and preserving it for summer use. The Greeks, and afterwards the Romans, at first preserved snow, closely packed in deep underground cellars. Nero, at a later period, established ice-houses in Rome, similar to those in use in most European countries up to the present time. But these means were not enough to supply the luxurious Romans with ice for cooling beverages, and they actually established a trade in snow, which was brought to Rome from the summits of distant mountains. The trade in ice in Great Britain was, until a recent period, a very limited one, having been chiefly confined to the supply required by a few of the first-class fishmongers and confectioners—the private residences of the more opulent families being furnished with ice-houses (generally solid built cellars, wholly or partially underground), in which a sufficiency is kept for private use. But ice has come to be more and more largely used in preserving provisions, both in refrigerating chambers and otherwise. It is also used by brewers. In surgical operations ice is used to produce partial anaesthesia; it serves in fevers to cool the mouth and reduce the internal temperature, while ice in bags, applied to the spine, is found helpful in many cases of sea-sickness, and in other applications. Much ice is required in America, during the hot weather, for preserving dead bodies between death and burial.

Ice was imported into England from Norway on a considerable scale as early as 1823; but it was left to the Americans to originate a trade in this article in their own cities, which has extended to Europe and Asia, and in an incredibly short space of time attained a surprising magnitude. The export of ice from America was commenced about 1805, by a merchant named Tudor, who sent ice from Boston to the West Indies. After persevering against many losses he succeeded in establishing a trade with Calcutta, Madras, and Bombay; and now not only is it sent in vast quantities to those places, but also to Hong-kong, Whampoa, and Batavia. About the year 1840 the Wenham Lake Ice Company commenced sending ice to Great Britain from Boston. The supply of ice for Great Britain, however, now comes almost wholly from Norway (mainly from Drobak, near Christiania, where a lake was christened 'Wenham Lake,' after the Boston one; in 1888, 283,605 tons (value £178,482) were imported thence, and only 145 tons from all other countries. In 1896 the export from Norway to Britain had a value of £262,298. In severe winters the Norfolk Broads supply a quantity,

Thirty years previously America had sent to Great Britain on an average 20,000 tons annually, costing £20,000.

In America the ice harvest is gathered in on an enormous scale and with an elaborate system of apparatus. The ice is cleared from snow by means of an implement called the snow-plane. An ice-plough, drawn by horses, and driven by a man riding upon it, is then made to cut deep parallel grooves in the ice, and these are again crossed by other grooves at right angles, so that the whole of the surface is deeply marked out into small squares, measuring a little more than three feet. A few of these square blocks being detached by hand-saws, the remainder are easily broken off with crow-bars, and floated away to the ice-storerooms, which are usually built of wood, on the borders of the lake or river. Some of these are of vast dimensions, and contain vaults of great depth; the walls are double, sometimes treble, or even quadruple, being altogether as much as four feet in thickness, and having hollow spaces between to render them less heat-conducting. The blocks of ice are covered up with sawdust, a layer being placed between each tier of blocks. Many of these ice-houses are made large enough to hold from 40,000 to 80,000 tons of ice. The quantity of ice harvested in the United States may be guessed from the fact that Philadelphia requires an annual supply of 700,000 tons, New York and the adjoining cities, 1,200,000; while in some states the average consumption per head of the population is 1600 lb. yearly. New York is supplied from the Hudson; Philadelphia from the Schuylkill, Delaware, and Lehigh, as well as from the Kennebec; Boston from Wenham Lake, &c.; and the west from the great lakes. Throughout the States everywhere, except in the extreme north, the manufacture of artificial ice is now largely carried on—in 1890 by 222 factories with 3265 hands.

The building of ice-edifices is still a winter amusement in Russia; and, in the New World, Montreal set the example of an annual ice-carnival, one of the features of which is the building of a great ice-palace, and of ice-monuments of various kinds. Skating (q.v.) is the subject of a separate article. Ice-boating is an exhilarating recreation, pursued on frozen lakes and rivers, especially in America. The Canadian ice-boat or ice-yacht is not so much a boat as a triangular framework of wood, running by means of a sail with the broad end foremost—on three skates or runners, 3 feet long by 8 inches deep. There is but one large sail, usually triangular, fastened to a boom and yard, which may be over 30 feet in length. Such an ice-boat may be steered by the rudder-skate in almost any direction not in the teeth of the wind, and may attain an average speed of thirty or forty miles an hour, and sometimes as much as sixty-five miles. Snow seriously reduces the speed. For means devised for artificial freezing, see FREEZING MIXTURES, and GLACIER VEILS.

Ice Age. See GLACIAL PERIOD.

Iceberg. See ICE.

Iceland is an island in the North Atlantic immediately south of the Polar Circle, which just touches the northernmost point of the island, the Melakkasletta. It lies between 63° 23' and 66° 33' N. lat., and between 13° 22' and 24° 15' W. long. The meridian of Ferro crosses the island in the middle. The distance from Iceland to Greenland is about 250 miles, to Norway 600 miles, to the Faroe Islands about 250 miles, and to Scotland 500 miles. Its superficial area is 40,300 sq. m. (more than a third larger than Scotland); its length from east to west 300 miles, and its breadth from north to south 200 miles. The

whole length of the south coast from east to west is entirely wanting in bays and firths; the coast-line is not, however, straight, but bulges out largely in the middle, and the north coast has an inward corresponding curve. Other parts of the coast, especially the north-west and east coasts, are very much indented by firths and bays, as may be seen from the fact that the circumference of the island, if measured from point to point, is only 900 miles, but the coast line following the indentations would be above 2000 miles. The principal bays and firths of the island are Faxallói, Breiðfjörð (Broad Firth), and Isafjörð (Ice Firth), on the west coast; the Humallói (Bear cub's Bay), Skagafljörð (Ness Firth), Eyafjörð (Island Firth), and Skjalfandahlói (Shivering Bay), on the north coast. On the east coast there are no large firths, but many small ones; the best known of these is Seyðisfjörð (Fry Firth).

Taken as a whole, Iceland may be said to be a tableland about 2000 feet high. In some parts it slopes pretty evenly down to the coast, as is the case on the south side between Eyafjallajökull and Reykjanes. Here is the largest extent of lowland, about 1400 sq. m. The next largest piece of lowland is the Borgarfjörð, which extends to the Snaefellajökull range of hills, and is about 400 sq. m. The firths in the north-west, in the north, and in the east, may be looked upon as so many cuttings in the tableland effected by volcanic and glacial action during former geological periods of the island. In most cases these cuttings are comparatively narrow, and hills rise to about 2000 feet abruptly from the water, ending in steep precipices, which afford breeding-places to an immense number of sea fowl. This is especially the case in the north-west and the east. In the north, and in some parts of the east, there are several broad valleys running from the firths into the interior. Iceland is throughout volcanic, and, according to geologists, it owes its existence entirely to volcanic action. The interior and highest part of the island consists of volcanic tuff; the hills of the east and west consist for the most part of basalt. The whole of the interior is occupied by barren sands, lava tracts, and icefields. The largest of these lava tracts is Odathalraum, about 1200 sq. m. The largest icefield is that of Vatnajökull, about 3000 sq. m., and all the icefields together cover 5360 sq. m. At the south-east corner of Vatnajökull is the highest mountain in Iceland, called Orcafajökull; it is 6426 feet above the level of the sea, and its upper part is covered with everlasting snow or ice; and so are more or less all mountains above 4000 feet, as the snow line is usually at from 3000 to 4000 feet. There are twenty volcanoes which have been active at one time or another since the island was inhabited. The most famous of these is Hecla (q.v.), because its eruptions have been most frequent. There are, however, other volcanoes, such as Laki, near Skapta, which have been the seats of more gigantic eruptions. This volcano threw out in 1783 a lava stream about 45 miles in length and nearly 15 miles in breadth. Such an outpour from one volcano at one time is unexampled anywhere else. The south-west peninsula, Reykjanes, has frequently been disturbed by volcanic outbursts, which have not been confined to the land, but islands in the sea round it have been thrown up or submerged alternately by submarine volcanic action. As a result of this volcanic activity, 2400 sq. m. of Iceland are covered with lava. Many of the ice-hills have been active volcanoes during the last 600 years, such as Orcafajökull and Eyafjallajökull. These ice-volcanoes never throw out any lava, but mud and ashes. The numerous hot springs scattered about the island are also connected with the

volcanic fires; these are in many parts made use of by the inhabitants for cooking and washing purposes. There is great difference in the heat of these springs; some are just warm enough for bathing, others convert their water into steam at a degree far above the boiling point. The most famous of these hot springs is Geyser (q.v.). Earth quakes sometimes do a great deal of damage in various parts of the island, as in 1896.

Many considerable rivers run from the interior either north or south, but none of them are navigable, because of their rapidity. The longest are Thjórsa (Ball River) in the south, Jökulsá a Fjöllum and Skjálfandlufjót in the north, each being above 100 miles in length. Of the numerous lakes, Thingvallavatn in the south and Mývatn in the north are the largest. Of the many pretty waterfalls may be mentioned Gullfoss in Hvíta, Gothafoss in Skjálfandlufjót, and Dettifoss in Jökulsá.

Iceland is not rich in minerals, at least not in paying quantities. There are many sulphur-mines, and some of them have been worked till lately with English capital, but not with profit. Surtarbrandur (lignite) and brown coal are found in many places, as well as iron and lime, but it is very doubtful if it would pay to work them.

The climate of the south of Iceland is somewhat like that of the north of Scotland—i.e. rather wet and changeable, but colder. In the north of the island the climate is drier and colder still. Thunderstorms are rather rare, and usually occur in winter. The winter is mild considering the latitude, but spring and summer are frequently cold. The mean temperature of the years 1884-89 in the north was about 35° F. The greatest peculiarity of the Iceland climate is the varying mean temperature of the same month, the difference sometimes being 27°. This is owing to the arrival or non-arrival of the Greenland ice, which not infrequently blocks up the north and east coasts of the island from April to September.

The only cereal found in Iceland is the so-called mehur (*Elymus arvensis*), a kind of wild oats. Turnips, carrots, cabbages, and potatoes thrive very well, and are now cultivated to some extent. The grasses, both wild and cultivated, however, are the principal product of the island. Of trees there is the birch (*Betula intermedia*), seldom exceeding 12 feet in height, and some willows and juniper bushes; amongst the heather are found crowberries and whortleberries.

The only wild animals are the fox and the reindeer; there are both white and blue foxes. Reindeer were introduced in 1770, and there are still a few herds of them running wild on the hills in the interior; they are of very little use to the inhabitants. Of domestic animals the sheep is the most important; it is usually horned, sometimes even with three and four horns, and has some general resemblance to the black-faced sheep of Scotland. The lambs are weaned about the end of June, and the ewes are milked. Large numbers of them are now exported alive to Scotland and England. The cows are of a small breed, but yield a larger quantity of milk in proportion to their size than most other cows. The ponies are generally about 12 hands, but very strong and sure-footed. Thousands are brought to Scotland every year. The genuine Iceland dog has some resemblance to the Eskimo dog and the Scotch collie. According to the latest statistics there are about 20,000 cattle, 500,000 sheep, and 30,000 ponies in the island. Of birds there are immense numbers, especially of water fowl, the most important of which is the Eider duck (q.v.); it yields large quantities of eider-down, and is almost a domesticated bird in many parts of the island. The ptarmigan is the only game-bird. The most

remarkable bird of prey is the Icelandic falcon, formerly so much esteemed for falconry. Of other birds, the whooper or wild swan may be mentioned; it breeds largely in Iceland. The sea around the coasts is very rich in fish, especially cod and herring; the cod-fisheries have been carried on a long time by the islanders, and now also by the French, who employ annually between 200 and 300 vessels in this fishing. Little attention was paid to the herring-fishing till about 1880, when it was largely developed by the Norwegians, and now also by the Icelanders themselves. Finbacked whales, of late successfully fished by the Norwegians, and seals are also numerous. Many of the salmon and trout rivers are now rented by Englishmen. There are no snakes to be met with throughout the whole island—to cite the whole of the memorable seventy-second chapter repeated by Dr Johnson from Horrebow's *Natural History of Iceland* (Copenhagen, 1750; Eng. trans. 1758).

Iceland was discovered about the beginning of the 9th century by Irishmen or Scotsmen, but they did not make any permanent settlement. About seventy years later it was rediscovered and colonised by Norwegians, who preferred to leave their native land rather than submit to the rule of Harold Haarfager. Many of them had previously settled in the Orkneys, Hebrides, and Ireland; and when they were not safe there from the attacks of Harold, they went to Iceland, and a considerable number of Irishmen and Scotsmen went with them. Ingolf was the first settler. In about sixty years the whole island was inhabited, and an aristocratic republic was formed, the central point of which was the Althing which met every year at Thingvellir. In 1262-64 the Icelanders acknowledged the sovereignty of the king of Norway; and in 1388, when Norway was united with Denmark, Iceland shared the same fate. When, however, Denmark had to give up Norway in 1814, Iceland remained with Denmark, because, it is said, the negotiators of the peace of Vienna in 1814 did not know that there was such an island as Iceland in existence. The Althing continued under the Norwegian and Danish rule with very limited powers till 1800, when it was abolished. In 1874 the king of Denmark gave the island a new constitution, according to which the Althing, which had been reorganised in 1843, obtained legislative powers in all matters concerning Iceland. The king appoints a governor (Landshof-thingi), who, with a small council, carries on the government till 1893 under a secretary for Iceland in Copenhagen. In the year 1000 Christianity was introduced in Iceland, and a century later two bishops' sees, one at Skálholt, the other at Hólar, were established. About the middle of the 16th century the Reformation was introduced in Iceland, and since then all the Icelanders have remained Lutherans. Church matters are now superintended by one bishop at Reykjavik.

The most notable events in the history of Iceland from its union with Norway are a long series of afflictions and calamities, caused by volcanic outbursts, severe seasons, epidemics (such as the black death in 1402, the great plague in 1494, the ravages of the smallpox), and in some cases by misgovernment. The population of Iceland in 1804 was 46,240; in 1880, 72,422; in 1890, 70,927; in 1895, 73,149, though in 1872-95, 9000 emigrated to America. In the 12th and 13th centuries the Icelanders produced more vernacular literature than any other nation in Europe, and from that time love of information has been a distinguishing feature of the Icelanders. At the present day elementary education is so general that a child of ten unable to read is quite an exception, and most of them can write also. There are several schools for children, but for the most part

education is imparted at home. There are two higher schools for general education, and a college at Reykjavik for classical instruction; there are also two other colleges for ministers and medical students. Many farmers are acquainted with two foreign languages. Reykjavik, on the south-west coast, is the capital of Iceland, with about 3000 inhabitants. There are two other villages, Isafjord in the north-west and Akureyri in the north, each with 500 inhabitants. For the rest the population is scattered all round the island on isolated farms. The principal means of support of the Icelanders are the rearing of live-stock and fishing. The chief exports are: live sheep, in 1889 about 60,000; salt mutton, 600,000 lb. annually; wool, 1,200,000 lb.; sheepskins, 20,000; tallow, 60,000 lb.; horses, about 2000; salted cod, haddock, and ling, 14,800,000 lb.; salted salmon, about 40,000 lb.; cod-liver oil, about 1800 barrels; shark-liver oil, 4000 barrels; eider-down, 6400 lb.; and feathers, 12,000 lb. The annual imports are: corn and breadstuffs, 10,971,000 lb.; coffee, 440,000 lb.; ebony, 190,000 lb.; sugar, 1,025,000 lb.; salt, 46,000 barrels; tobacco, 133,000 lb.; spirits, 42,000 gallons; beer, 16,000 gallons; petroleum, 55,000 gallons; coal, 4500 tons; fishing lines and ropes, 55,000 lb. Besides these, timber, iron, cotton goods, and other clothing stuffs are imported. The value of the foreign trade, in 1849 only £168,000, was in 1895 £830,350. There are now import duties on spirits and wines, tobacco, coffee, and sugar. The trade with Iceland was confined to Copenhagen for several centuries, and so is the largest part of it still. Since the year 1854 the trade has been free to all nations, and now it is going more and more to Leith and Newcastle. The only native industry consists in working the wool of the sheep into various articles of clothing; this is chiefly done by the women in winter. The Icelanders make a sort of tweed which they call vatnadal, and this is the principal clothing material of the inhabitants, but is not exported. On most farms there is an old-fashioned loom in which the vatnadal is woven.

Forbes, *Iceland: its Volcanoes, Geology, and Glaciers* (1840); Sir Richard F. Burton, *Ultima Thule: a Summer in Iceland* (1875); J. C. Poestion, *Island das Land und seine Bewohner* (Vienna, 1885); and A. Baumgartner, *Island und die Fjoroe* (Freib. i. Br. 1889).

ICELANDIC LANGUAGE AND LITERATURE. The language which is now called *Icelandic* was down to the 13th century spoken all over Scandinavia, i.e. in Norway, Sweden, and Denmark, as well as in the Faroe Isles, Shetland, the Orkneys, the Hebrides, and on the coasts of England, Scotland, and Ireland. It was a sister language to the Anglo-Saxon and Old German. Formerly its name was *Dansk Tungu* (the Danish tongue) or *Norrœna* (the Northern tongue). Its similarity to Anglo-Saxon was so close that the ancient Icelandic authors asserted that the same language was spoken in England till the arrival of William the Conqueror as in Scandinavia. This is the language which the Norwegians brought over to Iceland in the 9th century, and because it is now nowhere spoken but in Iceland, it is called *Icelandic*. The present Danish and Swedish stand in the same relation to it as Italian and Spanish stand to Latin. In Iceland it has undergone so little change that any Icelandic child who has learned to read can read the sagas and songs of the 12th and 13th centuries as easily as an English child can read Shakespeare. There is, however, reason to believe that the pronunciation has been somewhat altered, especially that of the vowels and two of the consonants: the *E* and the *I* have in some words been

softened into *g* and *ð* (th) respectively. The vocabulary, the inflexions, and the grammatical construction have been preserved almost unaltered. The relationship to Anglo-Saxon and English may be seen at a glance, so many words in both languages being quite the same. We will take as instances several names of the body, as Icelandic *hand*, 'hand'; *finger*, 'finger'; *fole*, 'foe'; *bak*, 'back.' And if this is the case with English, it is still more so with Scotch, for generally, where the Scotch differs from the English in pronunciation of a word, it is identical with that of Icelandic. In some cases the consonant has been softened in English where it has remained hard in Icelandic: thus the letter *h* in connection with *s* is a softened form of *k*—e.g. 'shall' is in Icelandic, *shal*; 'shell' is *skel*; 'ship' is *skip*, and instances of this kind might be multiplied infinitely. The Icelandic is an inflectional language, having four cases not only for the nouns but also for each gender of the adjectives, some of the numerals, and the pronouns. With regard to the phonetics of the language, it may be remarked that vowel change (*vandaut*) has been carried further than in any other of the Teutonic tongues. The chief characteristics which distinguish Icelandic from German and English are the ending of the infinitive in a vowel, usually *a*, the suffixing of the definite article, and the passive or middle voice of the verb. To every student of Northern history the question must occur, why this ancient tongue has been preserved in Iceland, and not as well in some other parts of the north which have been quite as isolated as Iceland. We have no hesitation in giving as reason the fact that the Icelanders were the only people who had any literature in it, and always took great interest in that literature. This literature has not merely a philological interest, but even more historical interest, as it contains a full account of the men who left their mark in every corner of Europe, who were, in fact, masters of Europe during the 9th and 10th centuries, and whose language and laws are at this moment important elements of the language and institutions of the English-speaking race. It also throws no obscure light on the beliefs and modes of life of our common ancestors.

The earliest monuments of this tongue are found in the Runic inscriptions of Scandinavia (see RUNES). The remains thus found are indeed very different from the language as it appears in Icelandic literature; there is, however, sufficient similarity to show that the language there employed is really the same. The Runic monuments range from the 8th to the 12th century. The earliest literary productions in the Icelandic tongue are the mythical songs contained in the so-called poetical Edda (q.v.), the collection of which has, we believe erroneously, been attributed to Saemund the Learned, who died in 1133. It is impossible to ascertain how far these songs were brought to Iceland by the Norwegians, though some of them seem to point to a time anterior to the settlement of the island. The only thing we know for certain is, that they existed in Iceland in the later part of the 12th century. The identification of some or all of them with either Norway or the Western Islands is founded on no firmer basis than mere conjecture. These songs may be divided into mythical and heroic songs. The mythical songs contain an account of the gods and giants, the creation of the world and of man, the world-long struggle of the gods with the giants or Titans of the Northern mythology, the day of judgment, or the destruction of the gods, the giants, and the world, out of the ruins of which a new heaven and a new earth are to arise. One of the songs of this collection is the *Havamal* (the Song of the High One, viz. Odin); it is a didactic

poem containing rules of conduct in various situations and views of life. The heroic songs mostly treat of the same subject as the German *Nibelungenlied*. Some of these songs contain the most exquisite expressions of Icelandic poetry. There are several other songs of the same type as the Edda. All these songs are alliterative; their characteristics are simplicity of diction and natural expression. By the side of these popular songs a more artificial poetry was developed by the Skalds (q.v.); here rhyme was added to alliteration, and the expression was so artificial that they could be understood by the initiated only. As the theme of their poems was usually a king or chief, whose heroic deeds they celebrated in their songs, this kind of poetry has been called court poetry. Many of these songs formed the nucleus of the later saga. Either the Skald himself, or another person who had learned his poem, would recite it, give explanations of it, and add further particulars to the life of him whom the poet celebrated, and thus the saga took shape shortly after the celebration of the events in the song. Thus a literature arose without the use of letters.

The runes were used only for inscriptions, not for literary purposes. Some authorities, however, are of opinion that the earliest Icelandic writings were in runes, but, as there is not a single title of such writing left as evidence, the conjecture seems very hazardous. The first Icelandic bishop, Isleif, who died in 1080, introduced the Latin alphabet, and taught young men in preparation for the priestly office. In the beginning of the 12th century another bishop had a school where Latin was taught. Shortly afterwards began that literary activity which made the Icelanders famous. The old prose literature of Iceland consists for the most part of sagas—i.e. tales, both historical and fabulous. They are all more or less in the form of biographies; their authors are for the most part unknown. With regard to the scenes of the sagas, they may be divided into Icelandic sagas, or biographies of Icelanders in Iceland, the sagas of the kings of Norway, and sagas concerning other countries. These sagas give a faithful picture of the life and manners of those times, but chronology is usually their weakest point. The father of Icelandic literature was Ari the Learned (1067-1148). He was the first who began to write down the sagas, most of which had already been formed in the mouth of the saga-teller. The principal works of Ari are the *Landnámabók*, or account of the settlement of Iceland, containing the names, genealogy, and brief accounts of every settler. It is an evidence of very careful research and wonderful memory of the author. No other country in the world has such an account of its earliest history. He also wrote a small book called *Líflingur Íslandanna*, on the history of Iceland down to 1135, and an account of the introduction of Christianity called *Kristni Saga*. All these have come down to us; but he also wrote a larger book on Iceland which is lost, and the lives of the earliest kings of Norway, which are also lost except so far as they may be embodied by Snorra Sturluson (1178-1241), the historian and poet. His best-known works are the prose Edda, or manual of Scandinavian mythology and Icelandic poetry, and the Lives of the Kings of Norway, or *Heimskringla*, down to the death of Sigurd the Crusader (1130). The third name is that of Sturluson's nephew, Sturla Thordarson (1214-84), also a poet and historian. He wrote the *Íslandlinga Saga*, also called *Sturlunga*, a graphic account of the feuds between the chiefs of Iceland in the 13th century, which resulted in the subjection of the island to the king of Norway. He also wrote the life of Hákon the Old, who died at Kirkwall in 1263, and that of his son Magnus. The latter is

now lost except a few fragments. The sagas already translated into English are: *Heimskringla*, *Orkneyinga Saga*, the story of Birni Njal, the story of Gísli the Outlaw, the *Fagafélms Saga*, the *Gunnlaugs Saga*, the *Volsunga Saga*, and several smaller ones.

Besides the sagas and poetry there are also found grammatical essays from the 12th and 13th centuries, astronomical treatises, a guide for travellers to Rome and Jerusalem. A remarkable work appeared in the 13th century called *Konungs Skuggsjá* ('king's mirror'), which contains a philosophical contemplation of life, with rules for conduct under various circumstances and in the company of all sorts of people. The old Icelanders were no less industrious translators than original writers, for they seem to have translated any foreign book that came into their hands. Thus they translated many medieval romances, such as the legends of King Arthur, and these translations are now of great value for the textual criticism of the originals. Among the most remarkable translations of those times is a version of the Old Testament, intermingled with various observations on natural history, compiled from medieval sources. This is perhaps the oldest translation of the Bible in any living language. There are also translations of a great number of homilies, of lives of saints, and legends of the church. The code of laws of the Icelandic republic, called *Grágás* (gray goose), first written down in 1118, affords ample evidence of great skill in legislative enactments, and is well worth studying in connection with the legal history of other Teutonic nations.

Shortly after 1300 the literary productiveness of the Icelanders ceased, except for the writing of annals, which had begun in the preceding century. The principal literary activity of the 14th century consisted in copying and making collections of the labours of former centuries. Many of the sagas have been preserved in these copies only, the originals being lost. The 15th century is almost a blank as far as literary activity is concerned, if we except a few song-writers; yet even then there were some students of the old sagas. About the middle of the 16th century a new turn was given to the literary pursuits of the Icelanders by the introduction of the Reformation. The whole Bible was translated and published in 1584, and many other theological works from Danish and German. In the 17th century the interest in the old literature was reawakened, and many parchments were transcribed. At this time also the collecting of manuscripts began, and they were carried partly to Sweden and partly to Denmark. To the latter country they were taken by the indefatigable collector Arni Magnússon, who died in 1730, after having bequeathed his collections to the university of Copenhagen. There is no doubt that this exportation of the manuscripts was very fortunate for their preservation. From this time the literary treasures of Iceland began to be known abroad; the first to make known the historical value of the sagas was the Icelandic Torfaeus, who died in 1719. Since then there has been no want of diligent and careful students of Icelandic literature both among Icelanders, Scandinavians, Germans, and lately also among the English.

The literary activity of the modern Icelanders is not confined to the study of the old literature alone; there is also a considerable modern literature, though it is comparatively less interesting. Iceland has always been and still is rich in song-writers, especially of a lyrical and religious tendency. To the natural history and the history of the island itself there have been valuable contributions. Considering the population and other circumstances of the island, it cannot be denied

that the Icelanders at the present day compare favourably in respect to literary activity with any other people in similar circumstances.

The best guide to the old literature of Iceland is to be found in the *Fæderdomina* to the *Sturlunga Saga*, edited by Dr G. Vigfusson (Oxford, 1878). See also the *Corpus Poeticum Boreale*, the poetry of the Old-Northern tongue to the 13th century (2 vols. 1885), edited, translated, and illustrated by Vigfusson and Powell. Cleasby and Vigfusson's great Icelandic-English dictionary (1874) is the standard one. There is a list of *Books printed in Iceland*, by Fiske (1890).

Iceland Moss (*Cetraria islandica*), a lichen found in all the northern parts of the world, and valuable on account of its nutritious and medicinal properties. It is collected as an article of commerce in Norway and Iceland. In very northern regions it grows even near the level of the sea; in more southern countries it is found on mountains. It is not uncommon in the mountainous parts of Britain, although not turned to any economic account. In Carniola it is used for fattening cattle and pigs. It grows in extreme abundance in Iceland on tracts otherwise desert; and numerous parties migrate from great distances with horses, tents, and provisions, in the summer months, for the sole purpose of gathering it as an article of commerce and for food. In many places this lichen thickly covers the whole surface of the ground, growing about 1½-4 inches high, and consists of an almost erect Thallus (q.v.). It is of a leathery and somewhat cartilaginous substance. When Iceland moss is used as an article of food its bitterness is first partially removed by steeping in water, after which, in Iceland and other

Iceland Moss (*Cetraria islandica*).

northern countries, it is sometimes pounded and made into bread; or it is prepared by boiling, the first water being rejected. It is often boiled with milk, making a kind of jelly, either with milk or water. It is an agreeable article of food, and very suitable for invalids. It contains about 80 per cent. of a kind of starch called *Lichen Starch*, or *Lichulin*, and owes its bitterness to an acid principle, *Cetrarinic Acid*.—An allied species, *Cetraria nivalis*, growing in northern countries, possesses similar properties.

Iceland Spar, transparent calc spar, or calcite, CaCO_3 ; it may be split along its cleavage planes into an obtuse rhombohedron, and is doubly refracting. See CALCITE.

Iceni. See BOADICEA.

Ice Plant (*Mesembryanthemum crystallinum*), an annual herbaceous plant, a native of Africa and of the south of Europe, remarkable for the watery vesicles (*papulae*) with which its whole surface is covered, and which have the appearance of granules of ice, and sparkle in the same manner in the sun. It is common as a tender annual in our greenhouses, and grows in the open garden during summer; the leaves are used for garnishing dishes. The expressed juice of the plant has been greatly extolled as a remedy for diseases of the mucous membrane of the lungs and urinary passages, and also for dropsy. The seeds are used for food in the Madeira Islands. The ashes supply barilla, and the plant is burned on this account

in countries where it abounds. The plant is valuable for extracting soda, potash, and other alkaline salts from unproductive soils, rendering them fit for culture. It is so used in the south of France.

Ichang, a walled town in the Chinese province of Hu-peï, stands on the Yang-tse-kiang, where it escapes from the limestone gorges and ravines of its middle course, and 1000 miles from Shanghai at its mouth. In 1877 it was declared open to foreign trade, but in consequence of the difficulties connected with the navigation of the river, the competition of the Chinese, and the jealousy of the Chinese officials it advanced but slowly. Nevertheless, the net value of the trade notified to the foreign customs-office increased from £21,304 in 1878 to nearly £2,300,000. The imports are chiefly shirtings, lastings, cloth, and silver in ingots, and the exports silk, white wax, drugs, musk, tin, and silver in ingots. The imports from Great Britain constitute about half of the total imports. Ichang is connected with Hankow by telegraph, and so with the outer world. Pop. 35,000. See Little, *Through the Yang-tse Gorges* (1888).

Ich Dien ('I serve'), the motto of Edward the Black Prince, whose badge was a single ostrich feather, afterwards three ostrich feathers. The story that he adopted both motto and badge from John, the blind king of Bohemia, after the battle of Crecy, is not borne out by historical investigation. Since Edward's time the motto 'Ich Dien' and the badge of three ostrich feathers have been employed as the cognisance of the Princes of Wales. See *Diet. Nat. Biog.*, vol. xvii. p. 92.

Ichneumon (*Herpestes*), a genus of digitigrade carnivorous quadrupeds of the family Viverridae, having a much elongated body, small head, sharp muzzle, rounded ears, and short legs. The species, which are pretty numerous, are natives of Africa and the warmer parts of Asia. One, the Andalusian Ichneumon (*I. ichneumon*, var. *Widdringtonii*), occurs in the south of Spain. They feed on small quadrupeds, reptiles, eggs, and insects.

Egyptian Ichneumon (*Herpestes ichneumon*).

Some of them, particularly the Egyptian Ichneumon (*I. ichneumon*) and the Mangouste, Mongoose, or Mongoose (*I. griseus*) of India, have been greatly celebrated as destroyers of serpents and other noxious reptiles, many wonderful fables being superadded to the truth on this subject. The Egyptian Ichneumon, the Ichneumon of the ancients, is larger than a cat, gray, with black paws and muzzle. It was a sacred animal among the ancient Egyptians. The Ichneumon is easily domesticated, and is useful in keeping houses free of rats and other vermin. It is therefore not unfrequently domesticated in Egypt, as the mongoose also is in India. This species is rather smaller, of a lighter colour, and has a pointed tail. Introduced into Jamaica, the mongoose did admirable service in clearing the sugar-cane fields of rats; but became

a plague by destroying poultry and harmless animals.

Ichneumon, a name applied to the members of a very large family of insects (Ichneumonidae), included in the order Hymenoptera, and notable because the larvae are parasitic in, or sometimes on, other insects. There are several thousand species, represented in all parts of the world, including many minute forms and also some of the largest insects. The long antennae have many joints; the abdomen is usually joined to the thorax by a narrow waist; the females are provided with ovipositors, which are in some cases very prominent. With these they lay their eggs in the ova, larvae, or adults of other insects, and sometimes also of spiders. The ichneumon embryos develop in the safe and comfortable hiding-place thus afforded, and utilise their hosts as food for a while, but sooner or later, before or oftener after pupation, leave them dead or dying. Sometimes, curiously enough, the ichneumon themselves fall victims to a similar trick played upon them by members of the same or nearly related families. As adults, these insects feed on the juices of flowers. The parasitic habit of the larvae is sometimes of economic importance, since they thus destroy injurious insects. Thus, *Microgaster glomeratus* and *Pimpla castigator* are parasitic on the caterpillars of the cabbage butterfly, and *Aphidius* upon aphides.

Ichthyology (Gr., 'science of footprints'). See FOSSILES.

Ichor, the ethereal fluid that supplied the place of blood in the veins of the gods of Greek mythology. The name is applied in medicine to the thin watery discharge from a wound.

Ichthyodorulite (Gr., 'fish-spear-stone'), the name given to fossil fish spines, not uncommon in the stratified rocks.

Ichthyology (Gr., *ichthys*, 'a fish,' *logos*, 'a discourse'), that branch of natural history which treats of Fishes (q.v.).

Ichthyornis. See ODONTORNITHES.

Ichthyosaurus (Gr., 'fish-reptile'), a remarkable genus of reptiles which inhabited the sea during the deposition of the Mesozoic strata. Like the modern Cetacea, their structure was modified to suit their aquatic life. The body was shaped like that of a fish, the limbs were developed into paddles, and the tail, long and lizard like, was furnished, it is believed, with a fleshy fin, as in the dolphin, except that its position was vertical. The head was large, and produced into a long and pointed snout, resembling that of the crocodile, except that the orbit was much larger, and had the nostril placed close to it, as in the whale, and not near the end of the snout. The jaws were furnished with a large series of powerful conical teeth, lodged close together in a continuous groove, in which the divisions for sockets, which exist in the crocodile, were indicated by the vertical ridges on the maxillary bone. The teeth were hollow at the root, sheathing the

Ichthyosaurus.

young teeth, which gradually absorbed the base of the older ones, and, as they grew, pressed them forward, until they finally displaced them. The long and slender jaws were strengthened to resist any sudden shock by being formed of many thin bony plates, which produced light and elastic as well as strong jaws. The most remarkable feature in the head was the eye, which was not only very large—in some specimens measuring 13 inches in diameter—but was specially fitted to accommodate itself for vision in air or water, as well as for speedily altering the focal distance while pursuing its prey. The structure, which thus fitted the eye so remarkably to the wants of the animal, consists of a circle of thirteen or more overlapping sclerotic bony plates surrounding the pupil, as in birds. This circle acted as a sort of self-adjusting telescope, and, assisted by the extraordinary amount of light admitted by the large pupil, enabled the ichthyosaurus to discover its prey at great or little distances in the obscurity of the night, and in the depths of the sea. The neck was so short that the body was probably not in the least constricted behind the head. The backbone was fish-like; each joint had both its surfaces hollow, making the whole column very flexible. The small size of the paddles compared with the body, and the stiffness of the short neck, seem to suggest that the tail must have been an important organ of motion. Professor Owen is satisfied that it was furnished with a vertical tail, because the vertebrae are compressed vertically, and also because the tail is frequently found disarticulated a short distance from its extremity, as if the weight of the upright tail

had caused it to fall when the animal had begun to decompose. The fish-like body, the four paddles, and especially the powerful tail would make the ichthyosauri active in their movements, and consequently, with their predaceous habits, very dangerous enemies to the other animals that inhabited with them the Mesozoic seas. That their principal food consisted of fishes is evident from the masses of broken bones and scales of contemporary fishes that have been found under their ribs in the place where the stomach of the animal was situated. Not infrequently entire skeletons of small individuals have been found within the thoracic and abdominal cavity of larger ones. As these small skeletons are complete and uninjured and of the same species as that in which they occur, Professor Seeley thinks that some of the ichthyosauri were viviparous.

The remains of ichthyosauri are peculiar to the Mesozoic strata, occurring in the various members of the series from the Lower Lias to the Chalk, but having their greatest development in the Lias and Oolite. More than thirty species have been discovered; they differ from each other chiefly in the form of the head, some having a long and slender snout, like the gaviel of the Ganges, while others had short and broad heads, more like the common crocodile. The great repository for ichthyosaurial remains hitherto has been the Lias at Lyme Regis.

Ichthyosis, or FISH-SKIN DISEASE, is characterised by a hardened, thickened, rough, and almost horny state of the cuticle in severe cases. Instead of exfoliating in fine, almost invisible flakes, it accumulates in irregular scale-like pieces.

which may be removed, but are speedily reproduced. Perspiration is always absent or very deficient in the affected areas. The disease may affect almost the whole surface, or may be confined to a single part; and is most frequently, but not always, congenital. It is attended by no constitutional disturbance, and the general health is often very good. The disease is, however, extremely obstinate, and when congenital may be considered as incurable. Treatment consists in the frequent use of warm or vapour or alkaline baths, so as to soften the thickened epidermis and to facilitate its removal, and friction by means of a piece of flannel or pumice-stone may be conjoined with the bath. The application of sulphur or resorcin to the skin has also the effect of promoting desquamation. The employment of sulphureous baths, such as those at Harrogate, has occasionally been found of temporary use; and the internal administration of tar, cod-liver oil, &c. sometimes gives relief.

Icknield Street (Lat. *Via Ikeniana*), an ancient Roman road of Britain, which ran from Norfolk south-westwards to the vicinity of Land's End.

Icolmkill. See IONA.

Icon Basilike. See ETKON.

Iconium, an ancient town of Asia Minor, situated on the western edge of the plateau that skirts the northern slopes of the Taurus Mountains, 310 miles E. of Smyrna. The capital under the Romans of Lycaonia, it was three times visited by St Paul, who founded there a Christian church. In 708 it fell into the hands of the Arab conquerors. Its prosperity culminated in the end of the 11th century, when it was made the capital of the Seljuk empire. In 1190 Frederick Barbarossa defeated the Turks in the neighbourhood, and captured Iconium. Some fifty years later its sultans were made the political playthings of the Mongols; and in 1392 they submitted to the suzerainty of the Ottoman Turks, though the state was not incorporated in the Ottoman empire until 1486. Being the meeting-point of some of the principal highways of Asia Minor, and a place of considerable trade, it failed not to figure prominently in the wars of the Turks. In 1832 Ibrahim Pasha defeated the Turks there.—The modern town, called KONIEH or KONIYA, the capital of the Turkish vilayet of Konieh, is a place of 20,000 or 30,000 inhabitants, who live by commerce, by making stockings and gloves, and on the contributions of the numerous pilgrims who visit the sacred tombs and other holy places of the town. Here is the principal monastery of the Mevlevi or 'dancing' dervishes in the Ottoman empire. Numerous ruins of mosques, madrasas (colleges), &c. attest the decayed splendour of the place.

Iconoclasts (Gr. *eikon*, 'an image,' and *klazō*, 'I break'), the name used to designate those in the church, from the 8th century downwards, who have been opposed to the use of sacred images (i.e. of statues, pictures, and other sensible representations of sacred objects), or at least to the paying of religious honour or reverence to such representations. The iconoclast movement had its commencement in the Eastern Church. Opinion is divided as to the origin and antiquity of the practice of image-worship (q.v.) in the church; but it is certain that in the 6th or 7th century it prevailed extensively, especially in the eastern empire, and that practices existed in some churches which were a source of much suspicion, and even of positive offence. Many bishops interposed to correct these abuses; but the iconoclast movement, strictly so called, began with the imperial edict issued in 726 by the Emperor Leo III., surnamed the Isaurian, forbidding the honours paid to sacred images, and

even commanding the removal from the churches of all images, that of our Lord alone excepted. This was followed by another decree in 730, which prohibited, under pain of death, as sinful and idolatrous, all acts of reverence, public or private, to images, and directed that wherever such images should be found they should forthwith be removed or destroyed. The attempt to enforce this decree aroused great opposition, especially in the Greek islands and in Italy. The popes Gregory II. and Gregory III. protested vehemently against it, repudiated the imputation of idolatry, and explained the nature of the honours to images for which they contended. Leo persevered, nevertheless, in his opposition, which was continued by his successor, Constantine, surnamed Copronymus. Under this emperor a council was held in Constantinople in 754, in which the iconoclast decrees were affirmed in their fullest extent; and Constantine's son, Leo IV., renewed, on his accession in 775, the enactments of his predecessors. Under the widow of Leo, the Empress Irene, a council was held at Nicea (787), in which these proceedings were condemned and revoked; but other succeeding emperors, Nicephorus (802-811), Leo V., the Armenian (813-820), Michael II., the Stammerer (820-829), and Theophilus (829-842), returned, with greater or less severity, to the policy of the iconoclast emperors. As regards the Greek Church the controversy may be said to have been finally settled under the Empress Theodora in a council held at Constantinople in 840, or at least by a subsequent one of 870. The modern usage of the Greek Church permits pictures, but rejects gilded or sculptured representations of sacred objects. Except in Italy, the iconoclast controversy created but little sensation in the Western Church until the movement in the time of Charlemagne and his successors, to be noticed under the head IMAGE-WORSHIP.

Iklinus. Of Ictinus, who shares with Callicrates the glory of having designed the one perfect building which the world has ever seen, very little can be stated with certainty. In addition to his masterpiece, the Parthenon, the temple of Apollo Epicurius at Bassæ, near Phigalia, the sculptured reliefs from which are now in the British Museum, may be ascribed to him. He is also known to have been the architect of a temple at Eleusis, and to have written an exhaustive treatise upon the Parthenon, with which his name is indissolubly connected. See ATHENS.

Ida, a mountain-range in Asia Minor, extending from Phrygia through Mysia into the Troad. The city of Troy was situated at its base. It is the scene of many ancient Greek legends. The southern part of the range was called Gargarus, the highest peak of which is 5749 feet above the sea. Here there was a temple of Cybele, who therefore was called the *Idæan Mother*. From Ida flow several famous streams, as the Granicus, Simois, and Scamander. There is another Ida (8055 feet) in Crete, extending from west to east, now called Psiloriti. Here Zeus was said to have been educated.

Idaho, since 1890 one of the United States, is situated between the 42d and 49th parallels of latitude, and mainly between the copyright 1900 by J. B. Lippincott 111th and 114th meridians of Company. longitude. In shape it is an irregular trapezoid. Its maximum length is about 490 statute miles; its breadth varies from about 12 miles at the 'pan-handle' which forms the northern part, to 300 miles along the southern boundary. Its area is about 84,800 sq. m.

One of the main ranges of the Rocky Mountains, in various parts called the Cabinet, Cœur d'Alene,

and Bitter Root mountains, forms the north-eastern boundary, separating Idaho from Montana. In the southern part this range is a portion of the continental divide between the Atlantic and Pacific oceans. About 70,000 sq. m. of the territory is situated in the drainage basin of the Columbia River; the remaining part lies in the Great Basin, its surface waters flowing into Great Salt Lake.

A comparatively small area in the south excepted, the entire surface is rugged and mountainous. In addition to the high range on the north-eastern border spurs of this range traverse the territory in a direction generally east and west. Of these Salmon River Mountains are perhaps the most noteworthy, as they separate what is popularly known as Northern Idaho from the plateau region in the central and southern part. All these ranges are high, their summits reaching elevations of 10,000 feet and upwards. The average altitude of the territory is about 5000 feet. The lowest level is the valley of Snake River, which at Boise City is 2000 feet above the sea-level. In the south are a number of irregular ridges largely shaped by erosion, locally known as the Bear River Mountains, Goose Creek Mountains, South Mountains, Black-foot Range, &c. A part of the plateau-region is included in the great lava flood which occurred in comparatively recent geological times, and which is still noticeable in the cliffs and mesas that diversify the surface.

Snake River—also known as Shoshone, and as Lewis River—drains by far the largest part of the territory. Its course (about 850 miles in length) lies in a valley remarkable for scenic beauty. In various places the valley widens out into broad savannas susceptible of a high degree of cultivation. The open valleys alternate with narrow cañons through which the river flows in dalles and cataracts. This river is navigable from the mouth of Powder River to Salmon Falls, a distance of 200 miles. Salmon River, one of the largest tributaries of Snake River, drains the central part. The character of its valley is much like that of the latter. Clearwater, Payette, Boise, Weiser, Buneau, Malade, and Goose rivers are tributaries, important mainly for the fertile lands which flank their courses. Pend d'Oreille, or Clarke's Fork, drains Northern Idaho. Its main tributaries are Coeur d'Alene and St. Joseph rivers. Dalles, cascades, and cataracts characterise all the rivers of the territory. Shoshone Falls almost rival those of Niagara in grandeur.

There are two lake-regions; one in the panhandle, the other in the south-east. The former includes Pend d'Oreille, Coeur d'Alene and Kamiks lakes; the latter, John Day and Bear lakes. The surplus waters of Bear Lake flow through Bear River into Great Salt Lake. These lake-regions abound in game, and are perhaps the finest hunting-grounds in the United States.

Among the wild animals are the grizzly bear, two species of brown bear, the black bear, raccoon, panther, badger, wolf, fox, and coyote. Fur-bearing animals are represented by the lynx, mink, and beaver. The bison, once common, is now rarely if ever seen. The moose and elk are occasionally met with. Deer of two species and antelope are numerous. The Rocky Mountain sheep is found in the Coeur d'Alene Mountains.

Vegetation is abundant in the northern and central parts, but somewhat deficient in the arid lands of the south. Forests of conifers, including white, yellow, black or lodge pole, and sugar pine, as well as several species of cedar and spruce, cover the western slopes of the Bitter Root and Coeur d'Alene mountains. These forests embrace a wealth of timber not surpassed by any other equal area on the continent. Fir, tamarack, and larch

are also abundant. In the central and southern part the forests give place to extensive mesas overgrown with sage brush, and rolling lands covered with bunch grass. The river valleys are dotted with occasional groves of cottonwood and thickets of wild fruits, such as the blackberry, wild currant, salal, and fox grapes.

The mineral wealth of the state consists chiefly in its mines of silver, lead, gold, and copper, productive in the order named. The output of these metals has sometimes reached nearly \$20,000,000 in a year. Coal of good quality has been discovered in seven of the eighteen counties. In the basin region of the south-east soda, gypsum, sulphur, and minerals common to lacustrine deposits abound. Mineral springs are numerous.

The climate is exceedingly healthy. The extremes of temperature rarely range beyond 0° and 90° F., except in regions of great altitude. The rainfall, abundant in the north, is deficient in the south, so that irrigation is necessary to ensure full crops. The agricultural products, stock and farm, aggregate well over \$10,000,000. Grain farming is of necessity confined to the narrow river-valleys, and, as a whole, the territory is better adapted to stock-raising than to cultivation. The crops are largely moved by wagon-trains and river-boats, but there were in 1890 about 1000 miles of railway.

Idaho, constituted a territory in 1863, received its present limits in 1865, and in 1890 was raised to the rank of state. Gold was first found in 1852, and raised in paying quantities in 1860. The population, distributed mainly along the river-valleys of the south and west, was returned at 14,999 in 1870, and 32,610 in 1880; in 1890 it was 84,385, about one-fifth consisting of people of the Mormon faith. There are also upwards of 10,000 Indians not included in the foregoing numbers. The public schools and religious and charitable institutions are well supported.

Boise City, the capital and largest city, had in 1890 a population of 2311. Montpelier and Weiser came next in size.

Iddesleigh, EARL OF, Conservative statesman, better known as Sir Stafford Northcote, was born of a very old Devonshire family, on 27th October 1818, and was educated at Eton and Balliol College, Oxford, gaining a first-class in classics. He began public life in 1842 as private secretary to Mr Gladstone, who was then President of the Board of Trade. In 1847 he was called to the bar, and four years later succeeded his grandfather as eighth baronet. He was secretary to the commissioners of the Great Exhibition, and for his services was created a C.B. In 1855 he entered parliament as Conservative member for Dudley, and in 1858 was elected for Stamford, in 1866 for North Devon. He sat for the latter constituency until 1885. He was Financial Secretary to the Treasury in Lord Derby's ministry of 1859, and in 1866 he was appointed by the same prime-minister President of the Board of Trade. He had already demonstrated his knowledge of finance by his treatise entitled *Twenty Years of Financial Policy*, published in 1862. While at the India Office in 1868 Sir Stafford Northcote was charged with the responsibility of the Abyssinian Expedition, which under his auspices was carried to a successful issue. In 1871 his old ally Mr Gladstone appointed him British Commissioner to the United States for the adjustment of the Alabama difficulty. Sir Stafford Northcote was Chancellor of the Exchequer in Mr Disraeli's ministry of 1874, and among other useful measures which he introduced, in addition to his budgets, was the Friendly Societies Bill of 1875. In the debates on eastern affairs and the Suez Canal he rendered signal service to the government. When Mr Disraeli went to the Upper House Sir Stafford

succeeded to the leadership in the Commons, and his task was very arduous in connection with the Irish debates. Upon the death of Lord Beaconsfield he became joint leader of the Conservative party with the Marquis of Salisbury. His management of the Tories in the Lower House during several years of opposition elicited warm eulogiums. When Lord Salisbury came into power in 1885 Sir Stafford Northcote was raised to the peerage, under the title of Earl of Iddesleigh and Viscount St Cyres, and was appointed First Lord of the Treasury. He sat as chairman of the committee appointed to inquire into the depression of trade. In 1886 he was the recipient of a handsome testimonial, subscribed by members of both political parties. In Lord Salisbury's second ministry Lord Iddesleigh was Foreign Secretary; but he resigned this post early in January 1887. On the 12th of the same month he died very suddenly at the premier's official residence in Downing Street. Lord Iddesleigh was elected Lord Rector of Edinburgh University in 1883, and during his tenure of office delivered an excellent address to the students on 'Desultory Reading.' See his collected *Lectures and Essays* (1887), and the Life by Andrew Lang (1890).

Idea. This word has borne very distinct meanings in the history of philosophy. Down to the 17th century it had the signification given to it by Plato, and referred to the Platonic doctrine of eternal forms existing in the Divine mind, according to which the world and all sensible things were framed. The word was used in this sense in literature as well as in philosophy down to the 17th century, as in Spenser, Shakespeare, Hooker, and Milton.

In speaking of the mental representation of external things, Descartes, instead of employing the various terms *image*, *species*, *phantasm*, &c., which had been the words formerly in use for that particular signification, used the word *idea*. In this he was followed by other philosophers, as, for example, Locke, who states that he has adopted the word to stand for 'whatever is the object of the understanding, when a man thinks.' Thus, the mental impression that we are supposed to have when thinking of the sun without seeing the actual object is called our *idea* of the sun. The *idea* is thus in contrast with the sensation, or the feeling that we have when the senses are engaged directly or immediately upon the thing itself. But the word has been very variously used, as by Berkeley, Hume, Kant, Hegel (see these articles). For innate ideas, see COMMON SENSE, LOCKE.—*Idealism* is a term used almost as variously as *Idea*. Idealism may be a theory concerning our knowledge of external existence, restricting mind directly to knowledge of its own state, whereas the opposed *realism* implies a direct knowledge of the external. Idealism may be also a theory as to the nature of the universe, and be spoken of (rightly or wrongly) as *subjective* idealism, as in Fichte (q.v.), *critical* as in Kant (q.v.), or *absolute* as in Hegel (q.v.). See also BERKELEY. In the mediæval controversies between nominalism and realism, realism was a kind of idealism (see NOMINALISM). Idealism is also used for ethical and æsthetic systems which adopt an ideal standard of estimating character, human possibilities, or subjects in art (see REALISM). The word realism has a further peculiar sense in Herbart (q.v.).

Ideler, CHRISTIAN LEOPOLD, astronomer and chronologist, was born 21st September 1766, near Pehleberg, in Prussia, and, after holding various offices, received a professorship at the university of Berlin in 1821. He wrote several valuable works on chronology, and died August 10, 1846.

Ides. See CALEND.

Idiocy is defined by Ireland as 'mental deficiency or extreme stupidity depending upon malnutrition or disease of the brain occurring either before birth or before the evolution of the mental faculties in childhood; while Imbecility is generally used to denote a less decided degree of such mental incapacity.' The difference between both conditions and *dementia* (see INSANITY) is that the dement was once sane and responsible, the idiot and the imbecile never developed mental capacity at all; they remained arrested children. The name *amentia* has been given to idiocy. The mental faculties never showed themselves in any high degree, because the organ of mind in the brain never developed. There are great varieties of idiocy and imbecility. Some of the lowest have no speech, no power of distinguishing between one person and another, no affection or hatred, no feelings of pleasure or pain, no power to take care of themselves, and can never be taught any of these things. In body such idiots are dwarfish, misshapen, ugly, with the features and expression of face often of the lowest of the lower animals, with no power of walking. This being the condition of the lowest varieties, they rise gradually in the scale till many imbeciles are beautiful in features, and reach normal bodily development, but are slightly wanting in some essential mental faculty, in intelligence, or in affection, or control, or self-guidance. The mental deficiency is in by far the majority of idiots and imbeciles accompanied by corresponding bodily weaknesses of some sort.

Idiots and imbeciles differ much in their capacity for further development under even favourable circumstances. Some can be greatly elevated towards the standard of average humanity, and can even be rendered fit to earn their own livelihood in simple trades or manual labour, while others cannot be in any way improved. They are especially subject to certain bodily diseases of degeneration, such as scrofula, consumption, rickets, and diseases of deficient nutrition generally. Two-thirds of idiots die of consumption. The great aims in treatment are to improve the bodily nutrition, the nervous and muscular action, and the habits, to teach co-ordinated movements and simple employments, such as gardening, mat making, carpentering, &c., and to evolve the possible intelligence by an education through the senses. Some of them have one faculty or capacity fairly or even extraordinarily developed, while the general mental power is weak. Some are good musicians. Some can calculate well, while others are ingenious in constructiveness. Such faculties have in those cases to be especially cultivated. For this purpose good food, exercise, drill, warmth, fresh air, and music are necessary, and a careful study and testing of each case to find out its strong and weak points; and teachers who devote themselves to this particular kind of educative process are required. For most of them this can only be done in Training Schools for Idiots and Imbeciles, of which there are about twelve fully equipped in the United Kingdom. It is felt by many persons that in addition to these a kind of school is needed between them and the ordinary school, for the purpose of developing 'backward children,' of whom there are a considerable proportion in our schools—a deadweight on our teachers and on the progress of the ordinary scholars. Education should be suited to the educability and the inherent brain capacity of the scholar. Congenital idiots and imbeciles may have *attacks of acute insanity*, for which they may need to be sent to asylums for the insane; but as a general rule such institutions are not suitable for them. Few benefactors of their kind deserve more honour than the pioneers in the right treatment and education

of idiots and cretins, such as Reubl, Howe, Seguin, and Guggenbuhl. Few things must have looked so disheartening, unattractive, and unpromising of good results. But from a scientific point of view, both psychologically and physiologically, the undeveloped minds and bodies of this class have great interest and high importance.

Ireland classifies idiocy into ten divisions: (1) Genetous, (2) Microcephalic, (3) Eclampsic, (4) Epileptic, (5) Hydrocephalic, (6) Paralytic, (7) Cretinic, (8) Traumatic, (9) Inflammatory, and (10) by deprivation of the senses. From this it is seen that there are many pathological causes of the disease. It is a popular error to suppose that all idiots have small heads. Three-fifths of them have larger heads than average men, and only a few (the microcephalic) are small-headed. It is quality more than quantity of brain that counts for mind. *Cretinism* is a very interesting variety of idiocy and imbecility, and is the subject of a separate article. The general causes of idiocy have not yet been fully made out. It is unquestionably hereditary in at least 50 per cent. Consanguine marriages are the cause of idiocy beyond doubt, but only when the stock is bad, and so any tendency to nervous disease in the parents is doubled in the children. Scrofula is another fertile source of this degeneration of humanity, and there is ground to believe that frights to the mother when pregnant cause a small proportion of the idiocy of the world. But idiots are born in apparently perfectly healthy families. Evolutionally idiocy, imbecility, and cretinism may be looked on as reversions to a lower type, and so an example of one of nature's ways of bringing a bad stock to an end by stopping reproduction. Idiots and imbeciles are regarded as children all their days by the law, and provisions are made for the appointment of tutors and curators for them. They are held irresponsible for their acts. See Dr W. W. Ireland, *Idiocy and Imbecility* (1877).

Idiosyncrasy. See ANTI-PATHY.

Idle, a town in the West Riding of Yorkshire, near the Aire, 3 miles N. by E. of Bradford, like which it is a seat of the woollen manufactures. Pop. of township (1851) 7118; (1891) 14,462.

Idocrase. See VESUVIAN.

Idolatry is the worship paid to an image which is held to be the abode of a superhuman personality. It is widely spread among primitive religions, as the ideas underlying it form an essential part of the savage philosophy of the universe everywhere. Yet it is not itself a primitive worship, being absent among Bushmen, Hottentots, Fuegians, Veddas, and Eskimo, while present in the great civilisations, as the Egyptian, Chaldean, Indian, Greek, and Roman, and nowhere in more splendid development than in the Mexican and Peruvian. The idol, as something visible and concrete, helps the savage to give a definite form to his vague ideas of higher beings, just as the doll embodies to the child the notion of distinct personality. We may dismiss the idea that idolatry represents a decadence of the religious sentiment, degenerating from a conception of the Divine as absolute spirit to its symbolical representation under human or animal forms. In reality it marks a stage of progress in religious growth, when man rising above the vague adoration of personified objects, conceives of gods under the form judged most worthy of their habitation. In theological phraseology the term idolatry is often used loosely as covering all forms of worship of seen as opposed to unseen existences, thus including *idolatry*, *deity-worship*, *adoration*, *prostration*, *salute*, and even such forms of worship as *prostration*. The earlier stages of idolatry are *animism*, or the worship of

mere objects personified, and *animism*, or the belief in spirits as distinct from things and accustomed to exercise influence upon the affairs of men. It is incorrect to say that idols invariably begin with being symbolical representations, and are next taken for the image, and lastly for the body itself of the divinity, though forgetfulness of their primitive signification. And all images which represent a superior being and are worshipped are not idols, but only those which are believed to be conscious and animate. Yet the distinction is not precise, and indeed within the range of the same religion the images of the Divinity remain for some animate individualities, actual embodiments of spirits; for others mere symbols, like the Madonna and Child which help to warm the piety of the faithful in Catholic countries, or the photograph which brings a distant mother the more distinctly to the memory of an Australian colonist. In course of time the idol tends to become confounded with the idea of which it was the symbol, hence superstition and delusion ensue; but the missionary's iconoclastic zeal is often as unintelligent as the grown man's indignation at the child fondling its doll. It must not be forgotten that the savage mind is ever prone to confound a subjective relation with an objective one. To make the image of an object for him is to reproduce it, and by means of the portrait he passes easily to the notion of reaching its original.

There is a continuous transition from fetichism to idolatry, and the one is commonly the antecedent of the other. Fetichism is strictly the belief that the possession of an object can procure the services of the spirit lodged within its interior, and hence any material object is capable of being made a fetich, provided only it is capable of being appropriated. Naturally the fetich of stone or wood is the one most easily transformed into an idol, and early it is carved, shaped, and polished, like the Greek *xoanon*, or ornamented with coloured feathers or the like. A new step is taken when on the summit of the stone or column there is shaped a human head, like the *hermae* of the Greeks; and once the head is formed the rest of the figure follows naturally. Idols are most often more or less artistic imitations of the human form, often made colossal or monstrous to represent added power or dignity; and it is a somewhat striking development of commercial Christianity that there is an active manufacture of these in our own city of Birmingham and elsewhere, to be sent out to India, it may be, in the same ship with the missionaries. To the savage mind the animal is the equal of man, and it is quite natural that it also should become the dwelling-place of a divinity, either in its ordinary form or in mixed human and animal forms, like the monstrous creations of the ancient Chaldeans. But in general the human form predominates in the conception of gods, because the natural anthropomorphism of man attributes to his deities human thoughts and feelings, and thus ends with lending them also a human physiognomy. Even such developments of idolatry as the apotheosis of the phallic emblem and its representation in wood or stone is but a specialised form of the anthropomorphic spirit.

Idols which receive the worship of a nation or a tribe are a simple development of fetiches in human form which belong to individuals. Thus side by side with idols which are the object of public worship we find others that are merely individual or domestic fetiches, like the small figures buried by the ancient Egyptians in their graves, and the *teraphim* which Rachel stole from Laban, and hid in the camel's furniture on which she sat. The worship of the dead may also lead us to idolatry by the same transitions as the worship of spirits,

They form a large and powerful class of spirits; and it is natural that some receptacle should be found for them. Again, the elemental idea that after death the spirit continues to reside in the body, or in some portion of it, as a bone or the skull, explains the philosophy of placing a statue of the dead man beside his grave. The Maori *atua* or ancestral deity deigns to enter his carved wooden image through the incantation of a priest, in order temporarily to deliver oracles. Tiele has shown us that the *nirgalli*, those representations of monsters so common outside the Chaldean palaces, had for their aim to offer alternative dwelling-places to malignant spirits, especially those of diseases.

A striking feature of idolatry is its tendency to revive even under the shadow of purer spiritual ideas. The proneness of the ancient Jews to lapse into the idolatry of the neighbouring races, despite the lofty conception of monotheism which was early grafted by the Semitic consciousness and is still maintained within the wide range of Islam, is paralleled by the modern Brahman return to a practice abhorrent to the ancient Vedic religion, as well as the universal Buddhist adoration of statues and relics of a founder pre-eminent among men for the pure spirituality of his teaching. And even within the range of Christianity itself such fantastic absurdities as winking and weeping statues, and the periodical liquefaction of a saint's blood sixteen centuries old are conceptions in perfect keeping with the devices of an idolatrous priesthood in Polynesia or Central Africa.

See the articles ANIMISM, ANIMALS (WORSHIP OF), FETICHISM, IMAGE-WORSHIP, and RELIGION; the works of Spencer, Waitz, Schultze, Kéville, and Girard de Rialle, *passim*; and particularly E. B. Tylor's *Early History of Mankind* (chap. vi.), and *Primitive Culture* (chap. xiv.); and Goblet d'Alviella's admirable study, 'Les Origines de l'Idolâtrie,' in the *Revue de l'Histoire des Religions* (vol. xii. 1885).

Idria, a mining-town in the Austrian crown-land of Carniola, celebrated for its quicksilver mines (discovered in 1497), is situated 1093 feet above sea-level in a deep, cañon-shaped valley, on a river of the same name, 23 miles W. by S. of Laibach. Upwards of 230 tons of quicksilver are produced annually, and about 20 tons of cinnabar (red sulphuret of mercury). Pop. 4984. The miners number 1300; about 1000 of the women are employed in lace making.

Idris, a mythical figure in Welsh tradition, supposed to have been at once a giant, a prince, and an astronomer. On the summit of Cader Idris (q.v.) in Merionethshire may be seen his rock-hewn chair, and an ancient tradition told that any Welsh bard who should pass the night upon it would be found next morning either dead, mad, or endowed with supernatural poetic inspiration. This tradition forms the subject of a fine poem by Mrs. Hemans; the gigantic size of the chair is alluded to in Tennyson's *Geraint and Enid*.

Idrisi. See EDRISI.

Idumaea. See EDOM.

Idna, or IDNA, the name of a goddess of the northern mythology. She was the daughter of the dwarf Svadd; but being received among the Æsir, she became the wife of Bragi. See SCANDINAVIAN MYTHOLOGY.

Idyll (Gr. *eidullion*, Lat. *idyllium*, 'a little image'; a term generally used to designate a species of poem representing the simple scenes of pastoral life. It is, however, an error to suppose that the idyll is exclusively pastoral; certainly there is no warrant for such a notion in the usage either of the ancients or the moderns. Of the thirty *Eidyllia* of Theocritus not more than one

half are pastoral in their character. After the use made of the word by Tennyson in his *Idylls of the King*, which are epic in their style and treatment, and romantic and tragic in their incidents, it becomes very difficult to say what may not be called an idyll.

Il, a rocky island in the Gulf of Marseilles, crowned by a castle, the Chateau d'Il, which was built by Francis I. of France, and subsequently used as a state-prison. Here were confined, amongst others, Mirabeau and the Duke of Orleans (Philip Egalité), not to mention 'Monte Cristo.'

Ili, a small seaport in southern Morocco, 35 miles S. of Aguilon, ceded to Spain in 1883 in fulfilment of a clause in the treaty signed between the two countries so far back as 1860.

Iggdrasil. See YGGDRASIL.

Iglau (Bohm. *Jihlava*), the second largest town of Moravia, is situated 1703 feet above sea-level, on the river Jglawa, close to the Bohemian boundary, 123 miles NNW. of Vienna by rail. It has some old churches (one founded in 799). Its staple industries have always been the manufacture of cloth and woollen goods; glass and tobacco are also manufactured. It has a large trade in corn, flax, wool, cloth, and timber. Pop. (1880) 12,378; (1890) 23,716. Here in 1436 the Emperor Sigismund signed the Prague Compactata, after which he was accepted as king by the Bohemians. In the Thirty Years' War it was taken by the Swedes and recaptured by the Imperialists.

Igloodik, an island near the east end of the Fury and Hecla Strait in the Arctic Ocean, is the place where Parry passed the winter of 1822-23.

Ignatieff, NICOLAUS PAVLOVITCH, Russian diplomatist, was the son of General Paul Ignatieff, a favourite officer of Alexander II. He was born at St Petersburg on 29th January 1832, and educated in the corps of pages. In 1856 he exchanged from the military to the diplomatic service. In 1858 he induced China to give up to Russia the Amur province; and in 1860, having been appointed ambassador at Peking, he secured for his country from China the southern portion of the Maritime Province lying east of the Amur. Between the two treaties by which Russia thus gained footing on the Pacific, Ignatieff concluded with Khiva and Bokhara commercial treaties advantageous to his own country. In 1867 he was made ambassador at Constantinople, at which court he had represented Russia since 1864. He there acquired considerable influence over the Sultan and amongst the Turkish statesmen. An ardent Pan-Slavist, he is suspected of having intrigued with the Slav states of the Balkans in the interests of Russia. In the diplomatic proceedings before and after the Russo-Turkish war of 1878 Ignatieff took a principal part as Russia's representative. The treaty of San Stefano was principally his work; and he was greatly incensed when it was decided to submit its conclusions for revision to a European conference at Berlin. After Alexander III. came to the throne Ignatieff was appointed minister of the Imperial Domains, and in 1881 succeeded Prince Loris Melikoff as minister of the Interior. In this capacity he endeavoured to stamp out Nihilism by forcible measures, but unsuccessfully. He was dismissed at the end of the year, apparently because of his Pan-Slavist intrigues, and for having shut his eyes to the persecutions of the Jews.

Ignatius, one of the so-called Apostolic Fathers, about whom information is but scanty down to the time of Eusebius, except in so far as may be gained from the much-disputed epistles associated with his name. His birth and education

are wrapped in obscurity, but from the letters it may be inferred that he was not born of Christian parents, but was converted in mature life, and that his earlier life had been such as to fill his later years with remorse and give an unusual intensity to his religious convictions. The name is Roman; the second name, Theophoros, is merely a second name and not a title of honour ascribed to the saint. It was often interpreted as 'the God-borne,' as Ignatius was said to be the child our Lord took in his arms (Mark, ix. 36, 37), but this story was unknown in the early centuries. Eusebius is silent about it, and Chrysostom says distinctly that Ignatius had not seen the Lord. Origen makes him the second of the Antiochene bishops, and in Jerome's revision of the *Chronicon* of Eusebius he is stated to have been, with Papias and Polycarp, a disciple of St John. The usual date for his accession is 69 A.D., and of his martyrdom 107, but all that can be said with certainty is that his martyrdom fell about 110. The letters show that he was condemned to the wild beasts at Antioch, and that he was carried to Rome by a maniple of soldiers merely for the execution of his sentence. On the journey he was joined at Smyrna by representatives from the churches of Tralles, Magnesia, and Ephesus. Here he wrote four letters which are extant; three to the churches whose delegates had met him—the Ephesians, the Magnesians, and the Trallians; the fourth, to the church of the Romans, whither he was journeying. The first three are mainly concerned in enforcing lessons of doctrinal truth and ecclesiastical order; the fourth is occupied almost entirely with the thought of his approaching martyrdom. Next from Troas he wrote three letters: the first and second to the churches of Philadelphia and Smyrna, which he had just visited; the third to Polycarp, bishop of the latter. The general topics treated are the same as in the first three, but special charges are laid upon Polycarp to exhort the brethren at Antioch. We next hear of him at Philippi, as we learn from Polycarp's extant reply to the Philippians, who had evidently asked Polycarp for copies of the letters of Ignatius—not improbably the very cause of their preservation. Beyond this point we know nothing more of Ignatius save that at Rome he earned his martyr's crown. The tragic interest of his journey to face his doom in the arena, and the noble and exalted heroism of his enthusiasm as the vision of martyrdom for his Lord opened up before his eyes, left his dying letters a precious heritage to the church and gave an added sanctity to his teaching.

About the close of the 4th century we meet the persistent statement that the relics of Ignatius had been carried from Rome to Antioch, and we find October 17 fixed as the day of his martyrdom. The bones were finally deposited in the Tycheum or Temple of Fortune, which henceforward became known as the Church of Ignatius. His reputation was great, as is evinced by the epistles forged or interpolated in his name; the legendary acts of martyrdom, which give the unhistorical but well-known interview with Trajan; the translation of his letters into Syriac, Coptic, and Armenian, honoured especially by the Monophysites, who fancied they found support in them for their distinctive tenets. And from the close of the 16th century the Jacobite patriarchs of Antioch have regularly assumed the name of Ignatius on their accession to the see.

The Ignatian epistles exist in three different forms or recensions. The *first* of these contains three epistles alone: to Polycarp, to the Ephesians, and to the Romans. It is extant only in a Syriac version. The *second* presents these three epistles in a fuller form, and adds to them four others: to

the Smyrneans, Magnesians, Philadelphians, and Trallians. Besides the original Greek this form is found in Latin, Armenian, Syriac, and Coptic translations, although only fragmentarily in the last two. The *third* contains the seven epistles already mentioned in a still longer form, together with six others—a letter from Mary of Cassobola to Ignatius, and letters from Ignatius to Mary of Cassobola, to the Tarsians, the Antiochenes, to Hero, and to the Philippians. This recension is extant both in the Greek and in a Latin translation. These three it is now usual to call the *Short*, *Middle*, and *Long* recensions. As will be seen, of the twelve Ignatian epistles (excluding that of Mary to Ignatius) three occur in three different forms, four in two forms, and the remaining five in one form only. The Long recension is now universally condemned as spurious. More serious is the dispute between the remaining two, which are often spoken of, from their editors, as the Curetonian (*Short*) and the Vossian (*Middle*) versions. The Curetonian long held the field, but the genuineness of the Vossian letters is now the prevailing belief, and is every day gaining ground. Bishop Lightfoot began by believing in the Curetonian form, but gradually found that the position demanded too much ingenuity from the Ignatian forger, and at length, influenced greatly by Zahn, found himself compelled to believe in the seven Vossian epistles as representing the genuine Ignatius. Indeed the priority and substantial genuineness of the Vossian letters may be said to be proved, in so far as any question of the kind can be proved, by Lightfoot's work; and with this conclusion one of the main buttresses of Baur's scheme of the formation of the Christian canon and of early Christian history generally falls to the ground.

The Short Form, represented only by a Syriac version, was first published by the Rev. W. Cureton in 1845, from MSS. recently brought to the British Museum from the Nitrian desert. Not only are the epistles fewer in number, but shorter and more abrupt. Their upholders believe the Greek form an expansion and corruption of the lost Greek originals of these Syriac letters; while their opponents think the Syriac an abridgment of the Greek.

The Middle Form was first published in the Latin version (made perhaps by Robert Grosseteste), by Cusshier (Oxford, 1644), from two MSS. discovered in England; the original Greek, by Isaac Voss (Amsterdam, 1646), from a Medicean MS., the epistle to the Romans alone excepted, which was first published by Ruyart (Paris, 1689). The Armenian version appeared at Constantinople in 1783. These may now be accepted with some confidence as the seven epistles of Ignatius mentioned by Eusebius, which were translated into Syriac soon after his time, and of which the Curetonian epistles are merely an extract.

The Long form in its Latin version was printed by J. Faber Stapulensis (Paris, 1498); in the Greek version by Valentinus Paccus (Dillingen, 1557). These epistles are supposed to have been interpolated and extended by the pseudo-Ignatius in the later half of the 4th century.

The chief differences in substance of these three forms of the Ignatian epistles are these: the Curetonian text contains no quotation from the Old Testament, and very few from the New, while the Vossian contains a considerable number of quotations, and the Long a large number. Again, the last also contains many allusions to religious institutions not in existence in a mature state before the 4th century, as well as plagiarisms from preceding writers and perceptible differences in doctrinal teaching. There is a tendency to maintain the supremacy of the Father and to make the Son's agency dependent. Indeed, many passages savour distinctly of Apollinarianism, yet the general bearing of the language leans faintly to the Arian side. The whole might well be an ingenious

palmed off by a pious fraud upon the name of a venerated primitive father of the church. The style and expression throughout drive us to the conviction that the six additional letters come from the same hand which interpolated the seven.

Again, the Vossian letters are found to be distinctly antagonistic to Docetism. Indeed, a characteristic note of Ignatian theology throughout is the accentuation of the twofold nature of Christ—his deity and his humanity. The advocacy of the episcopal office appears definitely in the Short no less than the Middle form; and the abridgment must have been made rather for purposes of edification or practical convenience rather than for Monophysite reasons, as C. Wordsworth maintained, or for any other doctrinal purpose. In short the abridgment theory is much more rational and easy than the expansion theory, and if we are to accept the latter we must maintain, says Lightfoot, that the pseudo-Ignatius was a prodigy of minute observation, of subtle insight, of imitative skill, of laborious care, which is probably without a parallel in the history of literary forgeries, and which assuredly was an utter impossibility among the Christians of the 2d and 3d centuries.

The prominence and authority of the episcopal office in the Ignatian epistles has proved a grave stumbling-block to many scholars. It is certainly sufficiently clear throughout, yet it is merely as the embodiment of the idea of order and the guarantee of unity within the church. It is not upheld exclusively as against other forms, while all tinge of sacerdotalism is absent, as well as such an argument as that in Irenæus, who lays stress on the apostolic succession as a security for its faithful transmission. Nor is it autocratic by any means, while its spread is not yet uniform throughout Christendom, as at Philippi, for example. Evidence of a localised episcopate within the Gentile churches is absent, and nowhere is there any trace of the notion of a distinct diocese, while there is no reference to any developed ritual of public service. Six of the epistles are full of the necessity of obedience to bishops, which is alone wanting in the seventh, that addressed to the Romans, who it may legitimately be inferred had not yet adopted the form of government which Ignatius elsewhere commended with such warmth.

See Cureton, *Antient Syrian Version of the Epistles of S. Ignatius*, &c. (1845), and his *Copius Ignatianum* (1849); the works in his support by Bunsen, A. Ritschl, E. A. Lipsius, and those against his theory by Baur and Hilgenfeld, who denied the authenticity of any recension. A fatal blow to Cureton's theory was dealt by the able and learned work of Zahn, *Ignatius von Antiochien* (1873), which won over Lipsius, and now holds the field, its most formidable champion being the late Bishop Lightfoot, whose work, *The Apostolic Fathers, Part II., S. Ignatius and S. Polycarp* (2d ed., 3 vols., 1889), contains all materials necessary for a complete study of the question, and is a masterpiece of profound erudition and conclusive argument hardly to be equalled in the whole range of English or German scholarship.

Ignatius' Beans. SAINT, the seeds of the *Ignatia amara*, formerly *Stychnium Ignatii*, a tree of the natural order Loganiaceæ, and nearly allied to that which produces *Narcomeia* (q. v.), a native of Cochin China and of the Philippine Islands. The fruit is of the size of a large pear, and contains about twenty brownish seeds, of about the size of olives, rounded on one side, and somewhat angular on the other. They contain *strychnin*, but no larcina, and their medicinal uses are similar to those of *narcomeia*.

Ignatius Loyola. See LOYOLA.

Igneous Rocks are those which have been erupted from the heated interior of the earth: hence they are also termed *eruptive rocks*. Petrologically they may be grouped under two heads—*crystalline* and *fragmental*. The crystalline division includes many rocks which are rather vitreous or glassy than crystalline, while a large number are composed partly of crystalline and partly of non-crystalline materials. No quite satisfactory classification of the 'crystalline' igneous rocks has as yet been possible, perhaps the most convenient being that which is based on the nature of the principal rock forming minerals. Thus, those in which orthoclase (see FELSPAR) is a dominant ingredient are grouped together as *Orthoclase rocks*. In another large class plagioclase felspars play a principal part, and thus we have the *Plagioclase rocks*, and so in like manner *Nepheline* and *Lenticite* rocks, and *Olivine* and *Serpentine* rocks.

(1) *Orthoclase Rocks*.—Some of these rocks contain much free silica (Quartz, q. v.), while others contain little or none. They are thus divided into two groups—*Quartziferous* and *Quartzless*. Under the first group come *Granite*, *Quartz-porphry*, and *Liparite*, while under the second are ranged *Syenite*, *Orthoclase-porphry*, and *Trachyte*. Some of these rocks are holocrystalline—i. e. composed entirely of crystalline ingredients, as granite and syenite; others, such as liparite and trachyte, are only semi-crystalline—they contain in addition to crystalline constituents a larger or smaller proportion of non-differentiated mineral matter. *Obsidian* and *Pebble-stone* are vitreous species of orthoclase rocks which consist almost entirely of volcanic glass. Other kinds of orthoclase rocks have been recognised by petrologists, but those mentioned are the most important.

(2) *Plagioclase Rocks*.—Most of the rocks in this division are distinguished by their basic character—that is to say, they contain generally less silica than orthoclase rocks. The most important species are *Diorite* (a crystalline granular aggregate of plagioclase and hornblende), *Andesite*, *Porphorite*, *Basalt*, and *Gabbro*. The holocrystalline character is seldom met with in this division; it occurs, however, in diorite and gabbro. The other species mentioned usually contain some admixture of non-differentiated mineral matter. Vitreous varieties also occur in this division. See BASALT.

(3) *Nepheline and Lenticite Rocks*.—The rocks included under this head closely resemble the basalt rocks of the preceding division, plagioclase being substituted in whole or in part by nepheline or lenticite or by both. See BASALT.

(4) *Olivine and Serpentine Rocks*.—These are generally rather basic rocks. The olivine rocks proper, or *Peridotites*, as they are called, contain olivine as their principal constituent. They often show more or less alteration, the olivine being replaced in whole or in part by Serpentine. Some olivine rocks, indeed, have been completely altered into serpentine.

The *fragmental* igneous rocks consist of the loose ejectamenta which have been erupted from volcanic orifices. These rocks are frequently consolidated, and when fine-grained it is sometimes

FIG. 1.—NECK FILLED WITH FRAGMENTAL IGNEOUS ROCK.

difficult without the help of the microscope to distinguish them from compact crystalline igneous rocks. Some account of these rocks will be found under AGGLOMERATE, TUFF, VOLCANO.

Igneous rocks, when looked at from the point of view of the student of structural geology, are classified in an altogether different way. It is not only necessary to know the petrological character of a rock—we must discover something of its history. Was it extruded at the surface like the ejecta of modern volcanoes, or did it cool and consolidate below ground? Thus two kinds of igneous or eruptive rocks are recognised by geologists: (1) *Eufœnic rocks*, consisting of lavas, tuffs, &c., which have been ejected at the surface, either upon the land or under water; (2) *Plutonic or Hypogœic rocks*, which, whether consisting of crystalline or fragmental materials, have not been so extruded, but are now exposed owing to the denudation of rock-masses underneath which they were formerly concealed. The volcanic rocks are often termed *contemporaneous*, i.e. they belong to the same geological age as the strata with which they are *interbedded*. On the other hand, the *plutonic* rocks are described as *intrusive* or *subsequent*, because they have been *intruded* amongst, and therefore must be *subsequent* in date to the rocks with which they are in contact.

(1) *Contemporaneous Igneous Rocks*.—These consist of crystalline (lava flows) and fragmental rocks (tuffs, &c.), and are simply the products of former volcanic action. They are met with at all geological horizons from the oldest down to the most recent period. Sometimes they indicate the former existence of small isolated 'puys' (see VOLCANO), from which it may be only a single eruption took place; at other times they are obviously the products of much more powerful and long-continued volcanic action. Many of the hill-ranges of central Scotland (for example, Siddlows, Ochils, &c.) are built up of successive lava flows with associated tuffs, which have been ejected from vents in the manner of modern volcanic eruptions. In some regions, however, there occur vast successions of lava-flows, covering immense areas, which do not appear to have been erupted from isolated vents, but are believed to have welled up along the line of great fissures, and to have poured in wide floods over the surface, so as eventually to form extensive plains or plateaus. The rocks of such 'fissure-eruptions' consist usually of basalt, with basalt tuff or Palagonite. The basalt plateaus of the western territories of North America, of Iceland and the Faroes, of the Deccan (India), and of Abyssinia are good examples; while in Antrim and in many of the western islands of Scotland fragments of similar plateaus may be studied.

An interbedded or *contemporaneous* lava-form rock may often be distinguished from an *intrusive*

vent. These latter, in countries where volcanic action has been long extinct, no longer exist as crateriform hollows. The upper parts of the cones have all been swept away, and only the stumps remain. These stumps are known as *necks*, by which is understood a more or less cylindrical funnel or volcanic vent filled up either with fragmental or crystalline rock or with both. Such necks vary in diameter from a few yards up to several hundred feet; sometimes they occur upon a line of Dislocation (q.v.) or fault; at other times they have no such connection. The necks now described are probably the relics of comparatively small volcanoes like the puys of Auvergne and the Eifel. Now and again, however, as in some of the hill ranges of central Scotland, necks of a larger size are met with. These vary from 100 yards or so up to a mile or more in diameter, and are usually plugged up with crystalline igneous rock, although fragmental rock also is occasionally present. Such necks seem to be the stumps of great volcanic vents, from which the lava-form and fragmental igneous rocks of the surrounding neighbourhood were ejected. Good examples occur in the ranges of the Siddlows, the Ochils, the Braids, &c. *Bosses* is the term applied to irregular-shaped masses of crystalline igneous rocks, which appear to be for the most part of deeper-seated origin than those of the necks just referred to. The rocks of these bosses are usually more or less coarsely crystalline, and often have a granitoid aspect, such as granite, syenite, gabbro, &c. Bosses usually cover a considerably wider area than necks, and it has been conjectured that they are merely the most deeply seated portions of ancient volcanoes—the reservoirs from which molten matter was pumped up to the surface. *Intrusive Sheets* are masses of crystalline

Fig. 3.—Intrusive Sheet and Dykes: *i*, igneous intrusive sheet; *d, d*, dykes; *s, s*, sedimentary strata.

igneous rock which have been erupted between the planes of bedding of pre-existing strata. They are never scoriaceous or slaggy, and are generally markedly crystalline in texture, especially when the sheet is thick. Their intrusive character is often betrayed by the baked appearance of the beds which overlie them; by the fact that they seldom keep quite to one and the same plane, but sometimes break across the overlying beds and continue their course along a somewhat higher horizon; and by the veins and protrusions which not infrequently proceed from them. *Dykes* are vertical wall like sheets of igneous rock, which may vary in thickness from a foot or so up to 30 yards or more. They often run persistently in one direction for many miles. Occasionally they divide into two or more branches, and now and again they send out veins into the surrounding strata. The rock most frequently met with in such dykes is basalt. Sometimes dykes rise along the lines of faults, but this is by no means general. *Veins* is the term applied to the more irregular, winding, branching, and tortuous smaller intrusions of igneous rock. They may consist of any kind of crystalline rock. Dykes and veins are frequently found proceeding in all directions from bosses, as in the case of granitic masses. From the smaller puy like necks also veins and dykes have occasionally been injected into the surrounding rocks, while these and

Fig. 2.—Contemporaneous and Intrusive Igneous Rocks: *p, p*, contemporaneous trap-rocks; *f, f*, contemporaneous fragmental igneous rocks; *i, i, i*, intrusive igneous rocks.

sheet of crystalline igneous rock by noting that the beds which immediately overlie it show no trace of having been subjected to the action of heat. The upper part of the lava-form rock is not infrequently scoriaceous or amygdaloidal (see AMYGDALOID) in character, and fragments of this crust may occasionally be found in the overlying beds if these chance to be of aqueous origin.

(2) *Intrusive Igneous Rocks*. These rocks are likewise met with under two forms, *crystalline* and *fragmental*. The *fragmental* intrusive rocks are found only in connection with old volcanic

extensive sheets may often be traced proceeding from the larger kinds of necks. The rocks surrounding bosses, and traversed by veins, are often highly metamorphosed.

Ignis Fatuus (Lat. *ignis*, 'fire,' *fatuus*, 'foolish') is a luminous appearance of uncertain nature which is occasionally seen in marshy places and churchyards. The phenomenon has been frequently described, but it has been observed so rarely in favourable circumstances by scientific men that there is no satisfactory explanation. The light usually appears in autumn evenings shortly after sunset; it is common in the north of Germany, in Italy, in the south and north-west of England, and on the west of Scotland, but it has been noticed in many other countries.

Descriptions of ignis fatui vary so much that several different phenomena have evidently been included under the name. The light usually resembles a flame, and is often mistaken at first for the light of a lantern, but seen more closely the colour appears as bluish, reddish, greenish or yellowish, merging into purple, but never a clear white. Some observers describe the flame as fixed in position, shining steadily either close to the ground or a few feet above it, and illuminating the surrounding reeds and grass. Others have seen it in motion bounding rapidly over the country, and sometimes rising high in the air. The light has been seen to divide repeatedly into several smaller flames, which describe complicated movements, advancing, retiring, and combining. The moving light is said to recede from an observer who approaches it, but to follow him if he retires from it.

Some supposed appearances of the ignis fatuus have been proved to be the lights of distant houses seen through trees; others are almost certainly due to luminous insects, such as the glow-worm, or to the phosphorescence of decaying vegetable matter. St Elmo's Fire (q.v.) has also been confounded with it. But setting all these possible cases aside, both fixed and moving ignes fatui have been proved to exist. The spectrum of the light has never been observed, so far as the writer can ascertain. It is said that paper has been ignited by the flame, and if this be so there must be at least two similar phenomena of different nature. List in north Germany passed his hand through the luminous appearance and felt no warmth; near the same locality at a later date Knorr held the metal tip of a walking-stick in the flame of a fixed ignis fatuus (which he could not himself touch on account of the marsh) for a quarter of an hour, but the metal was not warmed. In the former instance a puff of air extinguished the flame, and a very slight explosion was heard when it reappeared; in the latter a strong waft of air only made it flicker slightly, and a light breath produced no effect. No odour was perceptible.

The common hypothesis that ignis fatuus is the flame of burning marsh-gas, CH_4 , is untenable, for although this gas is produced abundantly in many marshy places it cannot ignite spontaneously. The more plausible suggestion that phosphuretted hydrogen, PH_3 , which is spontaneously inflammable, might be produced in churchyards or marshes where there is decaying animal matter, does not account for the effect observed by the German physicists, since no gas can burn without giving out heat, and that particular gas has a very penetrating and characteristic smell. Nor could a burning gas, except on the most extravagant assumptions, bound over the country like a ball of fire for half an hour at a time. The early supposition of a phosphorescent vapour is more reasonable, although excepting that of free phosphorus, which would not occur in nature, no such vapour is known

to exist. The phenomenon was undoubtedly more common a century ago than it is now, and its disappearance in many localities may be directly traced to the draining of tens and marshes.

Popular names—e.g. Will-o'-the-Wisp, Jack-a-Lantern, Spunkie, &c.—abound in folklore, and are connected with many stories of travellers mistaking the marsh lights for a cottage window, and being decoyed into dangerous places, often with fatal results. A German legend identifies the will-o'-the-wisp with the soul of an unbaptised infant; an Irish, with a soul broke out of Purgatory. For the folklore of the subject, see *Notes and Queries*, *passim*.

Ignoramus (Lat., 'we do not know'), the word formerly written by a grand-jury on the back of an indictment, meaning that they rejected it. The word is now used most commonly as a synonym for a blockhead.

Ignorance (*Ignorantia juris*) is held in law to be no excuse for any breach of contract or duty, nor for crime or other offence. It is absolutely necessary to start with this maxim, otherwise it would be quite impossible to administer the law; for if once a contrary maxim were allowed it would not only be a premium to ignorance, but would lead to endless and abortive inquiries into the interior of a man's mind. Ignorance of a fact, however, is a different thing. Another kindred maxim of the law is that every man intends the consequences of his own act. Thus, if he shoot at or give poison to a person it is presumed that he intended to kill such person. So, if he leave a trap-door open in a street or thoroughfare it is held that he intended people to fall into it and be injured. There is, however, a doctrine called *bona fides*, which, in the case of petty offences punishable by justices, often tempers the strict and rigid application of the maxim, *ignorantia juris neminem excusat*; and even in crimes a judge always takes into consideration, when passing judgment, whether the prisoner or defendant was an ignorant or intelligent person.—In Catholic theology, a man is never excused for sin, whether of omission or of commission, on the plea of ignorance which he can be fairly expected to overcome, of 'vincible' or wilful ignorance; whereas 'invincible' ignorance, which a man could not help or abate, altogether excuses from guilt.

Ignorantines, a religious congregation of men in the Roman Catholic Church, devoted to the gratuitous instruction of poor children, now better known as the Brothers of Christian Schools. See *SCHOOLS*.

Igalada, a town of Spain, 32 miles NW. of Barcelona, on the west side of Mount Montserrat. It carries on manufactures of cotton and woollen goods and firearms. Pop. 11,900.

Iguana, a genus typical of the Iguanidae, a family of thick-tongued lizards representing in the New World the Agamidae of the Old. The family comprises fifty-six genera, most of which are found in tropical America. They are slender and lizard-like in form, have distinct eyelids, the tympanic membrane usually free, the tail long and compressed, the toes five, five on each limb, and ending in a sharp claw. They are arboreal in habit, and feed chiefly on leaves and fruits, but will also eat insects. The genus *Iguana* includes five species, found in the West Indies and South America, and all characterised by a pyramidal head, a pouch of skin under the throat, and an upright comb of pointed teeth extending along the back from the neck to the tip of the tail. The best known is the Common or Green Iguana (*I. tabourinatus*), which has a very large pouch, is predominantly of a beautiful green colour, and grows to a length of

from 3 to 5 feet. This iguana lives usually in trees near a stream, climbing with great ease, and moving rapidly along the branches, but taking readily to the water, where it swims by means of its tail.

Common Iguana (*Iguana tuberculatus*).

Its flesh is white and tender, and is much esteemed for food. It is sometimes caught by noosed cords, sometimes tracked to its burrow by dogs trained for the purpose. The eggs are about the size of those of a pigeon, but have no hard shell, and are laid in the sand. They also are used as food. Other species of iguana and their eggs are eaten by those, as Darwin says, 'whose stomachs soar above all prejudices.' Other important genera are *Anolis*; *Cyclura*, one species of which, *C. Lophomus*, is called the 'great Iguana' of Jamaica; *Amblyrhynchus*, the marine lizard; *Phrynosoma*, the 'horned toad'; and the Basilisks (q.v.). See LIZARD; and Boulenger, *Brit. Mus. Cat. of Lizards* (2d ed. Lond. 1885 '87).

Iguanodon (Iguana, and Gr. *odon*, 'tooth'), a genus of remarkable gigantic dinosaurian reptiles, more abundant in the Wealden beds of Kent, Sussex, and the Isle of Wight than any other genus of associated saurians. Their singular structure, differing in many important particulars from any known reptile, long caused great diversity of opinion as to their true position. Dr Mantell, their original discoverer and learned expounder (1822),

Fig. 1. Front and side view of a Tooth of the lower jaw of the Iguanodon, about two thirds natural size.

first knew of their existence from some enormous bones, which, notwithstanding their colossal size, he considered reptilian. A large tooth next turned up, whose smooth-worn crown attested its having belonged to a herbivorous animal. Numerous other specimens of teeth were in process of time discovered, and Dr Mantell found that they corresponded in a remarkable manner with the teeth of the small American lizard, the iguana, although they exhibited very striking and important differences. The first guesses as to the creature's size,

founded on fragmentary materials, varied vastly; Mantell suggesting a length of 70 feet, Owen of 28. An extraordinary recent find of iguanodonts has simplified this and other questions as to the structure. In 1878 there were found at Bernissart, in Belgium, between Mons and Tournai, the remains of about twenty three specimens, belonging to two well-marked species; only two other species having till then been proposed. In the complete skeleton set up at Brussels from these materials the height is 14 feet 2 inches; the horizontal length of the body in a half standing attitude, 23 feet.

The structure of the skeleton is very remarkable. The front parts of both upper and lower jaws were without teeth, and suggest a hollow, beak-like arrangement; possibly the creature had a long prehensile tongue. In many respects there are striking resemblances between the structure of the ornithoid Dinosaurians (of which the Iguanodontidae are a family) and that of birds. The vertebral column had joints slightly concave on both surfaces, yet had lofty neural arches; and the sacrum was composed of five anchylosed joints, a structure found in no other reptile. The two fore-legs were small; the hinder limbs were long and strong, raising the body some distance from the ground. The leg terminated in a three-toed foot, which produced the enormous tridactyle impressions on the argillaceous Wealden beds that were for some time considered to be the footprints of huge birds. The teeth of the iguanodon, while bearing

Fig. 2. Skeleton of Iguanodon.

a general resemblance to those of the iguana, were much more complicated both in external form and internal structure than in any other known reptile. In all other known reptiles the vertically flat teeth are always sharp-edged, and fitted only to cut off the plants on which they feed; but the worn crowns in this animal show that the iguanodon thoroughly triturated its food before swallowing it.

Igavium. See GUEBIO.

Thre, JOHAN, an eminent Swedish scholar of Scottish extraction, was born at Lund in 1707, and educated at the university of Upsala, where he acquired a great reputation and carried off the highest honours. He subsequently travelled in France and England, was appointed on his return to Sweden under-librarian to the Academy of Sciences, and rose through a variety of offices to be professor of Belles-lettres and Political Economy (1748). He died in 1780. Thre's principal work is his *Glossarium Sæculi Gothici* (2 vols. folio, 1769), a work of great talent and erudition, which, though a product of the pre-scientific age, may in some respects be regarded as the foundation of Swedish philology. It was issued at the cost of the state,

which gave him 10,000 dollars to execute it. Another work of lasting value is the *Scenskt Dialect-Lexicon* (1766).

Ilchester, a decayed village of Somersetshire, on the Yeo, 5 miles N.W. of Yeovil. Supposed to be the *Ischalis* of Ptolemy, it was the principal station of the Romans in this region, and was a flourishing town in Saxon times. Numerous Roman remains have been found here. Ilchester is the birthplace of Roger Bacon. Till 1832 it returned two members. Pop. 683.

Île-de-France, one of the old provinces of France, having Paris as its capital, and now mostly comprised in the departments of Seine, Seine-et-Oise, Aisne, Seine-et-Marne, Somme, and Oise. In the middle of the 9th century it was made a dukedom, and became one of the four constituent fiefs of the French monarchy. The second duke, Odo, commonly called Count of Paris, was crowned king of France in 888. His successors contended for some years for the throne of France; one of them, Hugh Capet, founded in 987 the Capetian dynasty (see FRANCE). Île-de-France was formerly the name of Mauritius (q.v.).

Ilitzk, a town in the Russian government of Orenburg, near the confluence of the Ilek with the Ural. Pop. 5769. Close by is the richest salt-bed in Russia, yielding close upon 21,700 tons of salt annually. It was discovered by Pallas in 1769, and visited by Murchison in 1850.

Ilm. See DIGESTION.

Ilms, or ILMAC PASSION. See COLIC.

Ilex, a tree often named in the Latin classics, the Evergreen Oak or Holm Oak (*Quercus Ilex*). See OAK. It is a native of most parts of the south of Europe and of the north of Africa, often attaining large dimensions, as it sometimes does where planted in Britain. It grows in general singly or in small groups, and loves the vicinity of the sea. Its leaves are ovate-oblong, acute, leathery, hoary beneath; but they vary much in some respects, from the size of a sloe-leaf to that of a beech, and from being very spiny at the edge to perfect evenness. The bark is very astringent, and is employed for tanning hides in the countries to which the tree is indigenous. Its wood is very hard and heavy, tough, durable, and useful, particularly for axles, pulleys, screws, and whatever is to be subjected to much friction. The acorns are of various quality, sometimes bitter, and sometimes sweet and eatable. In modern botany *Ilex* is the generic name of the Holly (q.v.).

Ilfracombe, a watering-place of England, is finely situated on the picturesque rocky coast of North Devon, on a cove or inlet of the Bristol Channel, 11 miles NNW. of Barnstaple (15 by a branch-line). Its air 'combines the soft warmth of South Devon with the bracing freshness of the Welsh mountains' (Charles Kingsley). This and its fine coast scenery and its admirable sea-bathing annually attract large numbers of visitors. On the north side of the (good) harbour there is a light-house, the light, 127 feet above high water, being visible for 10 miles. Although having now nothing more than a little coasting trade and fishing, Ilfracombe was in the 14th century a port of some consequence, and contributed six vessels to the English fleet for the siege of Calais. A destructive fire occurred in July 1896. Pop. (1851) 2919; (1881) 6255; (1891) 7692.

Ilhavo, a Portuguese town 40 miles S. of Oporto. Two miles distant is the glass and porcelain factory of Vista Alegre. Pop. 7800.

Ilk. See KILN.

Illicin, the bitter principle derived from Holly (q.v.).

Ilissus. See ATHENS, and METEVA.

Ilium. See TROY; and for Iliad, see HOMER.

Ilk (O.E. *gþ*, 'the same'), an old form found both in English and Scotch meaning the same. Thus, Chaucer has 'this ilk worthy knight' and 'that ilk man.' It is still not unknown in Scotland in connection with family designations; thus, 'Kinloch of that ilk' means 'Kinloch of the estate of that same name, or 'Kinloch of Kinloch.' Of that ilk' is however constantly but absurdly and ignorantly used to mean 'of that description,' as in 'carpetbaggers and politicians of that ilk.'

Ilkeston, a market town of Derbyshire, near the Erewash River, 9 miles ENE. of Derby, and 20 S. of Chesterfield. It enjoys repute from its alkaline spring and baths (opened in 1830). The parish church, with a lofty pinnacled tower, has interesting Norman and Early English features. The town-hall was built in 1868. Ilkeston has manufactures of hosiery, lace, silk, and earthenware, with coal and iron mines in the vicinity. In 1251 a charter for holding a market and fair here was granted to Hugh Fitz-Ralph; and in 1887 Ilkeston was incorporated as a municipal borough. Pop. (1861) 3330; (1881) 11,122; (1891) 19,744.

Ilkley, a watering-place in the West Riding of Yorkshire, on the Wharfe, among heathery hills, 13 miles NNW. of Bradford and 16 NW. of Leeds by a branch-line (1865). Since 1846 it has become the seat of several hydropathic establishments—Ilkley Wells House, Ben-Rhydding (q.v.), &c. It occupies the site of a Roman station, and in the churchyard are three curious Saxon crosses; whilst Bolton Abbey (q.v.) is 5 miles north-west. Pop. (1851) 811; (1891) 5767.

Ill, a river of Alsace, rising to the south-west of Basel, and flowing 127 miles north-eastward, till it falls into the Rhine 9 miles below Strasburg. It is navigable over nearly one-half of its course.

Ille-et-Vilaine, a maritime French department, formed out of the north-eastern portion of the old province of Brittany. Area, 2396 sq. m.; pop. (1872) 589,532; (1891) 626,875, mostly of Celtic race. It is watered chiefly by the Vilaine and its tributary the Ille, which unite near Rennes, the capital of the department. Ille-et-Vilaine consists of a granite plateau traversed by ranges of low hills. It is agricultural, cultivation having been greatly improved during recent years. The cider of this district is the best in France; the butter of Rennes is celebrated; the horses of the department are noted for their endurance, and are in great request for the army; and bee-keeping is prosecuted. Iron is mined; slates are quarried; and salt is extracted. The department is divided into six arrondissements—Rennes, Fougères, Montfort, St Malo, Vitre, and Redon. St Malo is the principal seaport.

Illegitimacy, by the laws of England, debars a child from the inheritance of the father, unless express provision be made by will (see BASTARD). It was even held by Mr Justice Chitty (Chancery Division, July 1889) that the term 'children' in a will does not comprise illegitimate issue, if the wording otherwise is not such as obviously meaning to include them.

The whole subject of illegitimacy forms one of the most difficult of the social problems; and there is no branch of social science in which there is such deficiency of literature. And yet its importance is sufficiently evidenced by the fact that 40,730 illegitimate children were born in England and Wales, and 10,880 in Scotland, in one year. In 1888 the illegitimate births registered in England amounted to 4.6 per cent. of the total births, and to 1.4 per 1000 living persons. The birth rate of that year was the lowest in England since the present

system of registration began; but it is noticeable that, while the marriage rate, and consequently the legitimate birth rate, has declined steadily for some years, the illegitimate birth-rate has also steadily declined. From 1841 to 1859 the proportion of illegitimate births to the total number registered ranged from 6.3 to 7 per cent.; in the ten years from 1878 to 1887 the average was 4.8 per cent.; in 1888 the proportion was 4.6 per cent. The decline is very striking, because, in the period first mentioned, the rate fluctuated between 6 and 7 per cent. with a remarkable uniformity. In the year 1845, 70 out of every 1000 births registered in England and Wales were illegitimate; in 1888 only 46 out of every 1000. Illegitimacy was greatest in the following districts, the figures here given being the illegitimate births in every 1000 births registered: Norfolk, 74; Herefordshire, 85; Shropshire, 80; Cumberland, 78; and North Wales, 73. Middlesex (extra-metropolitan) compares favourably, with 34; Yorkshire shows for West Riding 49, East Riding, 56, and North Riding, 62; and the great industrial counties come out with Durham, 40; Northumberland, 49; Lancashire, 44; Derbyshire, 43; Warwickshire, 42. The marriage rate is proportionately low. Thus, while the average marriage-rate in England and Wales in 1888 was 14.2 per 1000 persons, the marriage-rate of Hereford was 11.5; Shropshire, 11.4; Norfolk, 13.4; Cumberland, 12.6; and North Wales, 11.6. In comparing with the returns of past years we find many fluctuations in the counties; but, generally speaking, the highest rates of illegitimacy in the least densely populated districts. Unfortunately we cannot derive from this fact any conclusion referring to the education or prudential habits of the people, for in Scotland, where education is general, and thrift national, the rate of illegitimacy is notoriously high. And, as regards morals, it should be remembered that a high percentage of illegitimacy may mean that there is no prostitution.

In the year 1887 there were 10,380 illegitimates registered in Scotland out of a total of 124,418 births, but in 1866 there were 11,673 out of 113,667. This marks a considerable improvement, and in fact during the twenty years 1879-88 there was a steady, although not a continuous decline in the rate. The rate for 1888—8.34 per cent.—was slightly higher than that of the previous year; that of 1889 was only 7.85. The following detailed figures are based on the returns for 1888. In the principal towns the rate was as follows: Glasgow, 8.3; Edinburgh, 8.5; Dundee, 10.3; Aberdeen, 10.3; Greenock, 5.3; Leith, 6.6; and Paisley, 6.3 illegitimates out of every 100 registered. The lowest proportion in urban Scotland was in Glasgow—landward and suburban district, 4.3. The highest rural proportion was in Wigtownshire, with 18.2; and the lowest rural proportion was in Kinrossshire, with 4. Next to Wigtownshire for illegitimacy came Banffshire, with 16.8; Kirkeudbright, with 15.7; Elginshire, with 15.2; Dumfriesshire, with 13.9; Aberdeenshire, with 13.2; Kincardineshire, with 12.4; Roxburghshire, with 11.2; and Berwickshire, with 11.1 per cent. The average is brought down by the low rates in the shires of Kinross, Ross and Cromarty, Dumbarton, Renfrew, Fife, Clackmannan, Stirling, Bute, Lanark, and Linlithgow, which range between 4 and 6.8 per cent. The other counties range about the average for all Scotland, with the exception of Shetland, which shows the comparatively low rate of only 4.8 illegitimates in every 100 births. In 1889 Shetland was the lowest country, with 4; Kinross having 6.7; Wigtown had 17.7 per cent. What is called the insular rural districts had an average of 6.2. The comparison

for 1888 may be otherwise summed up thus: 1 child in every 12 born throughout Scotland was illegitimate; but in the principal towns the proportion was 1 in 13; in the large towns, 1 in 15; in the small towns, 1 in 12; in the mainland rural districts, 1 in 10; and in the insular rural districts, 1 in 16. The tendency to illegitimacy in Scotland is greater in the north-eastern and southern rural districts than in the south-western mining and manufacturing districts—which is much the same distinction as we observed in England. Only, in no part of England are the figures so deplorable as in Scotland. Various theories have been advanced to account for this, but it is doubtful if the whole solution has yet been found. The following may at any rate be instanced as among the probable causes of the prevalence of illegitimacy in Scotland: a national caution, which deters from early and improvident marriages; the laxity of the marriage-laws in respect of the subsequent legitimation of children born out of wedlock; and the herding together of farm-labourers in bothies and farm-buildings. It is to be noted, also, that a large proportion of the illegitimacy can hardly be ascribed to vice, seeing that the parents often live together and rear their families just as if they were legally married, and as, perhaps, many of them will be some day. For this curious practice no doubt the former high proclamation fees may have been to some extent responsible.

In Ireland we find a very different state of affairs. There, in 1888, of 106,433 births registered only 3124 or 2.9 per cent. were illegitimate. Since 1884 the percentage has ranged between 2.7 and 2.9. This is the average for the whole island, but in Ulster the percentage was 4.4; in Leinster, 2.5; in Munster, 2.2; and in Connaught as low as 0.7. Dublin county was chargeable with nearly one-tenth, Londonderry county with about another tenth, and Antim with about one-fifth of the whole. The marriage-rate in Ireland is curiously low, being only 4.20 per 1000 of the population, as against 14.1 in England, and 12.4 in Scotland. Poverty may explain the low marriage-rate, and it is noticeable that of the 78,684 emigrants of that year over 80 per cent. were between fifteen and thirty-five years old—that is, of the marriageable age. The infrequency of bastardy can, however, only be ascribed to the chastity of the people, early marriage, and the wholesome restraints of the church.

To turn now to British colonies, we shall find some interesting figures; but it is important to bear in mind that birth-rates, like marriage rates, based upon a comparison with the total population, are somewhat misleading where the population is in an abnormal condition. As in most of the colonies the males largely exceed the females, there must necessarily be an abnormally small proportion of child-bearing women. In 1887 the illegitimate births in Victoria numbered 1580, or 1 in every 21 births registered. This rate shows a small increase since 1880, when the rate was 1 in 27. The mean for fifteen years was 4.25 per cent. of the total births, but the total for 1887 was 4.78 per cent. of the births. As regards the other Australasian colonies, illegitimacy is most rare in New South Wales, where it was (1886) 1.65; next in Queensland (1886), 3.97; next in Tasmania (1887), 3.40; and next in New Zealand (1886), 3.12 to every 100 children born. These figures are remarkably low, but then we must remember that the populations are not yet in a normal condition, and also that the statistics of illegitimacy for many reasons never reveal the whole truth.

This fact must be borne in mind in considering the following table of the proportion of illegitimacy in all the countries of the world for which

figures are available. The figures given are all for the period 1881-90.

	Year	Per cent of illegitimates to total births
England and Wales	1888	4.6
Scotland	1887	8.34
Ireland	1888	2.9
Austria (average)	1887	14.80
Carinthia		15.00
Lower Austria and Styria		25.00
Upper Austria		20.00
Dalmatia		3.50
Hungary		8.00
Belgium	1887	9.30
Denmark	1886	10.00
France	1887	8.20
Germany (average)	1886	9.47
Upper Bavaria		15.67
Schaumburg Lippe		2.74
Prussia		8.24
Alsace Lorraine		8.10
Greece	1889	1.60
Holland	1887	3.22
Italy	1887	7.45
Portugal (certain provinces only, returns incomplete)	1885	11.00
Roumania	1887	5.00
Russia (average 1867-81)		3.00
Spain	1884	5.40
Sweden	1886	14.88
Norway	1886	7.90
Switzerland	1887	4.80
Brazil (estimate)	1884	25.00
Canada		
Costa Rica	1886	24.00
Guatemala—Whites	1887	50.00
Indians	"	25.00
United States		
New South Wales	1886	1.65
Victoria	1887	4.78
Queensland	1886	3.97
South Australia, no statistics		
West Australia	1888	3.95
Tasmania	1887	3.40
New Zealand	1886	3.12

In the following table we show the comparative prevalence of illegitimacy in the principal foreign cities:

ILLEGITIMATE BIRTHS TO EVERY 1000 BORN.

Vienna	449	Leipzig	211	Ghent	144
Prague	429	Dresden	208	Hamburg	138
Munich	429	Milan	204	Frankfort	132
Stockholm	396	Rome	194	Turin	132
Moscow	390	Venice	181	Antwerp	129
Budapest	299	Breslau	186	Cologne	124
Copenhagen	279	Bucharest	175	Palermo	101
Paris	268	Liege	174	The Hague	99
St Petersburg	236	Christiana	162	Naples	86
Frieste	211	Berlin	154	Rotterdam	70

None of the above figures are presented as absolutely accurate. They can only be approximate in the best case, for in every country there must always be a large number of bastards who either are not registered at all, or who are registered as legitimate. But as far as they go the figures are instructive. They do not, however, enable one to form any conclusion as to the causes of illegitimacy in respect either of religion, of education, of industrial occupation, or of distribution of population. Neither can any theory be well evolved from a racial basis when we find Sweden with as high an average as Austria, and both with more than twice the average of Italy and Spain. It is a remarkable fact that in the year 1851 more than one half of the entire births in Vienna were

In the cases marked with an asterisk the percentage is of *avuncular* births; in the other cases, of total births registered, including still-born.

† No statistics are available for Canada.

‡ In the United States there seems no efficient system of registration of marriages and births, a fact upon which the Commissioner of Labour comments in his recent special report on "Marriage and Divorce" in the republic. Some of the individual states record the illegitimate births, but the figures are unshading because incomplete. Thus, the state of Indiana returned, in 1886, 38,370 legitimate and 500 illegitimate births, the illegitimate being only about 1.06 of the whole, a result which in the light of the above table we can only regard as due to defective registration.

illegitimate, but there is no explanation forthcoming of that fact, nor of the improvement revealed in the above table. In Europe generally, although not universally, there seems a tendency to decrease in the rate of illegitimacy; but how far that appearance may be due to moral causes or merely to more comprehensive statistics it is impossible to say.

In the periodical reports of the respective registrars-general will be found details referring to England, Scotland, and Ireland. The *Victorian Year-book*, by H. H. Hayter, government statistician, may be consulted for the Australasian colonies. The figures for foreign countries have been compiled from official and other sources too numerous to mention. Information about illegitimacy is given in the *Journal de la Société de Statistique de Paris* (24th and 26th years); in *Procedimientos del Departamento Nacional de Estadística, 1886* (Buenos Ayres, 1887); and in *Popolazione. Movimento dello Stato Civile e Condizioni Interazionali per gli anni 1865-83* (Rome, 1884). In the Journal of the Royal Statistical Society (London) for 1859 and 1862 there are interesting papers on the subject. See also A. Leffingwell's *Illegitimacy and the Influence of the Seasons on Conduct* (1892).

Illimani, one of the principal mountains of the Bolivian Andes, 10 miles SE. of La Paz. Height, 21,150 feet. See ANDES.

Illinois, the seventeenth in area of the United States, but the third in population, extends from Wisconsin and Lake Michigan on the N. and NE. to the junction of the Ohio and Mississippi rivers at the extreme SW. a distance of nearly 400 miles. It is bounded on the E. by the state of Indiana, from which it is partly separated by the Wabash River; on the S. it is separated from Kentucky by the Ohio; and on the W. the Mississippi flows between it and the states of Iowa and Missouri. The area is 56,650 sq. m., or nearly that of England and Wales.

The surface of Illinois is the most level of any state in the Union, except Delaware and Louisiana; and its wide grassy plains, though broken by numerous streams fringed with belts of fine timber, have gained for it the name of the Prairie State. The drainage is towards the south-west, through streams which flow into the Mississippi. The Illinois River, the largest in the state to which it gives name, is formed by the union of two streams in the north-east of the state, about 45 miles south-west of Lake Michigan, and has a south west course of about 500 miles in all, joining the Mississippi 20 miles above the mouth of the Missouri. The fertile soil—a heavy black loam with a favourable climate, makes this the richest agricultural state in the Union; and Illinois ranks first for the production of corn, cattle, hogs, and horses.

The annual value of the principal crops—maize, oats, hay, wheat, potatoes, rye, barley, buckwheat, flax, tobacco—is well over \$150,000,000. There are extensive vineyards in the state, and good wine is made. Much fruit is raised, especially for the markets of Chicago. Forests still cover a large area of the land. Honey and wax are obtained on a large scale. There are 1,500,000 horses and mules, over 3,000,000 cattle, and 1,000,000 sheep in the state.

The mineral output of Illinois, especially of bituminous coal, is also large; the state ranks next to Pennsylvania in this respect. Nearly a fifth of the entire coalfield of the United States is found in this state; and though some three-fourths of the coal is found in the Joliet region in the north-east, there are some 900 collieries in about fifty separate counties of the state. The annual output reaches 15,000,000 tons, and the industry employs 30,000 persons. There are brine-springs in the south of the state. Iron and zinc are also worked; and other

minerals are lead, limestone, salt, and fluor spar, the last found near Roseclare.

The position of Illinois presents unusual facilities for commerce. It has 400 miles of navigable rivers; a waterway to the Atlantic through the great lakes; and the drainage canal (1900) from the Chicago River to the Desplaines connects Chicago with the Mississippi River. Illinois has more railroads than any other state—10,776 miles in 1897. The trade of the state centres in Chicago, and in the article on that city statistics are given, as well as some indication of the leading manufactures. Of these last the principal are connected with agriculture.

The state is divided into 102 counties. The governor and most of the other state officers are elected for four years, the judges of the supreme court for nine. The legislature meets biennially; and to the lower house each district returns three members, cumulative voting being permitted in order to provide for the representation of minorities. Twenty representatives are sent to the Federal congress. The provisions for education are liberal. The state maintains two normal schools, an agricultural college, and an industrial university; and besides these there are many other colleges and universities. A compulsory educational law is in force, which requires children between the ages of seven and fourteen to attend for at least sixteen weeks in the year some public day school, or some private school teaching the branches commonly taught in the public schools. The most important educational institutions, including the magnificently endowed Chicago University, are in and about Chicago (q.v.). Thirty higher institutions have 700 teachers and over 10,000 pupils. Over 25,000 elementary teachers instruct 800,000 pupils. The state charitable institutions include four hospitals for the insane, at Elgin, Kankakee, Jacksonville, and Anna; an institution for the deaf and dumb, and another for the blind at Jacksonville; an asylum for the feeble-minded at Lincoln; a home for the orphans of soldiers at Normal; and eye and ear infirmary at Chicago; a reform school for boys at Pontiac; and a soldiers' and sailors' home at Quincy. The 475,000 Roman Catholics in the state have an archbishop and three bishops.

Formerly a part of the North-west Territory, Illinois was organised as a territory in 1809, and admitted as a state on 31 December 1818. While the Federal law at that date made a population of 40,000 a condition of admission, it is well established that the actual population of Illinois was then but 34,629. In 1830 the population numbered 137,445; in 1850, 851,470; in 1870, 2,539,891; in 1880, 3,077,871; and in 1890, 3,826,351. Chicago is by far the largest city of Illinois; its limits embrace more than a fourth of the entire population of the state. Peoria, Quincy, Springfield (the capital), and Rockford rank next in population. Important events in the history of Illinois have been the Indian wars of the territorial period, the Black Hawk war of 1832, and the Mormon (q.v.) troubles in 1840-44. The state raised six regiments for the Mexican war, and during the civil war contributed 259,092 men to the Union armies, of whom over 29,000 were killed in action or died of wounds or disease. At Springfield Abraham Lincoln lived before he was elected president, and there he is buried. See S. Breese, *Early History of Illinois* (Chicago, 1884); J. Moses, *Illinois, Historical and Statistical* (Chicago, 1889).

Illiterates, a term used to designate those persons who are unable to read or write, or both. The percentage of illiterates in a country furnishes one of the few means of estimating quantitatively the average level of intelligence, or at least of education, possessed by the people of that country.

Unfortunately a strict comparison cannot be made, because the statistics of illiteracy in different countries are not based upon one uniformly recognised method of obtaining them. (1) A few countries—e.g. the United States, Hungary, Italy, and Portugal, and the Australian colonies of Victoria and Tasmania—have endeavoured to take an exact census of illiterates; in their enumerations all children below six years of age were excluded, except in the United States, which excluded all children below ten years of age.

United States (1880) 22·15 per cent. Hungary (1880) 37·14 per cent.
Italy (1881) 54·30 " Portugal (1878) 79·07 "

The high percentage of the United States is due to the low educational status of the Negro population. In 1881 there were in the colony of Victoria 23·80 per cent. of illiterates, and in Tasmania 43·78 per cent. Of the other methods that are employed to ascertain the number of illiterates (2) the most complete results are afforded by the enumeration of the men and women who, on the occasion of their marriage, are unable to sign their names in the registers. On this basis we have the following results for comparison in the year 1886

Country.	Men.	Women.	Per cent.
England and Wales.	9·60	11·50	10·55
Scotland.	4·65	8·28	6·46
Ireland.	23·40	25·50	24·45
Victoria.	2·00	1·98	1·99
New South Wales.	3·76	4·20	3·98
Queensland.	4·52	6·71	5·62
South Australia.	3·04	3·49	3·26
New Zealand.	1·92	2·89	2·40
Prussia (1884)	5·31	5·11	4·21
France (1882)	14·59	22·62	18·50
Italy (1887)	42·36	62·80	52·58

It may be stated that while in England and Wales, in 1863, 23·8 per cent. men and 33·1 per cent. women signed their marriage register by mark, in 1897 the figures were only 3·3 per cent. men and 4·9 per cent. women. In Scotland in 1897 the proportion was 2·16 per cent. men and 3·27 per cent. women, while in several counties all signed their names. In Ireland, in the same year, the proportions were 15·1 per cent. men and 13·2 per cent. women. (3) The subjoined table gives the number of recruits who were unable to read and write in the respective countries named, and where universal conscription is in force:

Belgium (1884)	0·02	Holland (1887)	8·5
Württemberg (1884)	0·02	France (1886)	10·50
Bavaria (1884)	0·08	Belgium (1887)	13·87
Saxony (1884)	0·15	Austria (1885)	25·09
Sweden (1883)	0·27	Hungary (1885)	38·60
Denmark (1884)	0·36	Italy (1885)	129·8
Germany (1884)	1·27	Russia (1882)	78·79
Switzerland (1885)	1·3	Serbia (1884)	75·61
Prussia (1884)	1·97		

(4) At the general election of 1886 in Great Britain and Ireland there voted in England and Wales 38,587 illiterate persons, in Scotland 4836, in Ireland 36,722, giving a percentage of 2·60 out of a total of 2,969,381 voters who went to the poll. (5) Out of a total of 31,473 persons of all ages arrested in the colony of Victoria, in the year 1887, 26,509 could only read or write imperfectly, and 3333 were totally unable to read, a percentage of 86·56 illiterates apprehended. Illiteracy among voters, both white and black, increased enormously in the south of the United States between 1870 and 1880. In Texas in 1870 there were 17,500 illiterate voters; in 1880 there were 33,085. But between 1880 and 1890 the illiteracy in the States was reduced to 13·1 per cent. of the total population. People unable to sign their name attest a document by making a cross, certified by a witness who can write.

Illorin. See ILORI.

Illuminati (Lat. 'the enlightened'), a name assumed by or conferred upon various mystics professing to have special knowledge of God and things

divine. The sects which may be included under the title are the *Alumbrados*, who originated in Spain about 1520, and were finally crushed by the Inquisition; the *Guarriors* in France, who flourished from 1623 to 1635; another sect which arose in the south of France about 1722, and perished in the storms of the Revolution; an association of mystics in Belgium, in the later half of the 18th century. But the name is more particularly given to the Order of the Illuminati, founded at Ingolstadt on May 1, 1776, which soon spread over almost all the Catholic parts of Germany. Its founder, Adam Weishaupt (1748-1830), professor of Canon Law at Ingolstadt, at first called it the Order of the Perfectibilists. Filled with detestation of Jesuitism, and impatient of the restraints which were at that time imposed on the freedom of human thought in Catholic Germany, especially in Bavaria, Weishaupt set himself to combat ignorance, superstition, and tyranny, by founding an association which should be a luminous centre for the promotion of rational and religious enlightenment. Religious dogmas and forms of worship were rejected; his religious system was a form of deism. But the society prosecuted political aims as well, in that the members of the highest of the orders into which it was divided were pledged to the furtherance of Republican opinions. Implicit obedience to the chiefs of the association was one of the first laws of its constitution. The accession of Baron von Knigge to the new order, and the support which it received from the Freemasons, led to its rapid extension; about 1780 it counted more than 2000 adherents, mostly men of rank and influence. It was regarded with favour by Goethe, Herder, Nicolai, Ernest H. of Gotha, and Karl August of Weimar. Weishaupt and Knigge quarrelled in 1784. The order began to be openly denounced as dangerous, in 1784 and 1785 edicts were issued by the Elector of Bavaria for its suppression, and Weishaupt was degraded and banished. See his *Geschichte der Verfolgung der Illuminaten* (1787) and *Kurze Rechtfertigung meiner Absichten* (1787).—*Illuminism*, the system of the French illuminati, is sometimes used as a synonym for Freemasonry and unbelief, from a Catholic point of view.

Illumination of Manuscripts, the art of painting manuscripts with miniatures and ornaments, an art of the most remote antiquity. The Egyptian papyri containing portions of the Ritual or 'Book of the Dead' are ornamented with veritable drawings and coloured pictures. Except these papyri, no other manuscripts of antiquity were, strictly speaking, illuminated; such Greek and Roman manuscripts of the 1st century as have reached the present day being written only. Pliny, indeed, mentions from Varro that authors had their portraits painted on their works, and refers to a biographical work, with numerous portraits introduced, but all such have disappeared in the wreck of ages; the oldest illuminated MSS. which have survived being the *Dioscorides* of Vienna and the *Psalm* of the Vatican, both of the 4th century, and ornamented with vignettes or pictures in the Byzantine style of art. St Jerome, indeed, in the same century, complains of the abuse of the practice, as shown by filling up books with capital letters of preposterous size. The Byzantine style strongly influenced every other early style throughout the West, and its influence can be traced as late as the 14th century.

The art of illuminating manuscripts with gold and silver letters is supposed to have been derived from Egypt, but it is remarkable that no papyrus has any gold or silver introduced into it. The artists who painted in gold, called *Chrysographi*,

are mentioned as early as the 2d century. One of the oldest manuscripts of this style is the *Codex Argenteus* of Uffilas (360 A.D.); and the charter of foundation of Newminster at Winchester by King Edgar (966 A.D.), six centuries later, shows the use of these letters. Gold letters seem to have been used in the East during the 12th and 13th centuries. At an early period the use of illuminated or decorated initial letters commenced to be distinguished from the illuminated or painted pages placed at the head of Byzantine manuscripts. Originally they were not larger than the text, or more coloured; but the Syriac manuscripts of the 7th century have them with a pattern or border; and they go on increasing in size and splendour from the 8th to the 11th century, when large initial letters, sometimes decorated with little pictures or miniatures, came into fashion in the Greek and Latin manuscripts. The subjects of the figures mixed up with the arabesque ornaments often referred to the texts; warriors and warlike groups of figures being introduced when the text referred to war, symbolical representations of hell where the chapters following treated on that region. These initial letters soon increased to a great size, being from 2 to 24 inches long; they were most used in the 8th and 9th centuries, but continued till the 12th century, and degenerated in the 16th to the last decadence of art—the grotesque. In the 13th century burnished gold was used as a background for letters and miniatures, and so finely were these backgrounds executed that they appear like plates of solid gold. The art which flourished in the eastern and western empires passed over to Ireland, and there gave rise to a separate school or kind of illumination. This style, which consists in a regular series of interlaced ribbon ornaments, often terminating in the heads of gryphons and other animals, seems to have been derived from the later patterns of Byzantine art, seen on mosaics, mural paintings, and other objects. This Celtic style is finely exhibited in the remarkable MS. at Trinity College, Dublin, known as the 'Book of Kells,' which is believed to be of the 9th century. The minute size and number of the interlacements is quite wonderful.

The Hiberno-Saxon style is seen in the so-called Durham Book in the British Museum (Cott. MS. Nero D. IV.), which is only second to the Book of Kells in beauty. It was written by Eadfrith, Bishop of Lindisfarne (died 721), in honour of St Cuthbert. The various schools of art in the middle ages found their homes in the different monasteries, and the so-called *Opus Anglicanum* is exhibited in the Benedictinal now in the possession of the Duke of Devonshire at Chatsworth. This was produced at the Old Minster at Winchester, and was executed by Godemann (afterwards abbot of Thorney) for Ethelwold, Bishop of Winchester (963-984).

In the 12th century a new style arose which was distinguished by the profusion of its ornamentation, intricate modes of illumination, and abundant use of gold and silver. In the 13th century the art still more deteriorated in western Europe, but the manuscripts of the 14th century show a great advance in painting over the works of previous centuries. Dante's *Divina Commedia* in the British Museum (Egerton MS. 963) is a fine specimen of the work of Italian artists in this century. The Arundel Psalter, also in the British Museum (Arundel MS. 83), is a noble work of English artists. It was given by Robert de Lyle to his daughter Andry in 1339.

In the 15th century the art of miniature began to decline in England, and the finest works were produced by foreign painters. This is the case

with the famous Bedford Missal in the British Museum. It was prepared for John, Duke of Bedford, son of Henry IV. and Regent of France, on his marriage in 1423 with the daughter of John, Duke of Burgundy. The duchess presented the MS. (with her husband's consent) to Henry VI. on Christmas Eve, 1430. In this same century were produced the celebrated choir books in the cathedral of Siena, by Girolamo da Cremona and Liberale da Verona, who were paid for their work in 1468 and 1472-73. One of the most beautiful specimens of the work of the next century is the Book of Hours of Anne of Brittany, wife of Louis XII., which has borders of natural plants on a gold ground. The artist to whom we are indebted for this priceless monument of French art at the period of the Renaissance was Jean Bourdichon (1457-1521).

The usual mode of production adopted in the Scriptorium was for the scribe to rule a space for his text in accordance with the general design, and to write within these limits. He was followed by the illuminator of initials, borders, and ornamental accessories. Then came the miniaturist. St David, the patron saint of Wales, is said to have been an assiduous illuminator, and among the most celebrated miniaturists may be mentioned Giotto (1276-1337), Fra Angelico (1389-1455), Attavante (1455-1520), Julio Clovio (1498-1578), Vincenzo Raimondo (died 1557), and Boccardino (16th century). Raphael and Jan van Eyck might be added to the list. That splendid example of Flemish illumination, the Franciscan Breviary of Cardinal Domenico Grimani (1461-1523), has been attributed to Memling, but later inquiries have proved that he had nothing to do with it.

In the reign of Louis XIV. the art became extinct, ending with a style of painting called *encreux gris*, a kind of monochrome, in which the lights are white or gold, and shaded so as to emulate bas-reliefs. Among oriental nations the Persians, Hindus, and Chinese have illuminated manuscripts of great beauty, none of which, however, can compete with those of the western nations in antiquity. For beauty of design some of the Arab manuscripts are charming, but their antiquity does not reach beyond the 13th century. The Chinese Buddhists have also illuminated classics, or religious books of their sect, one of which, the *Diamond Book*, as it is called, in the British Museum, has a text splendidly printed in silver and gold letters on a blue ground, and the vignettes charmingly painted in tempera, on macerated leaves of the *Ficus Indica*.

Audsley, *Guide to Illuminating and Missal Painting* (1861); De Gray Birch & Jenner, *Early Decorative and Illuminations* (1879); J. H. Middleton, *Illuminated Manuscripts* (1892); Falconer Madan, *Books in Manuscript* (1893).

Illuminations. See PYROTECHNY.

Illusions are usually distinguished, as having some basis in outward physical facts, from *delusions*, which are purely subjective hallucinations, with no foundation save perverted imagination, or otherwise disordered faculties. Optical illusions are exemplified by the appearances connected with mirage. See OPTICAL ILLUSIONS, APPARITIONS, DREAMS, HALLUCINATIONS, INSANITY; and Sully's *Illusions* (Inter. Sc. Series, 1881).

Illustration of Books. Since man first discovered how to convey his thoughts to others by means of writing, he seems to have felt the want of some method of illustration or embellishment. From the Egyptian papyrus down to the invention of printing this was supplied by pictures,

coloured or uncoloured, engravings, carvings, &c., executed by hand, and so far as these have any connection with books or writings their history will be found in the article ILLUSTRATION OF MANUSCRIPTS. The first printed books were entirely illustrations, both pictures and text being printed from blocks engraved on wood in relief, such as the *Biblia Pauperum* (q.v.), and many others. The *Ars Memorandi* (end of 15th century) comprised fifteen New Testament pictures, faced by the same number of text pages, all engraved on wood. The Mazarin Bible (1455), the first book completely printed from movable types, many of the copies of which were beautifully embellished by hand, was sold as a manuscript, till the number of copies aroused suspicion. Many other spurious MSS. were produced in the same way, the larger price obtained for them forming a temptation to those having the secret of printing.

The first edition of the *Speculum Humanae Salvationis*, said to have been printed by Coster about 1440, is supposed to be the first book in which two different coloured inks were used on the same page; and the ornamental capitals in the Psalter of Pust and Schöffer in 1457 are beautiful specimens of printing in two colours. Probably the first printed book with wood-engraved illustrations used throughout the text was the *Fables of Ulrich Bolmer*, issued by Albert Pfister, printer of Bamberg, in 1461, which had 101 engravings on wood. In Italy the first known example is the *Meditationes*, published by Ulrich Halm, a German, in Rome, 1467, of which three copies are still known to exist. The most artistic book of this period was certainly a volume on military art by Valturinus, illustrated by eighty-two designs by Matteo Pasti, at Verona, in 1472. The designs are in outline and very cleverly drawn, though poorly engraved.

The invention of the method of printing from engraved (intaglio) plates introduced a new factor into book illustration. *Il Monte Santo di Dio* (Florence, 1477) was the first book issued with illustrations engraved on metal.

In the beginning of the 16th century many books were beautifully illustrated by pictures in chiaroscuro, produced by three or four blocks, engraved on wood, printing different shades of the same colour, generally ochre, brown, gray, or red, many of the original drawings being by Titian, Raphael, Parmigiano, and other masters. About the middle of the 16th century engraved plates began to be used in conjunction with wood-engravings in the same books; and from this period a struggle for supremacy began between the two arts, which finally resulted in favour of metal at the end of the century. Wood-engraving declined till revived by Bewick, and metal-engraving and etching had the field to themselves. During the 18th century many books were beautifully illustrated by engraved and etched title pages, vignettes, and tailpieces, the most celebrated artists making designs for the purpose; the type was first printed, leaving spaces on which the plates were afterwards printed. The lead taken by France in the 18th century was closely followed by Germany and England. Coloured illustrations, when not coloured by hand, as they generally were, were printed by means of numerous carefully prepared wood blocks, each printing a different colour. An elaborate account of the method will be found in Savage's work. In short, the history of book illustration reflects more or less faithfully the state of art of the period, and it may be traced in the articles, Book, Engraving, Wood engraving, Bartolozzi, Bewick, Caxton, Durer, Hogarth, Turner, &c.

The invention of lithography in 1796 introduced a third element, which was immediately taken

advantage of. Being much cheaper than steel-engraving, it gradually tended to supersede that process for book purposes, its special adaptability for coloured work giving it great advantages over its rival. In England book illustration may be said to have reached its culminating point as regards engraved and etched plates in the first half of the 19th century, in the series of annuals, keepsakes, and the higher-class books illustrated by such masters as Stothard, Turner, &c. The revival of wood-engraving by Bewick and his pupils gradually led to the restoration of that art as an illustrating medium. In this it was greatly aided by the facility with which wood engravings can be printed along with the text, together with the advance made in typographic printing. The series of Christmas books illustrated by John (afterwards Sir John) Gilbert and Birket Foster had no small share in that advancement. Among the artists who have helped to raise the art to its present high position may be mentioned Cruikshank, H. K. Browne (Phiz), Doyle, Leech, Tenniel, Millais, F. Walker, W. J. Linton, Herkomer, &c. The development of what has been called the American school of wood-engraving has still further increased the influence of that branch of art for illustrative purposes.

Relief-block Processes for Book Illustration.—While Photogravure (q.v.) threatens the final extinction of steel-engraving, very many processes have been invented to produce relief blocks with a view to supersede wood-engraving in book illustration. The object aimed at is to reproduce drawings in line or wash, in fac-simile, on a relief block capable of being printed from the surface at the type press. That is, the lines or parts which impress the paper are to be left in relief, while the white parts are cut out so as to leave the paper unprinted.

What are called 'process' relief blocks may be divided into two kinds—those reproduced from black-and-white, or line drawings by pen and ink, and those from half-tone photographs or wash drawings. The former, as being the simpler, we shall describe first.

The simplest form of it is when a drawing is made in transfer ink on lithographic transfer paper (see LITHOGRAPHY), or when a proof of a line drawing on stone or line engraving can be got in transfer ink. This transfer drawing or proof is transferred to the polished surface of a zinc plate in the ordinary lithographic manner. Zinc is generally used, because it is cheap, and is readily soluble in etching acid; but copper is sometimes used for very fine work. After the transfer the plate is wetted, and the lines are inked repeatedly till a thick coating of ink covers the lines of the drawing. Powdered asphalt, or other similar substance, is then dusted over the plate, which is gently heated till the asphalt is incorporated with the ink. The back of the plate and the other parts not requiring to be etched are covered by varnish, and the plate is put into a bath of acid for the uncovered parts to be etched away, leaving the lines in relief. As the etching, if carried on continuously, would undermine the lines and finally cut them off altogether, the plate is removed from the bath after a very slight etching. It is then washed and gently heated, which causes the asphalt and ink to run down the side of the lines already in relief, and protect them from further etching. This is a very delicate part of the process, and great skill is required to let the protecting compound run down enough and no more. The plate is returned to the bath and etched a little more. The washing and heating is repeated, and so the etching and heating goes on gradually till a sufficient depth is obtained

for the fine parts. During the etching a rocking motion is given to the bath to make the acid act more equally and allow the bubbles of gas to escape. The larger white parts are generally cut deeper afterwards with machine drills.

When other than transfers are to be reproduced, such as pen-and-ink drawings, engravings, or any other drawing in line, the subject is photographed to the required size. Here this process has a decided advantage over that just described, inasmuch as the drawing to be copied may be made of any convenient size, while a drawing on transfer paper must be of the exact size required. The photograph being obtained, it is treated as for a photolithograph (see LITHOGRAPHY), transferred to stone, and a re-transfer taken to put on the zinc, which is then treated as already described. By this process a little of the sharpness of the drawing is lost by the repeated transfers, every one tending to thicken and blur the lines a little; a more direct method of putting the drawing on the zinc is as follows. The plate is thinly and evenly coated with bitumen, bichromatised albumen, or other substance sensitive to the action of light. A very strong photographic negative, taken in reverse from the drawing, in which the lines are clear glass and the lights as dense as possible, is put on the plate and exposed to the light. The light acting through the lines on the negative render the corresponding parts of the coating on the zinc, to a sufficient extent, insoluble, while the light parts, being protected by the negative, can be dissolved out by a suitable solvent in the case of bitumen, or washed off if the albumen method is used. The drawing is thus left on the zinc in bitumen, and, as that substance is a good protective against acid, the plate is etched as already described.

There are also several gelatine processes, one or two of which may be shortly described. In the *swelled gelatine* process a plate of glass, coated with a film of bichromatised gelatine, is exposed under a negative, from a line drawing, and afterwards soaked in cold water, when the parts not acted upon by the light will swell up sufficiently to allow of a cast being taken which will give the lines in relief, or, if the plate be put in *hot* water, will be removed altogether, leaving the lines in relief. Or, if a photo-*positive* be put on the film, the lines will be left soluble and may be dissolved out by hot, or swelled up by cold water. In these gelatine processes, however, the relief is very low, and the white parts have to be made up with heated wax by hand, which is a very delicate process, or cut away in a subsequent stereotype. In some methods a solid slab of prepared gelatine is used, when the etching or dissolving out may be made as deep as required.

There are an infinity of other slightly differing processes for producing the same result, but as they are all more or less founded on the same principle, they do not call for separate description.

The production of relief blocks from ordinary photographs or drawings made by washes of black and white is a much more delicate matter. Intaglio plates have indeed been in successful use for many years (see PHOTOGRAVURE), but relief blocks until the invention of Meisenbach's process baffled all efforts. As in relief block every part which touches the paper prints *black*, and every part which does not touch the paper leaves it *white*, it is obvious that until some method was devised of turning the smoothly graded tones of a photograph into something which could be represented in pure black and white, success was impossible.

The method sought after was to break up the photo-tones into some sort of grain, stipple or line,

which should be closest in the darkest parts, and become more open as the lights were approached. It would be unadvisable, even if it were possible, to enumerate all the devices which have been invented and patented for this purpose. That patented by Meisenbach of Munich in 1882, however, as the one on which nearly all the most successful subsequent processes are based, may be briefly explained. A glass plate is prepared with fine parallel lines, thus . This is exposed between the lens and the sensitive plate in the camera, at a very short distance from the plate, and when the exposure is half completed the cap is put on the lens, the lined plate is taken out and put in with the lines in the reverse direction, thus , and the exposure is completed. The resultant negative is thus broken into minute regular dots. These 'screens' are now prepared with cross lines, thus avoiding the necessity of changing the position during exposure. They are glass plates with etched lines, or are photographically printed from a plate so prepared—two plates being fastened face to face with their lines in opposite directions to give the cross effect. The lines may vary in width from 85 per inch for newspaper printing, to about 150 per inch for fine printing. Plates with 200 per inch produce work so very fine in grain that special printing is required.

A *grained* photograph being finally obtained by means of any of the thousand-and-one processes, it is transferred to zinc and etched as described for the line process.

In addition to these photo-chemical processes, there are several mechanical methods of producing relief blocks, of which Messrs Dawson's Typo-etching process, an improvement upon Palmer's Glyphographic process (patented in 1848), is very extensively used for the production of maps, plans, diagrams, &c. A polished brass plate is covered with a film of prepared wax, on which the lines are drawn with special etching needles which clear away the wax down to the metal. Letters and words are stamped through the wax with types of varying sizes as may be required. The wax, which is of course very thin, is added to by melting other wax over the surface with a heated pointed metal tool. This stream of melted wax is skilfully prevented from running into the lines or letters, and when thick enough to give sufficient depth to the finished block, an electrotype is taken from the plate, in which the cleared surface of the brass forms the raised lines, and the built-up wax the sunk or white parts. This electrotype is the printing block. Many of the text maps in the present work are executed by this process: those in Vol. VI. p. 701, and Vol. VII. p. 762, are good examples.

Many other mechanical methods are used in engraving and etching, but generally they are too technical to be detailed here, and we have described nearly all which are of any public consequence.

It is obvious that these various processes, though simple enough in theory, give great scope for skill in manipulation, and much of their success depends on the ability of the operator. As a means of illustrating books they are making rapid strides towards complete success within the bounds, not by any means unlimited, of their capabilities. The rapidity with which they can be produced has rendered the daily illustrated paper a possible and accomplished fact. As to cost, blocks can be produced for from 4d. to 1s. 6d. per square inch of surface, according to the nature of the drawings, the stipple process being the more expensive.

The first and most important requisite is to obtain drawings suitable for the purpose, and these should be made by artists who have studied the capabilities and requirements of the various methods,

For the line processes the drawings, when not executed on transfer paper, should be made on bristol board or smooth-surfaced white paper, with some dense black pigment, as much of the success depends on the sharpness and blackness of even the faintest lines. Stephen's ebony stain, Winsor & Newton's liquid lampblack, and other pigments have been used for the purpose. The drawings should be larger than the required reproduction, as the reduction tends to refine the block, and care should be taken to see that every detail is exactly as wanted, for the process reproduces the defects as strongly as the beauties of a drawing. Given proper drawings and subjects suitable for the purpose, this process undoubtedly is capable of producing first-class work.

The stipple or Meisenbach process is a much more delicate affair, and from the care with which its blocks require to be printed, on account of the necessarily shallow nature of the etching, its application is much more limited. If nature photographs are reproduced on too small a scale, the stipple, if coarse, obliterates much of the detail, and, if too fine, is apt to blur in printing. But when drawings are specially made for it by artists who understand its requirements, it is capable of very fine results, and the drawing is reproduced with a fidelity seldom seen in an engraving. The drawings may be executed in lampblack and Chinese white, or any pure monochrome.

This process has been so improved and developed that it has become almost the universal medium for ordinary book illustration.

The weak point of nearly all tone-process work is that the sharpness and brilliancy of the original drawing gets softened and generalised away, and the result is sometimes flat and spiritless, with a tendency to become monotonous. The process has no *white*; even the highest lights are covered with tint. This difficulty is met by an increasing use of hand engraving on the blocks, in order to restore the vigour of the drawing, and to give something more or less like a good wood engraving.

The latest development of the process is the *Three-Colour Process*. Coloured pictures, or naturally coloured objects, are by this method reproduced and printed by means of three blocks, printed with red, yellow, and blue inks respectively. It is founded on a suggestion by the late Clerk Maxwell, and Professor Vogel of Berlin and many others have helped in its development. By means of coloured screens, or *light-filters*, three separate negatives of the subject are taken, reproducing the colour values of the yellow, red, and blue rays respectively. These negatives are by the usual process made into blocks, which, if properly printed with the correctly coloured inks, produce a more or less exact facsimile of the original object or drawing. Many very fine examples of the process have been produced, in which every touch of the brush in a water-colour drawing has been faithfully reproduced. The care and delicacy necessary for successful printing, however, is very great, and the method should be limited to cases where specially prepared paper can be used in printing, or the result may be disappointing.

For purely photographic methods of illustration, such as colotype, see PHOTOGRAPHY.

Illyria (Lat. *Illyricum*), in ancient times the country that stretched along the eastern side of the Adriatic Sea, from Epirus northwards. It was not a homogeneous territory, but varied in extent at different periods of its history. The region was inhabited by numerous tribes, who seem seldom to have been held together by any sort of political cohesion. From some cause or other—probably the mountainous character of the region they inhabited was the principal cause—they were the last of the peoples of the Balkan peninsula to be brought within the fold of civilisation. The single Greek colony of Dyrrhachium or Epidamnus, in the south, was the only point whence the rays of Greek enlightenment could penetrate the darkness of Illyrian barbarism. The Illyrians are described as resembling the savage Thracians in their manners, as tattooing their bodies, as offering human sacrifices to their deities, but as honouring women, who even held chieftainships amongst them. For many years they seem to have kept up a series of incessant attacks upon the early kings of Macedonia; they levied tribute from Amyntas II., and slew Perdiccas (359 B.C.). But they were subdued by Philip II. and Alexander, who annexed their country to Macedonia. In the 3d century, after the breaking up of the Macedonian monarchy, they caused much annoyance to Greece and Italy by their piratical excursions. At length the patience of Rome was exhausted, and in two short wars (229 and 219 B.C.) she succeeded in subjugating the refractory Illyrians. Fifty years later they provoked a third war with Rome, which resulted in their defeat and the incorporation of their territories in the all-victorious republic. Nevertheless, the Illyrians only consented to be civilised at the sword's point, they frequently rose in revolt against their conquerors; but in 35 B.C. Illyria was made a Roman province. During the empire they served faithfully in the Roman armies, and even gave half-a-dozen emperors to the state, as Claudius II., Aurelian, Diocletian, Probus, and some others. Under the rule of the emperors the political importance of Illyria, or Illyricum, as the Romans called it, was greatly increased. In the 2d century Illyria extended as far north as the Danube, and even beyond it, and included Noricum, Pannonia, Moesia, Thraee, and Dacia. Constantine still further enlarged its boundaries, and made it one of the four chief divisions of his empire. But when the empire was divided between East and West, Illyria was also divided, Noricum, Pannonia, Moesia, &c. were designated as Illyris Barbara, and incorporated with the empire of the West; Illyris Græca, embracing Greece, Macedonia, Epirus, &c., was attached to the eastern empire. In the period of the final dissolution of the western empire Illyria was successively overrun by the Goths, the Huns, and several Slavic tribes, and nearly all traces of civilisation disappeared. The Illyrians themselves partly amalgamated with the Huns and their Slavic conquerors, and partly were driven southwards, where one of their tribes, the Albani, survive, at all events in name, in the modern Albanians. As the several Slavic states became consolidated and rose to power, the political importance of Illyria, and even its name, gradually died away. The name was revived in quite modern times, when Napoleon, in 1809, turned the territories he had wrested from Austria into the Illyrian provinces. In 1816, when they were restored to Austria, this power constituted out of them and the provinces of Carinthia, Carniola, Gorz, Gradisca, and Istria the kingdom of Illyria. But the designation was dropped in 1849, and the territories included in it were reorganised as provinces.

The geographical features of Illyria are described under BOSNIA, DALMATIA, MONTENEGRO, &c., the modern states or provinces with which it most nearly coincided.

The name Illyrian is also used in three other significations. In the 17th and 18th centuries it was used to indicate those Slavs who were members of the non-united Greek Church—i.e. principally the Servians or Razans. In the 19th century the terms Illyrian and Illyrian peoples were used in connection with the idea of the union of the Southern Slavs—the Servians, Croats, and Slovenians—into a revived Illyrian kingdom, an idea which seems to have been first made current by Gaj about 1835. Illyrian literature is sometimes used when Servian literature is meant; and Servian literature in this sense includes Dalmatian or Ragusan literature. See SERBIA, and RAGUSA. The scene of Shakespeare's *Twelfth Night* is laid in Illyria.

Imen (formerly *Mosk*), a lake in the Russian government of Novgorod, with an area of 354 sq. m., and a depth varying from 7 to 30 feet. The rivers Shelon, Lovat, Msta, and several others flow into the lake, which discharges its waters through the river Volkhof into Lake Ladoga. The lake abounds in fish.

Ilminster, an ancient market-town of Somersetshire, is situated on the Isle, 11 miles SE. of Taunton by rail. The church is a noble example of Perpendicular architecture. Some manufactures of ropes, bricks, and tiles are carried on. Pop. of parish (1831) 2957; (1891) 3135.

Il Obeid. See OBEID.

Ilori, or ILLORIN, capital of a Yoruba state in western Africa, and a great commercial centre, stands at an elevation of 1300 feet, about 160 miles NNE. from Lagos (on the coast). The people, 70,000 in number, consist of Yorubas, Hausas, Fulah, and others, and make cloth, arms, and leather. The state is now practically a province of the empire of Sokoto (q.v.); and is within the territory of the British Royal Niger Company. The religion is Mohammedanism, with strong traces of heathenism.

Ilsey, EAST, or MARKET HULSEY, a market-town of Berkshire, situated amid bleak and dreary downs, 9 miles N. of Newbury and 6½ S. of Didcot. Its sheep-markets count among the most important in the kingdom. Pop. 577. Archbishop de Dominis was rector of West Ilsey, 2 miles north-west. Pop. 377.

Image. See LENSES, MIRROR.

Image-worship (Gr. *εἰκονολατρεία*), the use in public or private worship of graven or painted representations of sacred persons or things, and especially the exhibition of honour, reverence, or worship to or towards such representations. Neither in the New Testament nor in any genuine writings of the first age of Christianity can any trace be discovered of the use of statues or pictures in the worship of Christians, whether public or private. The earliest allusion to such representations is found in Tertullian, who appeals to the image of the Good Shepherd as engraved upon the chalices. A very curious pagan caricature of Christianity of the same age, lately discovered scratched upon the wall of a room in the palace of the Cæsars (see GRAFFETTI), which rudely represents a man standing in the attitude of prayer, with outstretched hand, before a grotesque caricature of the crucifixion, and which bears the title 'Alexamenus worships God,' has been recently alleged by Catholics as an additional indication of at least a certain use of images among the Christians of the 2d century. The tombs of the Christians in the

Roman catacombs, many of which are of a date anterior to Constantine, frequently have graven upon them representations of the Dove, of the Cross, of the symbolical Fish, of the Ship, of Adam and Eve, of Moses striking the rock, of Jonah, of Daniel in the lions' den, of the apostles Peter and Paul, and above all, of the Good Shepherd; and those compartments of the catacombs which were used as chapels are often profusely decorated with sacred representations, the age of which, however, it is not easy to determine with accuracy. It is admitted by Catholics, however, that, from the fear of perpetuating idolatrous notions, for the first three centuries the use of images was rare and exceptional; nor was it until after the establishment of Christianity under Constantine, and particularly after the condemnation of the Nestorian heresy in 430, that statues and pictures of our Lord, of the Virgin Mary, and the Saints, were commonly introduced in churches, especially in the East and in Italy. And yet even in the 5th century the practice had already reached a great height, as we learn from the church historian, Theodoret, for the East, and from Paulinus of Nola, for Italy; and in the 6th and 7th centuries many popular practices prevailed which called forth the condemnation of learned and pious bishops both in the East and in the West. It was usual not only to keep lights and burn incense before the images, to kiss them reverently, and to kneel down and pray before them, but some went so far as to make the images serve as godfathers and godmothers in baptism, and even to mingle the dust or the colouring matter scraped from the images with the eucharistic elements in the Holy Communion! This use of images by Christians was alleged as an obstacle to the conversion of the Jews, and as one of the causes of the progress of Mohammedanism in the East; and the excesses described above provoked the reaction of Iconoclasm (q.v.). In the second Council of Nice (787) the doctrine as to the worship of images was carefully laid down. A distinction was drawn between the supreme worship of adoration, which is called *latreia*, and the inferior worship of honour or reverence, called *douleia*. The second Council of Nice declared that the worship to be paid to images is not the supreme worship of *latreia*, but only the inferior worship of *douleia*; and also that it is not *absolute*, and is not rendered to the images themselves, but *relative*—i.e. only addressed through them, or by occasion of them, to the original which they represent. A strange error in the translation of the Greek acts of the Council of Nice, by which it appeared that the same adoration was decreed by that council to images which is rendered to the Holy Trinity itself, led to a vehement agitation in France and Germany under Charlemagne, and to a condemnation by a synod at Frankfort of the doctrines of the Council of Nice. But an explanation of this error, and of the false translation on which it was based, was immediately afterwards given by the pope; and eventually the Nicene exposition of the doctrine was universally accepted in the Western as well as in the Eastern Church.

At the Reformation the reforming party generally repented the use of images as an unscriptural novelty, and stigmatised the Catholic practice as superstitions and even idolatrous. The Zwinglian, and subsequently the Calvinistic churches entirely repudiated all use of images for the purposes of worship. Luther, on the contrary, while he condemned the Roman worship of images, regarded the simple use of them even in the church for the purpose of instruction and as incentives to faith and to devotion as one of those *anaphoric*, or *adjuvant* things, which may be permitted, although not of necessary institution; hence, in the

Lutheran churches of Germany and the northern kingdoms, pictures, crucifixes, and other religious symbols are still freely retained. In many of the parish churches of England these remained till long after the Reformation. Thus, we find that William Dowling found ample employment during ten months of 1644 in destroying pictures and images in the churches of the single county of Suffolk, in accordance with an ordinance of parliament. In the modern Anglican Church the practice is still a subject of controversy, and the magnificent sculptured reredos erected in St Paul's Cathedral was protested against as idolatrous by some of the London clergy in 1888. In the Presbyterian Church and in all the other Protestant communions images are entirely unknown, although figures of patron saints and eminent churchmen have occasionally been set up, as in the restored St Giles' High Kirk in Edinburgh.

The Roman Catholic Church, through the decree of the Council of Trent, disclaims the imputation commonly made against Catholics of the idolatrous worship of images, 'as though a divinity dwelt in them, or as though we [Catholics] asked anything of them, or trusted in them, as the heathens did in their idols.' It renews the Nicene distinction between *absolute* and *relative* worship; the latter of which alone 'whereby we worship Christ and the saints, who are the prototypes of these images'—it sanctions or permits; and it contends for the great advantage, especially in the case of rude and unlearned people, to be drawn from the use of pictures and statues in the churches as 'memorials of the sufferings and of the mercy of our Lord, as instructive records of the virtues of the saints, and exhortations to the imitation of their example, and as incentives to the love of God and to the practice of piety' (Sess. xxv. *On the Invocation of Saints*). In many foreign churches, especially in Italy, in southern Germany, and in France, are to be found images which are popularly reputed as especially sacred, and to which, or to prayers offered before which, miraculous effects are ascribed. But instructed Catholics declare that the legends connected with such images form no part of Catholic belief. Most Catholic books of instruction contain cautions against attributing such effects to any special virtue of the images themselves, rather than to the special faith, trustfulness, and fervour which are stirred up by their presence, and by the recorded examples of the mercy of God with which they are associated. For the modern Greek usage, see ICONOCLASTS.

Imago. See INSECT.

Imâm, or IMAM, the officer who in Mohammedan mosques recites the prayers and leads the devotions of the faithful. In Turkey the imâm also performs the ceremonies connected with circumcisions, marriages, and funerals. The prophet Mohammed and his immediate successors bore the title Imâm, because they used personally to conduct the devotions of their followers. Hence the title came to mean head of the faith, and as such is borne by the Sultan of Turkey. For 'the Hidden Imâm,' see ISMAILIS, MAHDI.

Imatra Falls. See FINLAND.

Imbecility. See IDIOCY.

Imbros, or IMBROS, an island of the Egean Sea, belonging to Turkey, about 14 miles N.E. of Lemnos and the same distance W. of the mouth of the Dardanelles. Area, 98 sq. m.; pop. 6000, mostly of Greek descent. The island is mountainous, its highest summit attaining 1950 feet above sea-level. Goats and bees are kept. The inhabitants cultivate the soil and carry on fishing. The chief village, Kastor, is situated on the north coast, and occupies the site of the ancient Thos.

of Imbros. It is the seat of a metropolitan of the Greek Church.

Imeritia, or IMERTITHA. See GEORGIA.

Imitatio Christi, a famous book highly prized by devout Christians of all confessions, and translated into more languages than any book except the Bible. The question of its authorship has given rise to a great controversy. It was formerly attributed unhesitatingly to Thomas à Kempis, and the best authorities still regard it as his work. But it has been claimed for Chancellor Gerson (q.v.), for Gerson, abbot of Vercelli (an apparently hypothetical person), for Walter Hilton, a monk of Sheen in Surrey, for Bonaventura, Bernard of Clairvaux, and for many other writers, both famous and obscure. See KEMPIS (THOMAS A.).

Imitation, in the science of musical composition, is the repeating of the same passage, or the following of a passage with a similar one, in one or more of the other parts or voices, and it may be either strict or free. When the imitated passage is repeated note for note, and every interval is the same, it is called strict, and it may take place in the unison or octave, or in any other of the degrees of the scale, either above or below the original passage. Canon (q.v.) is strict imitation carried on to some length. The progression of a passage may also be imitated by an inversion, or by reversing the movement of the original; also by notes of a greater or of a lesser value (see AUGMENTATION).

Imitation. See MIMICRY.

Immaculate Conception. The Feast of the Immaculate Conception of the Blessed Virgin Mary is celebrated on the 8th of December in the Latin, and on the 9th in the Greek Church, in which latter church it is held under the name of 'The Conception of St. Anne, the mother of the Virgin Mary.' The festival of the Conception itself is traceable in the Greek Church from the end of the 5th century, and in the Latin dates from the 7th; but a great controversy prevailed for a long time in the West as to whether and in what sense the conception of the Blessed Virgin Mary was to be held immaculate, and in what sense the Blessed Virgin herself was to be held conceived without sin. It was believed to be a consequence of the doctrine of the divine maternity, and a necessary part of the honour due to the Incarnation, that the Blessed Mother should be held to have been at all times free from the stain of sin. This might have been either by her having been, like the prophet Jeremiah (Jer. i. 6), or the Baptist St. John (Luke, i. 35), sanctified before her birth;—i.e. purified in her mother's womb from the stain of original sin; or by the still higher sanctification of having been entirely exempted from the stain of sin, either before the formation of the embryo in the womb of her mother, or at least before its animation by union with the soul. The actual controversy in the West may be said to have commenced with St. Bernard, who not only remonstrated with the canons of Lyons in 1131 for their unauthorised introduction of this festival in their cathedral, but rejected the opinion of the Blessed Virgin's having been conceived free from original sin, though he admitted her sanctification in her mother's womb. Duns Scotus, in a disputation held before the university of Paris in 1307, maintained the doctrine of the immaculate conception in its highest sense; and the entire order to which he belonged, the Franciscan, as well as the school to which he has given his name, the Scotists, afterwards zealously defended it. The Thomist school, which was that of the Dominican order, denied the immaculate conception, and much division for a time existed; but the prevailing tendency was at all times towards the Scotist opinion.

The university of Paris in 1387 condemned the Thomist doctrine. The Council of Basel—although, it is true, at the time when it was in conflict with the pope—declared the doctrine of the immaculate conception to be a Catholic dogma, and reprobated in the strongest terms the opposite opinion. Sixtus IV., however, imposed on the defenders of both opinions in 1470 the obligation of mutual toleration and charity, and renewed this constitution in 1483; but the university of Paris required from doctors graduating an oath that they would defend the dogma of the immaculate conception. The Council of Trent merely declared that 'in its decree on original sin it did not comprehend the blessed and immaculate Virgin Mary,' and renewed the constitution of Sixtus IV. This abstinence on the part of the council led to a further renewal of the dispute, which reached such a pitch towards the close of the 16th century that Pius V. not only prohibited either side from stigmatising the opposite with the name of heretical, but forbade all public discussions of the subject, except in theological disputations in the presence of a learned auditory. In the pontificates of Paul V. and Gregory XV. earnest requests were made by the Spanish crown to obtain a definite declaration in favour of the doctrine of the immaculate conception; but the pope again refused, contenting himself with repeating the constitution of Sixtus IV. He added, however, certain new provisions: (1) That disputants, in asserting the doctrine of the immaculate conception, should abstain from assailing the opposite doctrine. (2) That no one except the members of the Dominican order, and others specially privileged, should presume to defend, even in private disputation, the doctrine that the Blessed Virgin Mary was conceived in original sin. (3) That, nevertheless, in the public mass or office of the church, no one should introduce into the prayers or other formulae any other word than simply *conception*, without adding any epithet involving either doctrine. At the same time opinion was setting steadily in favour of the doctrine of the immaculate conception. Alexander VII. and afterwards Clement IX. added new solemnity to the festival. Clement XI. ordained that it should be observed as a holiday of obligation, and at length Gregory XVI. permitted that the epithet immaculate should be introduced into the public service. In the end, at the instance of bishops in various parts of the church, Pope Pius IX. addressed a circular to the bishops of each nation, calling for their opinion, and that of their people, as to the faith of the church on the point; and on the receipt of replies all but absolutely unanimous, he issued a solemn decree at Rome, in a numerous council of bishops, on the 8th December 1854, declaring the doctrine to be an article of Catholic belief, and proposing it as such to the universal church. This decree has been universally accepted throughout the Roman Church.

Immanence, the notion that the intelligent and creative principle of the universe pervades the universe itself, a fundamental conception of Pantheism (q.v.).

Immanuel. See EMMANUEL.

Immermann, KARL LIEBLECHT, dramatist and humorist, was born at Magdeburg on 24th April 1796, and educated at his native town and at Halle, where he opposed the duelling *Burschenschaften* (q.v.). In 1817 he entered the public service of Prussia, and, after serving at Munster, Magdeburg, and Dusseldorf, died at the last-named town on 25th August 1840. For twenty years of his life (1819-39) he was greatly influenced by the Countess von Ahlefeldt, an intellectual lady of literary tastes. Immermann began his

literary career as an adherent of the Romantic school, and in the spirit of that school wrote the comedies *Die Prinzen von Syrakus* (1821) and *Das Auge der Liebe* (1824), and the tragedies *Das Thal von Ronceval* (1822), *König Perintoler* (1823), and others. His later dramatic works, as the trilogy *Alexis* (1832) and the mythical piece *Merlin* (1831), show more originality and fewer traces of Romantic influence. He failed in an endeavour to make the theatre at Dusseldorf, of which he became director in 1835, a model of classic elegance and healthy influence. His fame rests more enduringly upon his tales (*Miscellen*, 1830) and the humorous, satirical novels *Die Epigonen* (1836) and *Mannchenhausen* (1839), (this last the best known of his works and one of the best of German novels. The idyllic portion of *Mannchenhausen* has often been printed separately under the title *Der Oberhof*). Besides these he wrote a mock heroic poem *Falschheit* (1827), the epic *Tristan and Isolde* (1842), and *Memnonbitten* (1840-43), the last two left incomplete. Collected editions of his works were published in 14 vols. (1840-43), and in 20 vols. by Boxberger (1883). See *Life* by his widow, edited by G. von Putlitz (2 vols. 1870).

Immigration. Under the head of Immigration (q.v.) the causes which have led to immigration and the conditions under which movements of population are conducted have been fully described. It is necessary under immigration (entering or passing into a place, as opposed to emigration) to touch on some features of national opinion and policy which have come into existence within the past few years. Until the last few years, with the exception of the immigration of Huguenot families from France to Great Britain after the revocation of the Edict of Nantes, the population of these islands has not been increased from external sources. Since 1880 a considerable influx of the Semitic inhabitants of eastern Europe, principally Polish, Russian, Roumanian, and German Jews, has seriously affected the industrial position of British-born workers in certain trades. Public attention was drawn to the subject in 1888 and 1889 by the appointment of two parliamentary committees, one by the House of Lords on the sweating system, the other by the House of Commons on the question of foreign pauper immigration. These separate inquiries were really directed to the same subject. From the evidence given it appears that the anti-Semitic laws of Russia, Poland, and Germany, aggravated by the hated burden of compulsory military service, have induced considerable bodies of destitute persons, almost exclusively of the Hebrew faith, to seek in England a refuge from civil and religious persecution. Unlike the Huguenots, who brought with them not only capital, industry, and a knowledge of at least two useful trades, silk-weaving and watch-making, the Jewish refugee families arrive in England in a destitute condition. The result of this indigent condition is a willingness to accept the smallest remuneration for the heaviest labour. Sixteen to eighteen hours a day is no unusual period of toil for these pauper immigrants in the boot-finishing trade. The weekly remuneration for this work varies from four to fourteen shillings, according to the skill and industry of the worker. The bearing of these facts on the welfare of British-born workers engaged in the same or in kindred occupations is of a sinister character. Alone of civilised nations Great Britain is without laws to control and if need be check the influx of foreigners, who, contributing nothing to the national revenue, enjoy the privileges without sharing the burdens of citizenship. Public opinion holds jealously to the traditions of hospitality England has always extended to refugees by foreign persecution. Mazzini, Kossuth, and Orsini found

a sanctuary on British soil. It is held that the humbler objects of foreign tyranny shall have no colder welcome measured out to them. The present position of the pauper immigrant question in Great Britain is set forth in the Report of the Select Committee of the House of Commons, 1889, and is to the effect that although no immediate legislation is recommended, the circumstances are such as to require careful watching, with the probability of some restrictive measure being required in the future.

Far otherwise has the question of immigration been dealt with in the United States. By an act passed by congress in 1882 (also the Undesirable Persons Act, 1891) it is provided that passengers arriving from foreign ports shall be subject to examination. If a convict, imbecile, idiot, or any person unable to take care of himself or herself without becoming a public charge be found on board, such persons shall not be allowed to land. In 1898, 3229 persons were sent back to their port of embarkation, 2812 under the above act of 1891, and 417 under the Contract Labour Acts mentioned below. Of the total, 312 were British and Irish. The liability to repatriation acts as a deterrent to the embarkation of persons likely to come under the act. The importation of foreigners and aliens is prohibited in certain cases. By the Alien Contract Labour Laws (1885, 1887, 1888, and 1891) prepayment for transportation of or assisting foreign immigrants under contract for labour or service made previous to emigration, is declared to be unlawful. Any contract so made is void and of no effect. Foreigners temporarily residing in the United States are nevertheless permitted to engage other foreigners as private secretaries, servants, or domestics. Nor are persons prevented from engaging as skilled labourers foreigners in any new industry not established in the United States. The provisions of this act do not apply to professional actors, artists, lecturers or singers, nor to persons employed strictly as personal and domestic servants, nor do they prevent any individual assisting his friends or relatives to emigrate to the United States for the purpose of settlement.

The restriction of the immigration of the Chinese into the United States dates from the completion of the great trans-continental railways. Thrifty, abstemious, and industrious, the Mongolian labourers threatened to lower the wages of the Irish and the native-born Americans. The case for the exclusion of Chinese includes the following points: (1) That they arrive in the country faster than any other kind of immigrant; (2) that the number of Chinese is greater than that of any other race; (3) that they are indisposed to be governed by white men's law; (4) that they are dissimilar in habits and occupation to the English speaking races; (5) that they evade the payment of taxes justly due to the government; (6) that they are governed by pestilential habits; (7) that they are useless in cases of emergency; (8) that they habitually desecrate graveyards by the removal of bodies therefrom; (9) that the laws governing the whites are found to be inapplicable to the Chinese; (10) that they are inclined to habits subversive of the comfort and well being of the community; (11) that they do not come as permanent settlers. To carry out the measures for excluding the Chinese a treaty was concluded between the United States and China in 1880, which was proclaimed the following year. The first and most important article of this treaty stipulates that whenever in the opinion of the government of the United States the coming of Chinese labourers affects or threatens to affect the interests of that country, or to endanger the good order of the said country, or of any locality

within the territory thereof, the government of China agrees that the government of the United States may regulate, limit, or suspend such coming or residence, but may not absolutely prohibit it.' In pursuance of the stipulations in the above treaty congress passed in May 1882 an act declaring that, 'in the opinion of the government of the United States the coming of Chinese labourers to this country endangers the good order of certain localities within the territory thereof,' and it is enacted that the immigration of Chinese labourers be suspended for ten years, and during that time it shall not be lawful for a Chinese labourer to come, or, having come, to remain in the United States. No Chinese are or can be admitted to citizenship. The laws and regulations devised to secure the exclusion of the Chinese are exceedingly stringent. Any person bringing, or causing to be brought, any Chinese person not lawfully entitled to enter the United States is guilty of a misdemeanour, and shall on conviction be fined not exceeding \$1000, and imprisoned for not exceeding one year. Masters of vessels arriving at United States ports must supply to the collector of customs a separate list of Chinese passengers on board. Any refusal or wilful neglect to comply with these provisions subjects the master to the penalties provided for refusal to deliver a manifest of cargo.

Public opinion in the United States is by no means unanimous on the Chinese question. The pressure, however, of the Pacific states has been too strong for resistance by the Atlantic states.

With regard to the laws and regulations prevailing in the larger British colonies, space will not permit their being set forth in detail. The following précis of facts and references will be found useful for further investigations of the subject:

Laws or regulations, if any, in the large colonies prohibiting or restricting the immigration of pauper or infirm persons:

Canada.—See chap. 65 of revised Statutes of Canada, 1886, sections 17 to 24.

New South Wales.—No statute.

Victoria.—Sections 36-39 of Passengers, Harbours, and Navigation Statute, 1865.

South Australia.—The governor has power under the Immigration Act to make rules for repatriating pauper and infirm persons.

Queensland.—No statute.

Tasmania.—Section 3, 49 Viet. No. 4, 1885.

New Zealand.—Imbecile Passengers Act, 1882.

Cape.—No statute.

Natal.—No statute.

The laws of foreign countries respecting the admission and continued residence of destitute aliens are contained in a return presented to parliament in September 1887 (c. 5168, Eyre & Spottiswoode).

The law of the Australasian colonies relating to the Chinese are substantially the same as those prevailing in the United States. See CHINA, Vol. III. p. 193; and COOLIES.

Immorality, in point of law, is a good defence to actions and suits, and obligations and contracts made against good morals are ineffectual at law. Thus, for example, if a man gave a bond, or granted a deed, giving to a woman some annuity, with a view to induce her to live in concubinage, this would be a good defence against the bond or deed being enforced, for the law discountenances his conduct; whereas, if it were merely a bond, or a gift, in consideration of something of the same kind past and ended, the deed would be good. So the keeper of a house of ill fame is not allowed to sue, and has no legal remedy against her guests for any sum agreed to be paid for immoral purposes.

Immortality is the continued existence of the human soul in a future and invisible state. 'If a man die, shall he live again?' is a question which

has naturally agitated the heart and stimulated the intellectual curiosity of man, wherever he has risen above a state of barbarism, and commenced to exercise his intellect at all. The religion of all civilised peoples may be said more or less to recognise the affirmative of the question, although often under very vague and materialistic forms. Some of the most widely-spread forms of belief in the world would seem to be exceptions to this statement; for in Hinduism the goal sought is absorption into the Universal Spirit, and therefore loss of individual existence; while the pious Buddhist strives for *Nirvana*, or complete extinction. Yet even here the belief in a future life exists in the form of Transmigration (q.v.).

In the ancient Egyptian religion the idea of immortality first assumes a definite shape. There is a clear recognition of a dwelling-place of the dead and of a future judgment. Osiris, the beneficent god, judges the dead, and 'having weighed their heart in the scales of justice, he sends the wicked to regions of darkness, while the just are sent to dwell with the god of light.' The latter, we read on an inscription, 'found favour before the great God; they dwell in glory, where they live a heavenly life; the bodies they have quitted will for ever repose in their tombs, whilst they rejoice in the life of the supreme God.' Immortality is plainly taught, but bound up with the idea of the preservation of the body, to which the Egyptians attached great importance, as a condition of the soul's continued life; and hence they built vast tombs, and embalmed their bodies, as if to last for ever. In the Zoroastrian religion the future world, with its governing spirits, plays a prominent part. Under Ormuzd and Ahriman there are ranged regular hierarchies of spirits engaged in a perpetual conflict; and the soul passes into the kingdom of light or of darkness, over which these spirits respectively preside, according as it has lived on the earth well or ill. Whoever has lived in purity, and has not suffered the *daes* (evil spirits) to have any power over him, passes after death into the realms of light. In the early Greek paganism Hades, or the realms of the dead, is the emblem of gloom to the Hellenic imagination. Achilles, the ideal hero, declares that he 'would rather till the ground than live in pale Elysium.' This melancholy view of the future everywhere pervades the Homeric religion. With the progress of Hellenic thought a higher idea of the future is found to characterise both the poetry and philosophy of Greece, till, in the Platonic Socrates, the conception of immortality shines forth with impressive clearness and precision. In the *Apology* and the *Phædo* Socrates discourses of the doctrine of the soul's immortality in language at once rich in faith and in beauty. 'The soul, the immaterial part, being of a nature so superior to the body, can it,' he asks in the *Phædo*, 'as soon as it is separated from the body, be dispersed into nothing, and perish? Oh, far otherwise. Rather will this be the result. If it take its departure in a state of purity, not carrying with it any clinging impurities of the body, impurities which during life it never willingly shared in, but always avoided, gathering itself into itself, and making the separation from the body its aim and study—that is, devoting itself to true philosophy, and studying how to die calmly; for this is true philosophy, is it not?—well, then, so prepared, the soul departs into that invisible region which is of its own nature, the region of the divine, the immortal, the wise, and then its lot is to be happy in a state in which it is freed from fears and wild desires, and the other evils of humanity, and spends the rest of its existence with the gods.'

It is only in Christianity, however, that this higher life is clearly revealed as a reward, not

merely to the true philosopher, but to every humble and pious soul. Christ 'hath brought life and immortality to light by the gospel.' 'According to his abundant mercy, God hath begotten us again unto a lively hope by the resurrection of Jesus-Christ from the dead, to an inheritance incorruptible and undefiled, and that fadeth not away, reserved in heaven.' It is undoubtedly owing to Christianity that the doctrine of the soul's immortality has become a common and well-recognised truth—no mere result of speculation, nor product of priestly invention—but a light to the reason, and a guide to the conscience and conduct. For the Old Testament view see the article HELL; for other questions connected with the future state see the articles ANIMISM, APPARITIONS, CONDITIONAL IMMORTALITY, HEAVEN, ESCHATOLOGY, ORIGIN, PRE-EXISTENCE, SOUL, SPIRITUALISM, THEOSOPHY, UNIVERSALISTS; also Salmon's *Christian Doctrines of Immortality* (1896).

Immortelles. See EVERLASTING FLOWER.

Imola, a town of Italy on an islet in the river Santerno, in the midst of a fruitful plain, 22 miles SE. of Bologna by rail, with manufactures of leather, pottery, silk, and glass. Its cathedral has been spoiled by restoration. Pop. 12,500. Innocenzo di Imola (properly Francucci), a notable painter, was born here in 1494, and did most of his life's work in Bologna, where he died about 1550.

Impanation (Lat. *in*, and *panis*, 'bread'), a technical word formed on the analogy of 'incarnation,' employed in eucharistic controversies as early as the 12th century to express the union of the body of Christ with the consecrated bread in the Eucharist; but later specially used of Luther's doctrine of Consubstantiation (q.v.). See LUTHER, and LORD'S SUPPER.

Impeachment, an exceptional form of process whereby the House of Commons may obtain redress for any unlawful act, and especially for high crimes and misdemeanours committed by peers and ministers of the crown. When the House has resolved on an impeachment certain of its members are deputed to go to the bar of the House of Lords, and there to present the charges they are prepared to support. At the trial the Lords as a body act as judges, the managers appointed by the Commons conduct the prosecution, and the accused may be defended by counsel. For a picturesque description of these proceedings, see Macaulay's *Essay on Warren Hastings*. A pardon by the crown may not be pleaded in bar of an impeachment; but after conviction and sentence the crown may pardon the offender. The last instance of an impeachment is that of Lord Melville in 1805. Impeachment is a form of trial, and is to be distinguished from proceedings by way of Bill of Attainder or Bill of Pains and Penalties. Parliament deals with such bills in its legislative and not in its judicial capacity. In the United States impeachment is a written charge brought by the House of Representatives to the Senate against a civil officer of the United States; or, in the several states, the accusation of an officer by the legislature to the senate of the state. The most famous trial of impeachment in the United States was that of President Johnson (q.v.) in 1868; and he was acquitted under the rule requiring a two-thirds vote of the members present to secure a conviction, the vote standing 35 for and 19 against conviction.

Impenetrability, one of the essential properties of matter, implies that no two bodies can at the same time occupy the same space. If a nail be driven into a piece of wood, it does not, properly speaking, *penetrate* the wood, for the fibres are driven aside before the nail can enter. If a vessel

be filled with fluid, and a solid body be then placed in it, as much water will run over as is equal in bulk to the solid body, in this way making room for it. The lightest gases are really as impenetrable as the densest solid; although, owing to their compressibility, it is not readily made apparent.

Imperative, CATEGORICAL. See KANT, and ETHICS.

Imperial Cities. See FREE CITIES.

Imperial Institute. The Imperial Institute of the United Kingdom, the Colonies, and India, designed to commemorate the jubilee of Queen Victoria (1887), aims at comprising complete collections of the products of the various parts of the British empire, a commercial intelligence department for the promotion of trade and industry, and a great school of modern oriental languages (opened in 1890). In 1890 some £450,000 had been subscribed for the purpose, at home, in Canada, Australia, and India. The foundation of the building costing £300,000 was laid by the Queen in 1887, and the Institute was opened by her on 10th May 1893.

Imperialism, in its original, and, perhaps, its widest sense, was expressed in the great designs of Charlemagne (q.v.). Regarded thus, it amounts to a scheme of undisputed sway over an extensive area of unbroken territory—autoeracy on a grand scale. In that sense we find imperialism in the traditional policy of the czars of Russia—a policy which is supposed to imply continuous expansion to the east. But imperialism, as it came to be known in connection with Germany, does not imply conquest or aggression or annexation of territory. In Germany the policy sprang from the Franco-German war, or rather from the events preceding it, and it meant simply the union, or remission, of the several German states and peoples under one head for purposes of offence and defence, and for certain fiscal and political purposes. As applied in the affairs of the United Kingdom we find imperialism with a twofold signification. It has been in use for a comparatively few years—since about 1878 or 1879—and is usually traced to Lord Beaconsfield (q.v.). That statesman was credited with large dreams of empire for the British crown, and one of his most memorable acts was to have the Queen proclaimed Empress of India. In connection with the British empire, the word imperialism may, however, be used as combining the interests of all the members of the group—the mother-country, the colonies, and dependencies—as distinguished from purely national, colonial, or local concerns. The character and design of such British imperialism are expressed more or less coherently in the schemes of the Imperial Institute and the Imperial Federation League (see COLONY). The term 'Imperial Parliament,' as now applied to the legislature at Westminster, is another expression of the same sentiment. See ABSOLUTISM, AUTOCRACY, CHAUVINISM.

Impetigo Contagiosa, a disease of the skin. It consists of crops of pustules, which may either be scattered or collected in groups. These pustules burst, dry up, and become covered with scabs or crusts of a yellow colour, not unlike little masses of candied honey. From beneath these crusts a purulent discharge commonly exudes; the crusts become thicker and larger, and the skin beneath them is red and raw. The disease is most common in childhood, and generally arises in ill-fed, ill-cared-for children; but it may be transmitted by contact to adults. The head and face are most commonly affected. Local treatment consists in removal of the crust by poulticing, and the application of white precipitate ointment. Attention must be paid to the general health; cod liver oil and other tonic medicines are often desirable.

Impey, SIR ELDON, born in 1732, was educated at Westminster, brought up to the bar, and sent out to Bengal as the first chief justice appointed under the Regulating Act of 1773. He landed in Calcutta, 19th October 1774, in company with his brother judges and the three members of council sent out from England under the same act. From the first Impey acted in harmony with the governor-general, Warren Hastings (q.v.); and in the following year presided at the trial of Maharaja Nand Kumar (Nuncomar), charged with forgery. Impey conducted the trial with fairness and patience; the prisoner, however, was found guilty by the jury, after an impartial charge by the chief justice, who sentenced him to death with the concurrence of a full court. In 1777 Impey was referred to as arbitrator between Hastings and General Clavering when the latter claimed the reversion of the post on Hastings' alleged resignation. Impey pronounced in favour of Hastings; thereby—as the governor-general afterwards acknowledged—saving his fortune, honour, and reputation. In 1779, however, a conflict occurred between the government and the court on a question of jurisdiction, which was only appeased by Impey accepting the chiefship of the Company's courts in addition to his own duties. In 1783 Impey was recalled, and impeached for his conduct in the case of Nuncomar. He was honourably acquitted; Pitt and Dunning and Thurlow all concurred in approving the whole of his conduct. In his retirement he continued to enjoy the friendship of good men. In 1803 he visited Paris, and was for a short time detained by the French government in consequence of the rupture of the peace of Amiens. He died in his house at Newick, near Brighton, 1st October 1809. Impey was a good scholar, both classical and oriental; as a judge he was industrious and free from corruption. His faults were vanity and a tendency to obscuritism.

See HASTINGS; *Life of Sir E. Impey*, by his son, E. B. Impey (1846); *The Story of Nuncomar*, by Sir J. E. Stephen (1885); and Mill's *British India*.

Impeyan. See PHEASANT.

Imphail, the native name of Manipur (q.v.).

Imphée, one of the names of Sorghum or Durra (q.v.).

Implement, in Scotch law, means fulfilment of a contract or decree of the court.

Impluvium. See ATRIUM.

Imponderable Substances, an epithet applied to light, heat, electricity, and magnetism at a time when they were universally considered as matter, in contradistinction to those substances which possessed sensible weight. See HEAT.

Imports and Exports. See BALANCE OF TRADE; also articles on GREAT BRITAIN and other countries.

Impotency. See MARRIAGE.

Impounding. See POUND.

Impressionism, the term applied to a modern school of art which, originating in France, is usually held to have been founded by Edouard Manet, and of which Claude Monet, Degas, Renoir, Pissarro, Sisley, and De Cusane are the best known members. The impressionists may be said to have first appeared before the public in the special exhibition of the works of Manet and his followers which was held in Paris in 1867; and in 1874 and 1876 collections of their works were brought together in the Boulevard des Italiens and in the galleries of Durand Ruel, who in 1882 organised an exhibition of their productions in London; while a series of works by Monet were shown in 1889 in the Goupil Gallery, London. The aim of the impressionists is to rid themselves

of the trammels of artistic tradition, and to look at nature—and portray her—in a fresh and original manner. They therefore strive to avoid such compromises and conventionalities of lighting, composition, &c. as have been frankly accepted by the art of the past, and to render with absolute truth their personal and immediate 'impressions' of nature. The members of the school accordingly separate themselves from the great so-called 'romantic' art of the last generation in France—the art of men like Corot, Decamps, Rousseau, and Daubigny—which is a legitimate and orderly development of the mighty art of the past; and though they have more kinship with these they are also to be distinguished from the *plein-air* painters of modern France, at whose head stands Bastien Lepage, and whose main aim is a careful and strictly scientific accuracy in their relative tones of colour. In their rejection of tradition and desire for a fresh, unconventional rendering of nature the impressionists are at one with the pre-Raphaelites of England; but, while the latter studied nature in a severely detailed and analytical manner, the former look on her in her large relations, and portray only such of her salient features as are visible on a cursory examination, and those they render by brushwork of the slightest, thinnest, and looest description. From the pre-Raphaelites the impressionists are still more definitely separated by their want of care for intellectual or emotional interest in their pictures. In the words of one of their ablest exponents, they hold that the eye of the painter 'should abstract itself from memory, seeing only that which it looks upon, and that as for the first time; and the hand should become an impersonal abstraction, guided only by the will, oblivious of all previous cunning.' In the works of most of the impressionists little selection of subject or care for beauty of colour, form, or expression is visible; and their art, touching as it would seem by an instinctive preference on some of the most unlovely aspects of 19th-century existence, dealing with the life of the jockey and the ballet-girl, and portraying the worst atrocities of modern costume, has frequently fallen into dire depths of ugliness and vulgarity. Certain points of resemblance to the aims and methods of the impressionists are to be found in the works of such able painters as J. M. Whistler and J. S. Sargent, and still more distinctly in those of several of the younger Paris-trained English painters who have exhibited in the Suffolk Street Gallery and in the Nineteenth Century Art Club. In 1889 several young English painters, styling themselves 'London Impressionists, and including B. and W. Sickert, T. Russell, P. W. Steer, and Francis Bate, held an exhibition in the Goupil Gallery, London; and a pamphlet by the last-named painter, *The Naturalist School of Painting* (2d ed. 1887), contains the best exposition of the aims of the English section of the school.

Impressment. See PRESSGANG.

Imprint. See BOOK, Vol. II, p. 303.

Imprisonment. Imprisonment is one of the three classes of punishment for crime, death and penal servitude being the other two. Under certain statutes the punishment of whipping also may be adjudged to juvenile offenders or persons convicted of assaults with violence. It has always been a power inherent in courts of justice to imprison for contempt of their authority, and until lately for non-payment of debt. In criminal proceedings a person may, by a warrant of a justice of peace or magistrate, be imprisoned before trial, provided the justice considers it is not a proper case for allowing bail; and though in minor offences an accused person may insist on being

discharged on tendering sufficient bail, yet in more serious crimes it is in the discretion of the justice to accept or refuse the bail tendered, and on his refusal application may be made to judges of the common law courts to accept bail. In Scotland, when such review is resorted to under the Criminal Procedure Act of 1887, or the Act to amend the Law of Bail, 1888, the court as a general rule leaves the prosecutor's discretion as to bail-ability untouched, and in England the same rule obtains. In both countries the supreme courts will interfere where the question is merely one of amount, or where malice or oppression on the part of the prosecutor is averred; but in Scotland, owing to the system of official as distinguished from private prosecution, such grounds are rarely advanced in support of an application for bail. Imprisonment may be with or without hard labour, or it may be solitary. Every prisoner sentenced to undergo a long term passes a period in solitary confinement, and it is in the power of prison governors to order a return to this, which is considered the hardest part of the term, for any gross breach of discipline. The statutory limit of imprisonment is two years. Penal servitude may be inflicted for life, or any shorter term, but in the case both of imprisonment and penal servitude the convict can at any time, and repeatedly within certain limits, apply to the Home Secretary in England, and to the Scottish Secretary in Scotland, for commutation or remission. The documents are forwarded to the judge who tried his case, and the secretaries are guided in their decision by the report which the judge furnishes. In the general case a fourth or a third is deducted from all terms of penal servitude as a matter of course where the convict has complied with prison rules. In police and other petty offences tried summarily at common law and under a variety of statutes, imprisonment is usually awarded with the option of a fine (discretionary in amount), excepting the case of theft; but all other offences tried before recorder and quarter sessions in England and the sheriff and jury in Scotland are visited with imprisonment, although in a few isolated examples statute gives an option. The unlawful detention of the person by any one, or 'false imprisonment' (in Scotland, 'wrongons'), constitutes a personal injury, and may be treated as a criminal or as a civil offence. When persons tried and convicted are afterwards proved to have been innocent, compensation may be awarded to them, along with a formal pardon.

The subject of imprisonment for debt is discussed at DEBT, Vol. III, p. 717.

Improper House. See NUISANCE.

Impropriation, the transfer to a layman of the revenues of a benefice to which the cure of souls is annexed, with an obligation to provide for the performance of the spiritual duties attached to the benefice. The practice of *impropriation* differs from the somewhat similar but more ancient usage of *appropriation*, inasmuch as the latter supposes the revenues of the appropriated benefice to be transferred to ecclesiastical or quasi-ecclesiastical persons or bodies, as to a certain dignity in a convent, a college, a hospital; while impropriation implies that the temporalities of the benefice are enjoyed by a layman. The practice of impropriation, and still more that of appropriation, as in the case of monasteries, &c., and other religious houses, prevailed extensively in England before the Reformation; and on the suppression of the monasteries all such rights were vested in the crown, and were by the crown freely transferred to laymen, or whose successors in title they have passed by descent and purchase. The spiritual duties of such benefices are discharged by a clergyman, who is

called a vicar, and who receives a certain portion of the emoluments of the living, generally consisting of a part of the glebe-land of the parsonage, together with what are called the 'small tithes' of the parish. A lay impropriator is rector of the parish; as such he has rights over the church of the parish, and is bound to keep it in repair.

Improvisatori, an Italian term, designating poets who without previous preparation compose on a given theme, and who sometimes sing and accompany their voice with a musical instrument. The talent of improvisation is found in races in which the imagination is more than usually alert, as among the ancient Greeks, the Arabs, and in many tribes of negroes. In modern Europe it has been almost entirely confined to Italy, where Petrarch, in the 12th century, introduced the practice of singing improvised verses to the lute; and down to the present day the performances of improvisatori constitute one of the favourite entertainments of the Italians. Far inferior to these are such improvisations as those of Theobald Hook, wonderful as they were. Women have frequently exhibited this talent in a high degree. Improvisation is by no means limited to brief poems of a few verses and of very simple structure, but is often carried on with great art, and in the form and to the length of a tragedy or almost of an epic poem. But such productions when printed have never been found to rise above mere mediocrity. It is worthy of notice that the greater number of the celebrated improvisatori of Italy have been born in Tuscany or the Venetian territory. Siena and Verona have been especially productive of them. Some of the principal are Scratino d'Aquila (1466-1500), Peretti (1680-1747), Metastasio (q.v.), who soon abandoned the art, Zucco (died 1764), Serio and Rossi (both beheaded at Naples in 1799), Gianni (pensioned by Bonaparte), and Tommaso Sgricci (1798-1836). The best-known *improvisatrices* are Maddalena Morelli Fernandez, also called Corilla Olimpica, the original of Madame de Staël's *Corinne* (died 1800), Teresa Bandettini (1763-1837), Rosa Taddei, Signora Mazzei (probably the first in point of talent), and more lately the Sicilian Giovannina Milli.

Imputation is one of the most common technical expressions in Christian theology. It is meant to denote the transference of guilt or of merit of punishment or reward. The doctrine of the imputation of sin, for example, is the doctrine which inculcates that all mankind are sharers in the fact and consequences of Adam's fall from innocence; and the correlative doctrine of the imputation of Christ's righteousness is that which inculcates that the merit or righteousness of Christ is transferred to those who believe in him, or, in other words, that they become sharers in his merit or righteousness. See COVENANT, ATONEMENT.

In Articulo Mortis, i.e. at the moment of death, a legal phrase used in connection with the execution of deeds by persons at the point of death. See WILL.

Incandescence. The hotter a body the greater the disturbance which its particles, always oscillating, set up in the surrounding ether, and the greater is the proportion of ether-waves of short length which are set up. Thus, as a body becomes progressively hotter it first becomes visible in the dark as a fog-gray object (platinum at 300° C., gold at 117° C., and iron, not quite free from rust,

at 377° C.—H. F. Weber), then ash-gray, then yellowish-gray, then faintly red, then red hot, orange, yellowish-white, white hot, and lastly, when there is at very high temperatures a preponderance of the more refrangible rays, it becomes bluish or even distinctly blue, as it seems the sun would appear were it not for our atmosphere (Langley). Incandescence is usually witnessed in solids; in liquids it is not known by sight; in gases we have examples in the hydrogen flame and in the condition of the air traversed by lightning or the electric arc. For incandescent Electric Lamps, see ELECTRIC LIGHT; and for the incandescent gas-light, see GAS-LIGHTING, Vol. V. p. 103.

Incantation, a formula of words said or more frequently sung for purposes of enchantment. The use of such is a persistent feature in sorcery from the earliest times, and we still find them used among savage peoples as spells or charms efficacious for the healing of sickness and the averting of danger, as well as for bringing on rain or invoking any other blessing that is much desired. No less common are malignant spells by means of which evil deities are induced to send sickness or death upon enemies, the darker and malignant side of magic being ever as present to the primitive mind as the beneficent. Such traditional formulas show a marvellously conservative fixity of form—a proof, if such were needed, of their real unreality and practical inefficiency, and that the whole has at no time been other than a dark and blind appeal to unknown forces, without the slightest glimmering of scientific ratiocination, and capable of no improvement. For the same reason ancient or foreign epithets, and terms not merely misunderstood but not understood at all, are often found to have been particularly efficacious, and we find medieval sorcerers in their formulas using transposed letters and artificial words, the traditional Jewish names of demons, as Asmodai and the like, and a gibberish of mixed Hebrew and Greek words more or less consciously confused. Even so late as 1830 in Lincolnshire two Gypsy girls were found using a book of navigation in the process of their fortune-telling. The history of such words as the Gnostic *Abraheas* (q.v.) and the medieval *Abrahadabra* (q.v.) throw great light on the methods of magicians from the earliest ages down to the time when their absurdities disappeared before the dawn of a true scientific method. But it was not merely among the less civilised peoples that such constant use of incantations was made. In ancient Egypt magic was worked into an elaborate system and ritual, and many formulas of such religious magic are preserved. Again, the Babylonians had a great wealth of set formulas by means of which they propitiated or expelled the malignant demons who swarmed around them. In the *Vedas* we constantly meet the *mantras*, corresponding exactly to the *mantram* of the Redskins and the *hordkins* of the Maoris. In the *Odyssey* the kinsmen of Odysseus sing "a song of healing" over the wound given him by the boar's tusk. In the *Kalevala* again we find the song that saves wounds; and nothing is more common in our European traditional folk-tales than the most startling miracles wrought by the repetition of snatches of rhyme. But indeed such traditional refrains are by no means yet extinct in the corners of the most civilised countries, used along with the modern and more legitimate methods of healing, and they even have a defensible use in the soothing effect that an act of faith has upon a simple mind. Thus in Scotland, according to a writer in the *New Statistical Account of Scotland*, "when a person has received a sprain it is customary to apply to an individual practised in casting the "wresting thread." This is a thread spun from black wool,

on which are cast nine knots, and tied round a sprained leg or arm. During the time the operator is putting the thread round the affected limb, he says, but in such a tone of voice as not to be heard by the bystanders, nor even by the person operated upon:

The Lord ride, and the foal slide;
He lighted, and he righted,
Set joint to joint, bone to bone,
And sinew to sinew,
Heal, in the Holy Ghost's name.'

Incarnation, the usual theological term for the union of the divine nature with the human in the divine person of Christ. The word *incarnatio* first occurs in the Latin version of Irenæus, and in the Greek fathers we find its equivalent *sarkosis* and *enanthropōsis*. See CHRIST, JESUS, and Otley's *Doctrine of the Incarnation* (1896).

Incas. See PERU.

Incendiarism. See ARSON, EPIDEMIC.

Incense, a perfume, the odour of which is evolved by burning, especially in religious worship. The incense at present in use consists of some resinous base, such as gum olibanum, mingled with odoriferous gums, balsams, &c. There is no regular formula for it, almost every maker having his own peculiar recipe. The ingredients are usually olibanum, benzoin, styrax, and powdered cascavilla bark. These materials, well mingled, are so placed in the censer or thurible as to be sprinkled by falling on a hot plate, which immediately volatilises them, and diffuses their odour through the edifice.

In the Catholic Church, both of the West and of the East, incense is used in public worship, more particularly in connection with the eucharistic service, which is regarded as a sacrifice; but such use is implicitly condemned by Tertullian, Lactantius, Augustine, &c., and seems not to have established itself till the 6th or at least the 5th century. In the Roman Catholic Church incense is used in the solemn (or high) mass, in the consecration of churches, in solemn consecrations of objects intended for use in public worship, and in the burial of the dead. There are also minor incensations of the celebrating bishop or priest and inferior ministers; of prelates, princes, and other dignitaries officially present at the service; and a general incensation of the whole congregation.

In the Reformed churches the use of incense was abandoned at the same time with other practices which have been laid aside by them as without 'warrant of Scripture.' It has been revived by some Ritualists, but was prohibited by the Archbishops of Canterbury and York in July 1899. See CENSER, FRANKINCENSE.

Incest (Lat. *in*, 'not,' and *castus*, 'chaste') is the marrying of a person within the Levitical degrees. In the old ecclesiastical law (now obsolete), and in Scotland, it comprehends cohabitation irrespective of marriage. The law of England, as declared by statutes passed in the reign of Henry VIII., forbids marriage within the prohibited degrees (see CONSANGUINITY). A marriage between a widower and his deceased wife's sister comes within these rules, and is void, and it makes no difference that the marriage was celebrated in a foreign country, as, for example, Denmark, in the United States, or in one of the British colonies, where these marriages are legal, if the parties were domiciled in England, and went abroad merely to evade the English law. It has also been decided in England that the same rules which apply between legitimate relations apply between natural relations, though one is legitimate—as, for example, between a man and the daughter of an illegitimate sister of his deceased wife. Though incestuous marriages are utterly void in England, still it is not a criminal

offence to marry incestuously, not even in those cases in which the connection is most abhorrent to the moral sense of mankind, and the remedy in the ecclesiastical courts may be considered obsolete. In Scotland incest, which is calculated on the same grounds, not only makes a marriage void, but the better opinion is that to marry incestuously, as well as to commit incest, is a capital offence. See MARRIAGE.

Inch. a Gaelic word, corresponding to Irish *innis*, and signifying Island (q.v.); the same root appears in Lat. *ins-ula*. Inch and Innis enter into many compounds, as Inchemahome (an island in the Lake of Menteith), Inniscattery (an island in the estuary of the Shannon), &c.

Inchbald. ELIZABETH, actress, dramatist, and novelist, was the daughter of John Simpson, farmer at Standingfield, Bury St Edmunds, where she was born on 15th October 1753. While quite a girl she determined to become an actress, and when only eighteen left her home to seek a theatrical engagement in London. After a series of strange adventures she betook herself to her relations in London, and with them she met Joseph Inchbald, an obscure actor, whom she married on 9th June 1772. She then went to Bristol, where she made her debut as Cordelia on 4th September 1772; and for some years she played in provincial theatres. Her husband died suddenly in 1779, and in 1780 (3d October) she appeared in London, playing Bellario in *Philaster*, at Covent Garden. Here she remained for nine years, but never rose beyond mediocrity, an impediment in her speech, which was, however, supposed to be cured, being certainly a bar to her progress. But before she left Covent Garden, in 1789, she had found her true vocation — literature, and to it she devoted herself till her powers began to fail. Her earliest efforts were plays, her first being *The Mogul Tale*, a farce produced in July 1784. She wrote or adapted nineteen plays, her best being the comedies of *Such Things are* (1787), *The Maligned Hour* (1787), and *The Wedding Day* (1794); the farces of *Appearance is Against Them* (1785) and *The Widow's Vow* (1786); and her adaptation from Kotzebue, *Lovers' Vows* (1798). She edited the well-known *Inchbald's British Theatre* (25 vols.), a *Modern Theatre* (10 vols.), and a *Collection of Farces* (7 vols.). But her fame rests not upon her dramatic work so much as upon her novels, *A Simple Story* (1791) and *Nature and Art* (1796), which rank among English standard novels. Mrs Inchbald, who was a Catholic, became very devout in her later years, and died at Kensington House (then a Catholic establishment), 1st August 1821. Her biography by Boaden (2 vols. 1833) is one of the most embossed and ill-digested even of that writer's productions. She wrote an autobiography, but destroyed the MS. by the advice of her spiritual director. See the Memoir by William Bell Scott prefixed to a new edition of *A Simple Story and Nature and Art* (1880).

Incidence. ANGLE OF. See OPTICS.

Incedon. CHARLES BENJAMIN, singer, was born at St Kevern, Cornwall, in 1763, was admitted to the choir of Exeter Cathedral at the age of eight, and served in the navy from 1779 to 1783. His voice was now a fine tenor, and in 1784 he made his first appearance at the Southampton Theatre, as Alphonso in the *Castle of Andalusia*. From 1786 to 1790 he sang in the summer at Vauxhall Gardens, and in the winter at Bath. In September 1790 he appeared at Covent Garden Theatre as Dermot in the *Poor Soldier*; and for twenty-five years thereafter he remained unrivalled

as a ballad singer. In 1817 he visited America. Afterwards he travelled through Britain under the style of the 'Wandering Melodist'; and he died at Worcester, 11th February 1826. Incedon's singing was bold and manly, at times full of feeling; his best ballads were such as 'Black-eyed Susan,' 'The Arethusa,' and 'The Storm,' which he sang dressed as a sailor.

Inclination, or DIP. See MAGNETISM.

Inclined Plane. THE, is reckoned one of the mechanical powers, because, by rolling it up a plane, a man may raise a weight which he could not lift. Let us suppose a plane as in the figure, let its length, AB, its height, BC, and its base, CA, be respectively 13, 5, and 12 feet; and let a rolling load of 780 lb. be placed upon it and sustained in position by a pull or push acting up the plane. We

have now three forces in equilibrium: (1) the weight, W, of the body; (2) the resistance, R, of the plane to bending or breaking; and (3) the pull, P, up the plane. These, W, R, and P, are respectively proportional to the length, AB, the base, CA, and the height, BC; and are thus, in the case supposed, respectively 780, 720, and 300 lb. A force which would, if applied vertically, just lift 300 lb., will thus keep a rolling mass of 780 lb. in position upon a smooth inclined plane, the *gradient* of which is 5 (height) in 13 (sloping length); and a force exceeding this would pull the mass up the slope. In every practical case, however, there is a certain force expended in overcoming Friction (q.v.), even on a dead level; in railway trains this is equivalent to vertically lifting about 50 lb. for every ton of dead weight; and when a train leaves a level run to go up a slope of, say, 1 in 80, the engine has then, for every ton of weight, to do work equivalent to vertically lifting 50 lb. + $\frac{1}{80}$ ton = 78 lb., instead of the former 50. The steeper the gradient, therefore, the heavier the pull; and engineers, in roadmaking, avoid as far as possible making steeper slopes than 1 in 20. The inclined plane presents various modifications, such as knives, chisels, axes, wedges, screws; the last two are generally reckoned as distinct mechanical powers, and will be treated each under its own head.

Inclosures. See COMMONS.

In Cœna Domini. a celebrated papal bull, so called from the ancient day of its annual publication, Holy Thursday. It is not, as other bulls, the work of a single pope, but, with additions and modifications at various times, dates back to the middle ages. Its present form, however, it received from the popes Julius II., Paul III., and finally Urban VIII., in 1627, from which year it continued for a century and a half to be published annually on Holy Thursday. It may be briefly described as a summary of ecclesiastical censures, especially of those with which grievous violation of the faith of the church, or of the rights of the church or of the Roman see, are visited; excommunication being denounced against heresy, schism, sacrilege, usurpation of the rights of the church or of the pope, forcible and unlawful seizure of church property, personal violence against ecclesiastics, &c. The bull also denounces other crimes, as piracy, plunder of shipwrecked goods, and forgery. This bull, being regarded by most of the crowned heads of Europe as an infringement of their rights, encountered in the 17th century the determined

opposition of nearly all the courts, even the most Catholic; and at length, in 1770, Clement XIV. discontinued its publication, which has never since been renewed.

Incombustible Fabrics. See FIRE.

Income-tax, a tax directly levied on all persons having incomes above a certain amount. We hear of a tax imposed on property and *incomes* by the English parliament in 1642 during the great Civil War. It became an important feature in the fiscal system during the French war in 1798. It was revived by Sir Robert Peel in 1842, and may now be regarded as permanent. Since 1898 all incomes in Britain under £160 are exempted; deductions are made from incomes between £160 and £400 of £160, between £400 and £500 of £150, between £500 and £600 of £120, and between £600 and £700 of £70. See GREAT BRITAIN, Vol. V, p. 376.

With reference to the equity and reasonableness of the income-tax opinion is divided. The tax is graduated so far; considerations of equity are satisfied by exempting from it an income sufficient for a decent and comfortable maintenance. On the other hand the tax certainly bears an inquisitorial character through the officials of government making investigation into the private affairs of the citizens. Further, as the estimate of income must to a large extent be left to the discretion of the persons taxed, it offers very considerable opportunity for concealment and falsification in the returns; while the conscientious render an account in full, the less scrupulous may pay less than they ought. Also, it is not equitable that incomes gained from hard industrial or professional labour should be taxed as heavily as incomes derived from inherited property. Such considerations have long and vigorously been urged against the income-tax, and it must be admitted that there is much force in them; but there is little prospect of argument taking effect in the abolition of the tax. An increase of income-tax is the great resort of government in times of emergency, particularly during war, or when the fear of war makes special armaments necessary. In 1890 Mr Goschen estimated that every penny added to the tax meant an addition of about £2,200,000 to the revenue (as compared with £800,000 in 1844 under Peel). It is all the more convenient and even indispensable, because taxation in Great Britain is now limited to a very few articles of daily consumption, so that the exchequer has otherwise only narrow scope for increasing the revenue. And, apart from the difficulties of levying it, it must be maintained that the principle of taxing the citizens according to their income, after deducting the minimum necessary for a comfortable living, is perfectly equitable and reasonable.

In the United States an income-tax was imposed in the years 1863-71. It was exempted at first on \$600, then on \$1000, and ultimately on \$2000. Incomes up to \$5000 paid 5 per cent., those between \$5000 and \$10,000, 7 per cent., and all above \$10,000, 10 per cent. An income-tax of 2 per cent. on all incomes over \$4000, enacted in 1894, was declared unconstitutional by the Supreme Court in 1895, as being a direct tax.

Incommensurable. See COMMENSURABLE.

Increment. UNEARNED, is the increase in the rent of land due to the growth of industrial undertakings and of towns, and the general progress of society. Because obtained without exertion or the expenditure of capital on the part of the owners of the land, some economists maintain that it should be specially taxed.

Incubation. THE PERIOD OF, during which birds sit on their eggs before the young are hatched varies in different species, but is nearly constant in

each. In the humming-birds it is only 12 days; in canaries it is from 15 to 18 days; in the raven and in the common fowl it is 21 days; in the duck it is from 28 to 30 days; in the pheasant and in the guinea-fowl it is 28 or 29 days; in the turkey, 30 days; and in the swan, from 40 to 45 days. The degree of heat (about 40° C., 104° F.) necessary for the development of the young is usually supplied by the mother-bird; but in some cases the sunshine (as in ostriches during the day), or the warmth of a nest of decaying plants (as in the Megapodes), is relied upon; nor must it be forgotten that in many Passerine and Running Birds the males take their share, or it may be the entire responsibility of incubation. While the patience of incubation is most emphasised and rewarded among birds, hints of it appear in reptiles—witness the female python; and analogous processes are seen in a few amphibious fishes, and even Invertebrates.

Incubators, or devices for artificial hatching, are used both for practical and scientific purposes at the poultry farm and in the embryological laboratory. From time immemorial the Egyptians have hatched eggs by artificial warmth in peebiar but comparatively simple ovens, and thirty millions of chickens per annum are said to be thus hatched in Egypt. In 1777 Bonnemain devised a hatching apparatus which supplied the Parisian markets with poultry. In 1825 D'Arceet obtained chickens from artificial incubation by means of the thermal waters at Vichy. The *Écocalcibion*, invented by Mr Bucknell, was said to possess a perfect control over temperature from 300° F. to that of cold water for any length of time. The modern incubator consists essentially of a large water-bath and a gas regulator for automatically preventing the rise of temperature above 40° C. The eggs are placed in a tray or drawer, so arranged that the products of the gas combustion are kept away from the eggs, but a supply of fresh air and moisture secured. For embryological purposes the form most used in Great Britain is probably that of the Cambridge Scientific Instrument Company. See OSTRICH-FARMING, POULTRY; also PISCICULTURE.

Incubus. See DEMONOLOGY.

Incumbent, the rector, parson, or vicar holding an ecclesiastical benefice in England. It is the common title in Scotland of episcopal clergymen holding charges.

Incumbered Estates. See ENCUMBERED.

Incunabula. See BIBLIOGRAPHY, Vol. II, p. 132.

Indecent Exposure is a criminal offence both at common law and in England and Ireland also by statute. It is not clearly settled whether more than one person must have witnessed the indecency in order to make it an offence. The exposure must be in some public place, i.e. in a place which may be seen by some considerable number of persons. The offence is punishable summarily by three months' imprisonment. In Scotland indecent practices are also indictable offences, but the law in this respect is somewhat vague, and the punishment is left to the discretion of the court.

Indemnity, an instrument or contract whereby a person is protected against loss, or against the risk of legal proceedings. Fire insurance, for example, is a contract of indemnity; not so life insurance, which is a contract, not to make good an uncertain loss, but to pay a certain reversionary sum. Acts of indemnity are sometimes passed by parliament for the protection of public officers; thus, in 1801 and in 1817 acts were passed to protect officers who had taken part in the apprehension, &c. of persons suspected of treason. From

the year 1727 onward general acts of indemnity were passed from time to time for the benefit of those who omitted to take the oaths of office required by the acts imposing disabilities on dissenters. For the great French war indemnity, see FRANCE, Vol. IV, p. 783.

Indenture, the technical name given in England to a deed under seal, entered into between two or more parties with mutual covenants. Formerly the papers or pieces of parchment on which the duplicate copies of the indenture were executed required to be actually indented—i.e. notched or toothed (Lat. *dent*, 'tooth'), or cut in a wavy line, so as to correspond with each other, but this is no longer necessary. The name is not used in a general sense in Scotland, except in the case of indentures of Apprenticeship (q.v.).

Independence Day, in the United States, falls on the 4th of July, and is observed as a legal holiday. Public meetings are held, orations are delivered, and the general patriotism finds vent in processions and in salvos of artillery, the explosion of crackers, and in displays of fireworks. In the large cities accidents have been not infrequent, and the reckless discharge of firearms is now kept in check. On July 4, 1776, the Declaration of Independence was reported to the continental congress by the chairman; it was read and proclaimed at the state-house on July 8; but it was not signed by all the delegates until August 2, some of them having to wait for instructions from their respective colonies.

Independents, or CONGREGATIONALISTS. The distinctive principle of the Congregational church polity is that every Christian church or congregation is entitled 'to elect its own officers, to manage all its own affairs, and to stand independent of, and irresponsible to all authority, saving that only of the Supreme and Divine Head of the Church, the Lord Jesus Christ.' They regard the Sacred Scriptures as their only standard, and hold that human traditions, fathers and councils, canons and creeds possess no authority over the faith and practice of Christians. Congregationalism denies that there is any authority in Scripture for uniting the churches of a nation or province into one church or corporation to be ruled by a bishop or bishops, superior to the bishops or pastors of particular congregations, or by a presbytery or synod consisting of the pastors or elders of the several congregations of the nation or province. This is the speciality which distinguishes Independency or Congregationalism from Episcopacy and from Presbytery. The term 'Independent' is supposed to have originated in the incidental use of the word in an 'apology' addressed in Latin and English to the British and Continental universities about the year 1604. But the early maintainers of this form of church government were careful to repudiate certain inferences which might be drawn from the use of the word. 'We do profess dependence,' said one of them, 'upon magistrates for civil government and protection; dependence upon Christ and his word for the sovereign government and rule of our administrations; dependence upon the counsel of other churches and synods when our own variance or ignorance may stand in need of such help from them.' The independence claimed was only the right of every individual church to administer its own affairs, free from the control or authoritative jurisdiction of other churches—a right compatible, it was asserted, and is still asserted, with union for the promotion of common ends, and with fraternal aid and counsel in cases of variance or other difficulty. As compared with other societies of Christians who claim spiritual and ecclesiastical independence, this body of Christians may be

defined briefly as independent congregationally, or as 'Congregational Independents.'

Doctrinally the early Independents occupied the same position as the other sections of the Puritan family. They held in substance the evangelical doctrines of the Reformers, of the Westminster Assembly, and of the Thirty-nine Articles.

Not refusing to confess their faith with the other members of the Westminster Assembly, the representatives of the Independents disputed the right of that or any other assembly to confess its faith for posterity, or make that confession binding upon them. Largely Augustinian and Calvinistic in their interpretation of Scripture, Congregationalists have in these later years become more alive to the freedom which their principles involve to interpret Scripture, not according to any one scheme or system, but as loyalty to the light of truth and the spirit of Christianity may dictate. In the reaction which followed the rise of Socialism many Independent societies fettered the use of their property by the insertion of unathletic doctrinal restrictions in their deeds. In later years the use of their property and buildings has been limited only to the catholic interpretation of the teaching of Christ, and what they regard as the New Testament constitution of the religious society.

For the history of this body we must refer to the works named at the end of this article. But it may be mentioned that as early as the days of Queen Elizabeth it was numerous and influential. In a speech made by Sir Walter Raleigh in the House of Commons in 1592, on the subject of a law to transport the Brownists—as they were offensively and untruly named after Robert Browne (q.v.)—he thus refers to their numbers: 'If two or three thousand Brownists meet at the seaside, at whose charge shall they be transported? or whither will you send them? I am sorry for it, but I am afraid there is near twenty thousand of them in England; and when they are gone, who shall maintain their wives and children?' Several eminent men of this body suffered death for their opinions; others were condemned to banishment. The greater part retired to Holland. Numbers sought an asylum in New England; and America still cherishes the memory of the Pilgrim Fathers, as the founders of those institutions which are the sources of her freedom, her intellectual and moral power, and her national elevation.

By the passing of the Act of Uniformity in 1662 the Independents, along with other Nonconformists, were subjected to much suffering. The act required an express assent and consent to everything contained in the revised Prayer-book, and its effect was to cause 1900 or 2000 of the clergy to leave the church. Still the Independents increased; and the Revolution of 1688, and the passing of the Toleration Act in 1689, at length brought them relief. Efforts were made about this time to bring about an accommodation between them and the English Presbyterians; and in 1691 heads of agreement were drawn up, but with little practical result. In 1730 Presbyterians, Baptists, and Independents formed themselves into a united body, under the name of the Three Denominations, for the protection of their civil and religious liberties. The Independents are the largest dissenting body in England except the Wesleyan Methodists. The largest confederation of its churches is 'the Congregational Union of England and Wales,' which is careful to lay down in its basis the principle that 'it shall not, in any case, assume legislative authority, or become a court of appeal.'

An Independent church is, from its very constitution, at liberty to choose any man for its minister whom it considers qualified for the office

—subject only to the check arising from the fact that neighbouring ministers will refuse to ordain or recognise a man whom they have reason to regard as disqualified. But from the beginning the Independents have attached great importance to an educated ministry. Their leaders in the Puritan age, such as Owen, Howe, and Greenhill, were men of great learning, and, as soon as the Act of Toleration in 1689 allowed, measures were taken for securing a succession of educated men.

In 1890 the *Congregational Year-book* reported 4817 churches and preaching stations in the United Kingdom connected with the body, of which 101 were in Scotland, 29 in Ireland, with 91 stations, and in the Channel Islands 11. In Canada there are 184 churches and stations, in Australia 300, in New Zealand 25, in South Africa 41, in Jamaica 41, in British Guiana 38, in India 31, in China 2, on the continent of Europe 4—making a total of 666. There are in all 18 colleges for training ministers, with 62 professors and 472 students; besides the missionary institutes of the London Missionary Society. In 1895 there were 4850 Congregationalist churches in these islands. Their colleges are 'New College,' London, a union of three older colleges—Homerton, Highbury, and Coward—to be ultimately transferred to Cambridge. Cavendish College there having been bought in 1893; Hackney College; Lancashire College, Manchester; Yorkshire College, Bradford—a union of Airedale and Rotherham colleges effected in 1888; Mansfield College, Oxford, formed by the transference in 1886 of Springhill College and its revenues from Birmingham to Oxford, where graduates of any British university are eligible as students, pursuing part of their studies in the theological classes provided by other colleges of the university; Cheshnut College, belonging to Lady Huntingdon's trustees, founded for the preparation of young men for the Christian ministry in any section of the church to which they might be called, but virtually an Independent college; Western College, Plymouth, the oldest of the colleges, dating from 1750; Nottingham and Bristol Institutes for the training of evangelists and village pastors; in Wales, Brecon, Bala, and Bangor; 'Carmarthen Presbyterian College,' governed by Dr Williams' trustees, who are Unitarians, with an Independent theological professor and many Independent students; and the Theological Hall of the Scottish Congregational churches in Edinburgh.

In Scotland Independency may be traced back to the days of the Commonwealth, during which it was imported by the chaplains and soldiers of Cromwell. But the present Independent churches in Scotland owe their origin mainly to a missionary movement in the end of the 18th century, chief among the leaders of which were the brothers Robert and James Haldane, Greville Ewing, John Campbell, and John Aikman. The Haldanes became Baptists in course of time—a circumstance which greatly divided and weakened the new community. The formation of an academy for the training of ministers in 1811, and of the Congregational Union about the same time, did much to restore the lost vigour of the body. It should be added that the Baptist churches, both in England and Scotland, are as strictly 'Independent' as those which bear that name.

In America the first Independent church was founded at Plymouth, New England, in 1620 by a party of pilgrims sent from Holland by John Robinson. In 1637 the spread of Antinomian doctrine caused much discussion in the church. By a synod convened in New England Antinomianism (q.v.) was unanimously condemned. In 1638 Harvard College was founded. In 1658 the Savoy Confession was adopted. It still remains

in force. Unitarian principles spread about 1750 widely in the Congregational churches of America. In 1785 a separation took place between the Unitarians and the Trinitarians, but both still retain the Congregational form of church government. In 1883 the Unitarian churches of this order numbered 360. There is a Unitarian theological seminary at Meadville, Pennsylvania, and Harvard (q.v.) has only of late years been professedly non-sectarian. 'Congregationalism,' according to Dr Schaff, 'is the ruling sect of the six north-eastern states, and has exerted, and still exerts, a beneficial influence upon the religious, social, and political life of the whole nation.' American Congregationalism is somewhat nearer to Presbyterianism than the English type. In addition to the Conference, or Association of Churches, by which they co-operate for common ends, a national council meets triennially 'for advisory and not juridical ends,' but this council is the recognised agency for deciding as to ministerial or ecclesiastical fellowship. In 1895 the number of Congregational churches in the United States was about 4800, with 515,000 church members, and nearly 600,000 children in Sunday-schools. Besides such well-known colleges as Bowdoin, Amherst, Williams, and Oberlin, the American Independents possess theological seminaries at Andover, Bangor, New Haven, Hartford, Oakland, Chicago, and elsewhere.

Fletcher's *History of Independency*; Waddington's *Congregational History, 1200 to 1850*; Hanbury's *Memorials*; Neal's *History of the Puritans*; Dr Stoughton's *Ecclesiastical History of England*; Skeat's *History of the Free Churches of England*; and Barclay's *Inner Life of the Religious Societies of the Commonwealth*. For the scriptural and apostolic basis of the system, Independents refer to Whately's *Kingdom of Christ* and Hatch's *Bampton Lectures* (1880). See also the article PURITANS.

Index (in full, INDEX LIBRORUM PROHIBITORUM or EXPURGANDORUM), a catalogue published by papal authority in the Roman Catholic Church of books the reading of which is prohibited to members of that church, whether on doctrinal, moral, or religious grounds. As a natural consequence of the claim of the Catholic Church to authority in matters of religion, and to infallibility, that church also claims the right or the duty of watching over the faith of its members, and of guarding it against every danger of corruption, the chief among which is held to be the circulation of books believed to be injurious to faith or to morality. The earliest recorded exercise of this restrictive authority is the prohibition of the writings of Arius. The earliest example of a prohibitory catalogue is found in the decree of a council held at Rome (491) under Pope Gelasius, which, having enumerated the canonical books of Scripture and other approved works, recites also the apocryphal books, together with a long list of heretical authors, whose writings it prohibits. The medieval popes and councils pursued the same course as to the heterodox or dangerous writings of their respective periods; and the multiplication of such books after the invention of printing led to a more stringent as well as more systematic procedure. The university press of Louvain issued in 1546, and again in 1550, a catalogue of prohibited books. Similar lists appeared by authority at Venice, Paris, and Cologne; and Pius IV. issued in 1557 and 1559 what may be regarded as properly the first Roman Index. One of the gravest undertakings of the Council of Trent was a more complete and authoritative enumeration of all those books the use of which it was expedient to prohibit to the faithful. A committee was appointed for

the purpose. But it was found impossible to bring the examination of the books to an end before the close of the council; and the entire papers of the committee were handed over by the council to the pope, with instructions that the work should be completed, and the result published by his own authority, which was accordingly done by Pius IV. in 1564. Further additions and certain modifications of its rules were made by Sixtus V. and Clement VII. It was republished in 1595, and, with the addition of such books as from time to time it was deemed expedient to prohibit, in several subsequent editions, the most remarkable of which are those of Brasichelli (Rome, 1607); Quiroga (Salamanca, 1601); and Sotomayor, *Noctissimus Index* (Madrid, 1648). The edition best known to modern theological readers is that of Rome (1819).

The prohibitions of the Roman Index are of two classes, either absolute and total or partial and provisional, until the book shall have been corrected. The ground of the prohibition may be either the authorship of the work, or its subject, or both together. Under the first head are prohibited all the writings of *heresiarchs*—i.e. the first founders of heresies—no matter what may be the subject. Under the second head are prohibited all books confessedly immoral, and all books on magic, necromancy, &c. Under the third are prohibited all books of heretical authorship treating on doctrinal subjects; all versions of the Bible by heretical authors; and all books, no matter by whom written, which contain statements, doctrines, or insinuations prejudicial to the Catholic religion. The preparation of the Index, in the first instance, was committed to the care of the Congregation of the Inquisition in Rome; but a special Congregation of the Index was established by Pius V., and more fully organised by Sixtus V. This congregation consists of a prefect (who is always a cardinal), of cardinals, of consultants, and of examiners of books (*quidificatores*). Its proceedings are governed by rules which have been authoritatively laid down by several popes, especially by Benedict XIV., in a constitution issued July 10, 1753. The growth of modern literature has, of course, entirely outstripped the limited and tardy machinery of this tribunal. A very small proportion even of the most anti-Catholic publications outside of Italy appear even by name in the Roman Index; but, besides the positive prohibitions of the Index itself, there are certain general rules regarding the use of books by which the freedom of what is considered perilous or pernicious reading is much limited among members of the Roman Catholic Church.

In this list—so objectionable to Protestants as striking at liberty of private judgment, may be found the works of Jewel, Usher, Sanderson, Bull, and Pearson, but not the most really formidable English attacks on Romanism, the works of Chillingworth and Hooker, not to speak of Milton, Bunyan, and Swift. Other English works condemned are Chaucer, Spenser, Addison, Goldsmith, and Macaulay. The Index is revised and extended from time to time—as in 1888; and single articles in magazines may be specially censured—as the articles by Mr St George Mivart, a Catholic, on 'Happiness in Hell' in the *Nineteenth Century* for 1892.

Indexing. The need of indexing has become more urgent as the mass of materials to be indexed has increased, and the circle of those who wish to use these materials has become wider. Lord Campbell proposed to bring a bill into parliament to deprive an author who published a book without an index of the privilege of copyright. There are two classes of books to be indexed—viz. books of facts and books of opinion. In the indexing of the first class, experience, care, and common sense are needed, and the work must be systematic and not casual. In the second class these qualifications are required and something else—viz. the insight of the

precis writer. The indexer must understand his subject and also understand the wants of the reader. The index must be exhaustive in its indication of the various points in the book, and concise in expression, and in addition the indexer must be careful in the choice of catchwords or titles for his headings. He must gather together the same subjects under one heading, and see that they are not separated under synonyms. An author frequently uses periphrases to escape from the repetition of the same fact in the same form; but these periphrases will give little information when inserted as headings in an index, and it is in this power of selecting the best catchword that the good indexer will show his superiority over the commonplace worker. The meaning of the word index has gradually grown from the general to the particular, and the word is now established as denoting a series of references arranged in alphabetical order. There are other kinds of indexes; but these require an explanatory adjective, as classified, chronological, &c. In indexing names it is most important to specify the cause of reference, as a block list of references after a name is almost useless. A colossal instance of this fault will be found in Ayseongh's index to the *Gentleman's Magazine*, where all the references under one surname are placed together without even the distinction of the Christian name. There are 2411 entries under Smith, and it has been calculated that to go through this mass in order to find say Zachary Smith would take the consulter eight days of ten hours a day. It is also important to bring all the references to one man under one heading, and not to separate them under the different names or titles he may have borne. In the index to Scott's edition of Swift's Works there are 638 references to Harley, Earl of Oxford, arranged thus: 227 under Robert Harley, 111 under Lord Oxford, and 300 under Treasurer (Lord Oxford). There should be one index for a complete work and not a separate index for each volume. Again, no classification should be allowed in an alphabetical index. This vicious habit of classification makes the indexes of some well-known papers practically valueless. The consulter of the index wishes to find whether the volume contains anything on a particular subject, and he is only confused and annoyed if he has to look in a succession of alphabets arranged under such headings as original articles, notes, correspondence, &c. The preparation of an index consists of three divisions: (1) compilation, (2) arrangement, (3) printing. Each indexer will find out the mode of procedure which is most suitable for himself; but it may be said generally that foolscap paper is the most convenient size for use. Those entries which are not likely to be repeated can be written down on the page as they occur; but in the case of large headings it will be more convenient to use a separate page for each, and keep these pages in an alphabetised guard book so that they can be turned to in a moment. When the time comes to cut up the index and arrange it in alphabetical order, it will be necessary to see that there are no repetitions of the same subjects under various synonyms. Now is the time to make the cross references, and here considerable judgment is required. When the entries are short and few, it is better to repeat them than to refer from one to the other; but in the case of long entries cross references are very advantageous, and it is always well to refer to cognate headings. No reference to the contents of a general heading which is without subdivision should be allowed. If a general heading is divided into sections, and each of them is clearly defined, they should be 'cross referenced,' but not otherwise. When the arrangement of the cut up slips is undertaken some alterations and revision

of headings will frequently be found advisable. The value of an index is greatly enhanced by the proper setting out of the entries with judicious use of different types. When a book is a complete treatise on a special subject, a well-made index will form an admirable key to the subject and be in itself intrinsically useful. Indexes may also be made with regard to a particular subject dealt with in a number of books.

The Index Society, to form a library of indexes, and to make indexes to important books, rare serials, &c. was founded in 1877, and subsequently incorporated with the British Records Society; their publications appear quarterly in the Index Library. The American Library Association Index (1893) indexed 3000 miscellaneous volumes. See books mentioned in the article BIBLIOGRAPHY, and H. B. Wheatley's *How to Catalogue a Library* (1890).

India, an extensive region of southern Asia, and next after China the most populous area in the world. It was celebrated during many ages for its riches and natural productions, its beautiful manufactures and costly merchandise, the magnificence of its sovereigns, and the early civilisation of its people. It possesses especial interest to British people from the imperial connection of its history with that of their own nation. It affords, too, the greatest market in the world for British textile manufactures, and a great field for the employment of British capital.

Nomenclature.—The name India comes to us, through the Romans, from the Greeks, who borrowed it from the Persians. The latter applied the name Hind to the dwellers in the basin of the Sindhu River, a Sanskrit name for the Indus. Sindhu, by the regular change of *s* into *h*, becomes Hind. The river is still called Sind; while the land is Hind. Officially, then, the country is Hind in the vernacular, and India in English. The national name Hindu is derived from Hind. Then from Hindu came the name Hindustan, which is only a province—viz. the region of the Jumna and the Ganges. This name has sometimes been applied to India as a whole, but this is quite erroneous.

Geographers write of Further India and Hither India. The former, lying eastward beyond the Malay Peninsula, is mostly in native hands, and partly under French protection. The latter is under British dominion, and is in legal phrase India. It was in 1877 proclaimed as the Indian empire. This article will refer only to the official India thus indicated. It will for method and condensation be divided into five parts—I. The Land; II. The People; III. The Government and the Military Defence; IV. The Civil Administration; V. The History.

I. THE LAND.

India is the central peninsula of southern Asia, and lies in 8° 4'—35° N. lat. and 67°—92° E. long. According to these limits, its length may be stated approximately at 1900 miles, and its breadth, reckoned along the parallel of 25° N. lat., at 1600 miles, with an area of at least 1,350,000 sq. m. But in round numbers the square miles contained in this area may be reckoned at one million and a half—inclusive of Burma. The natural boundaries of this vast region are, on the N., the range of the Himalaya Mountains, which separates it from Tartary, China, and Tibet; on the W. the Suliman Mountains, dividing it from Afghanistan and Beluchistan; on the SW. and S. the Arabian Sea and the Indian Ocean; on the E. the hill-ranges which border upon Burma, and the Bay of Bengal. From the mouths of the Brahmaputra on the eastern side, and of the Indus on the western side, the two coasts, east and west, incline towards the

same point, and meet at Cape Comorin, thus producing the form of an inverted triangle. The two sides of the triangle have together a coast-line of about 2000 miles. Thus southern and central, or as it may be called peninsular India, is from its extent of seaboard a maritime country. It is northern India only that has a continental character.

Geography.—For the geography of India there exist excellent materials from the *Grand Trigonometrical Survey*—a work of the highest scientific value—which has determined the height of the mountains and the situation of all the principal places; from the topographical survey, which has displayed the contour and configuration of the whole country; from the revenue and cadastral surveys, which have delineated the boundaries not only of villages but of fields also for all provinces except Bengal and Behar. The region presents a diversified surface and scenery. It has indeed been called 'an epitome of the whole earth,' consisting as it does of mountains far above the level of perpetual snow, broad and fertile plains, bathed in intense sunshine, arid wastes, and impenetrable forests. Its natural divisions are the Himalaya, the sub-Himalayan ranges, the plains of the Ganges and the Brahmaputra, the basin of the Indus, the highlands of Hindustan, the Vindhya and Satpura ranges, and the peninsula south of those ranges.

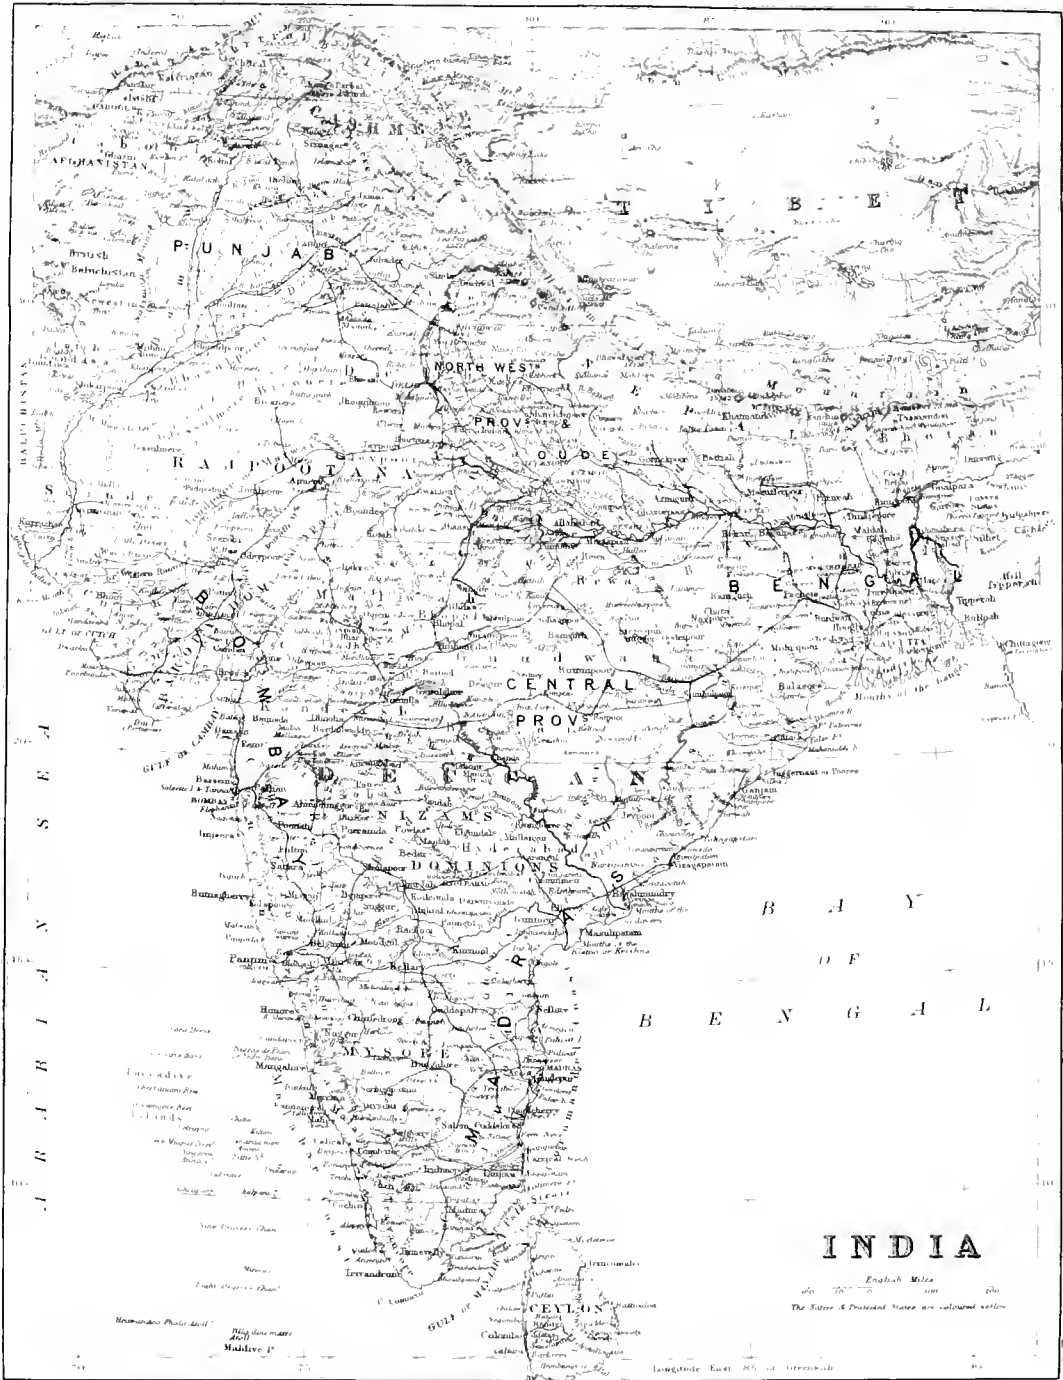

The Himalaya (meaning 'the abode of snow') consists of a chain some 1500 miles in length, in which the links are formed by mountain knots covered with perpetual snow, some of which rise from 20,000 to near 30,000 feet above sea-level, and are the highest yet discovered in the world. It is the dominating factor in the geography of northern India, being the source of the Indus, the Ganges, the Brahmaputra, and of their principal affluents. See HIMALAYA.

The sub-Himalayan ranges run between the chain of the Himalaya and the plains of the Ganges and Indus. They occupy Cashmere, the Simla hill-states, Gurhwal, Kumaon, Nepal, Sikkim, and Bhutan, which, owing to their elevation above the sea (5000 to 9000 feet), have a climate like central Europe in summer and cold as Switzerland in winter, with the vegetation of the temperate zones. These regions are separated from the plain of the Ganges by the submontane tract called Terai, which extends in a long belt, 5 to 25 miles in width, from Hurdwar (where the Ganges issues from the sub-Himalayan ranges) to the Brahmaputra. It is covered with forest, and is the haunt of wild beasts. The soil is very fertile, but malaria has rendered it uninhabitable by man and the domestic animals, at least from April to October. This wilderness is being gradually narrowed or invaded by the progress of drainage and cultivation.

The plains of the Ganges and the Brahmaputra, which include Bengal, Behar, the Doab (meaning the 'Mesopotamia' of the Ganges and Jumna rivers), Oudh, and Rohilkund, form an alluvial flat, terminating in a delta, and extending from the Bay of Bengal to the slight uplands on the Punjab border that form the water-parting between the Ganges and the Indus. Throughout its entire length the Ganges and its numerous tributaries spread out like the veins of a leaf, carrying everywhere their fertilising influence. The population of these fertile and well-cultivated plains is very dense.

The basin of the Indus, in the north-west, is towards the south separated from that of the Ganges by the Aravalli Hills. The Punjab occupies the northern portion. South of the Punjab, and parallel with the river, the great sandy desert of the Indus extends for nearly 500 miles. The valley of the Indus is continued through Sind to the

Arabian Sea. Between the Indus region and the Aravalli Hills lies the Thar desert, an expanse covered with sandhills, 400 miles long and 100 broad. It is only in the neighbourhood of the Indus and some of its tributaries that the surface can be cultivated by means of river-irrigation—although crops of grain may be grown in hollows and narrow valleys after the rains. The horse and camel alone can cross this desert, which is described in Hindu geography as 'the region of death.'

The highlands of Hindustan extend from the Vindhya and Satpura mountains as a base to the border of the Thar desert. They include the tableland of Malwa and Rajputana or Rajasthan, which has an elevation of about 2000 feet above the level of the sea.

The Vindhya and Satpura ranges are two hill-chains, with an elevation from 2500 to 4000 feet, partly though not entirely parallel from east to west, and divided from each other by the valley of the Nerbudda River. They form what may be called the backbone of middle India, or, by another metaphor, a broad wall dividing northern from southern India.

The peninsula south of the Satpura range is in two divisions. The first is the Deccan (q.v.), which name means 'the south.' This area is a central tableland extending from 12° to 21° N. lat., rising from 1500 to 2000 feet above the sea, and enclosed on all sides by mountain-ranges. These ranges are the Satpuras above mentioned, the Eastern Ghâts, somewhat low, facing the Bay of Bengal, and the Western Ghâts, higher and more important, facing the Indian Ocean. Between the Eastern Ghâts and the sea are fertile littoral tracts known to history as the Northern Circars and the Carnatic. Between the Western Ghâts and sea is a similar tract known geographically as the Konkan. As a northern continuation of this tract is Gujarat, with its offshoots the peninsulas of Kathiawar and Cutch. From the low land of the Konkan to the Deccan plateau the mountains rise in a succession of geological formations looking like gigantic terraces. The rivers of the Deccan rise in the Western Ghâts, and, after traversing the tableland, descend to the sea by passages through the Eastern Ghâts. The slope of the country corresponds with the course of the rivers; it has a gradual inclination towards the east. The second division begins technically from the Tungabhadra River, but geographically from the hills south of Cuddapah. It extends right down to Cape Comorin, the apex of the inverted triangle, and includes Madras, Tanjore, Trichinopoly, Tinnevely, and other famous places.

To this summary of natural divisions a brief notice of the mountains and rivers may be added.

The *mountain-system* forms a connected whole. It is separate from the Himalaya and from the Suliman range, which forms a wall between India and Afghanistan. It may best be followed from the southern point, Cape Comorin, northwards, thus: From that point there run upwards two long lines of hills and mountains, one north-easterly, the other north-westerly. The north-easterly line comprises the Eastern Ghâts already mentioned, which become merged in the hilly region on the west of Bengal, and runs up to the neighbourhood of Allahabad, at the junction of the Jumna and the Ganges. This line nowhere exceeds an altitude of 3500 feet above sea-level. The north-westerly line comprises the Travancore and Palni hills, the Nilgiri, the Western Ghâts, the Aravallis, and the Rajasthan hills, up to the neighbourhood of Delhi. This line has at several places considerable altitude, for example in the Nilgiri ('Blue Peak'), 8000 feet and upward; and Mahabaleswar (near Poona) and Abu in Rajputana, upwards of 4000 feet. These

two lines are as the sides of a triangle, and are joined at the top by the two transverse and parallel ranges of the Vindhya and Satpura already mentioned. Thus the mountain-system, like the external configuration of the country, is in the shape of an inverted triangle.

The *river-system* may be thus epitomised. The Indus in the north-west, with a course of 900 miles after issuing from the Himalayas, drains with its four famous affluents, the Sutlej, the Ravi, the Chenab, and the Jhelum, about 300,000 sq. m., and empties itself into the Arabian Sea. In the north-east the Ganges, with the Jumna and other affluents, and the Brahmaputra and Meghna—all which join in the Bengal delta—drain about 500,000 sq. m. Owing to their virtual amalgamation in Bengal, it is difficult to assign a length to the courses of these rivers, which empty themselves in the Bay of Bengal. The central region—viz. that of the Vindhyas and the Satpura—about 100,000 sq. m.—is drained by the Nerbudda and the Tapti, the former having a course of 800 miles, the latter of 400 miles, and both flowing west into the Gulf of Cambay, a branch of the Arabian Sea. The remaining area (viz. 600,000 sq. m., out of a total of 1,500,000) consists of the Deccan and the peninsula. It is drained by the following rivers: Mahanadi, with a course of 520 miles; Godavari, 898; Krishna, 800; Tungabhadra, 400; Pennar, 350; and Kaveri, 470. There are many other rivers which cannot be particularised here. Among them may be mentioned the Hooghly and the Gumbi, Calcutta being situated on the former and Lucknow on the latter; both belong to the Gangetic system.

Geology.—In 1856 a staff of geologists commenced a geological survey of India, which has since then been steadily continued. They have examined an area several times as large as that of Great Britain, and supplied for the districts with which they have dealt an accurate knowledge of the mineral resources.

Professor Medlicott summarises the general result thus. 'Geologically India is divided into three distinct areas: (1) peninsular and (2) extrapeninsular, separated by (3) the Indo-Gangetic plains, formed of the deposits of those great rivers and their tributaries. (1) is a land surface of immense antiquity, all the fossiliferous rocks within it being of aerial or fluvialite formation, and the newest of them of Lower Tertiary age. It is principally a *massif* of gneissic rocks, with bands and basins of transition strata of various ages, culminating in the Vindhyan formation, of unaltered and undisturbed strata, yet of undetermined age, being unfossiliferous. Totally separate from the Vindhyan comes the Gondwana formation: near its base the Indian coal-measures on Upper Palaeozoic, while the top group, where near the coasts, contains Upper Jurassic marine fossils. A great volcanic formation, known as the Deccan Trap, covers an immense area in Bombay and Central India; the deposits locally found in it contain only fresh-water fossils; in Gujarat it occurs between Eocene and Cretaceous marine strata. Along the outer margin of the plains (2) presents an almost unbroken face of Tertiary rocks, of immense thickness, and more or less intensely disturbed. On the west, associated with Cretaceous strata, they extend to form the uplands of Afghanistan and Persia. On the east, again associated with Upper Secondary beds, they abut against the crystalline rocks of the Malayan axis. On the north they form the sub-Himalayan chain at the base of the central Asian *massif*, the southern ridges of which form the Himalayas; in this position the Tertiary series, except at its very base, is inclusively of fluvialite formation, like

the plains, and contains the famous Siwalik mammalian fauna. The outer Himalayan is formed of crystalline and other rocks of uncertain age; but on the north side of the range there is a full succession of Palaeozoic and Secondary marine formations. At the north-east angle of the plains the Shillong plateau of crystalline rocks, capped by horizontal Tertiary strata, separating the lower Assam valley from Sylhet in eastern Bengal, is an outlier of the peninsular massif. At the north-west angle of the plains, in the Salt Range of the Punjab, there is again a small exposure of the ancient limit of the peninsular massif, presenting an outcrop of coastal deposits of Palaeozoic age. Besides the Gondwana coal, a light coal occurs sporadically in the Tertiary rocks from Sind to Cashmere, and in upper Assam there are rich coal-measures of about the same age; in both these regions, also, petroleum is more or less abundant. Pure iron ores are abundant throughout the peninsula and in the outer Himalaya; other ores are comparatively scarce, except along the Malayan axis. The diamonds of India and the aluminous gems of Burma are well known.

In ancient times there were gold-mines in the mountains of the south-western regions, which supplied the metal for the gold coinage which was then almost universal in the country. The most accessible parts of the auriferous strata have been worked out ages ago, and the remnant forms what is known as the Mysore mines. There are other auriferous deposits in parts of the Deccan. Silver has never been discovered in any appreciable quantity within the country; but in the middle ages it was introduced largely from across the Himalayas and used for coinage. In the Shan dependencies of Burma, however, it is extracted from lead ore. Coal is obtained largely in western Bengal, in the Satpura Hills to a considerable extent, and in the Deccan to some extent, and in some other places also—enough, on the whole, to supply the railways. Iron and copper are found and worked in many parts of the country. There are many other mineral products of lesser importance. Diamonds are still found in the central hills, and ruby mines are worked near the Irawadi. The mineral resources on the whole are inferior in importance to the agricultural. See the *Manual of the Geology of India*, by Medlicott, Blanford, and Ball (3 vols. 1879-81).

Climate. It follows from the foregoing summary of geography in a country extending over 26° of latitude—one extremity of which runs far into the torrid zone, and the other terminates in a range of mountains rising far above the line of perpetual snow—a country embracing lowland plains, elevated plateaus, and alpine regions, that the climate must be extremely varied. The whole country has three well marked seasons—the cool, the hot, and the rainy. This characteristic applies without distinction to all parts of the country; even to the Himalayas, which have otherwise a climate like that of Switzerland. The cool months are November, December, January, and a part of February; the dry hot weather precedes, and the moist hot weather follows the periodical rains. The rainy season falls in the middle of summer; its beginning is earlier or later according to circumstances, its ending is in September. But in Burma it lasts longer; and in the peninsula there is a second rainy season, called the latter rains, during the autumn. The winter is the pleasant period; the spring is generally hot and healthy; the summer depends on the duration of the rains; the autumn is close, malarious, and unhealthy. The rainy season everywhere comes from the same cause viz. the attraction by the sun of moisture from the ocean in clouds, and their condensation into rain

upon the land. It is called monsoon, probably a corruption of the Persian word for season (see MONSOON). It is the occasional failure of the monsoons that causes the periodical famines to which the country is liable. The central tableland is cool comparatively, but the alternations of heat and cold differ greatly elsewhere. In the north-west there is burning heat with hot winds in summer, and frost at night in winter. In the south the heat is more tempered, but the winter is cool only, and not cold. At Ootacamund, on the Nilgiris, 7200 feet above the level of the sea, the mean annual temperature is 58 F.; at Madras, 83; Bombay, 84; Calcutta, 79; Bangalore, 74; and at Delhi, 72°. But at places like Delhi, where the heat of summer is tremendous, the average is reduced by the cold in winter. The fall of rain varies greatly in different parts of the country. In the north-eastern and other outlying parts it exceeds 75 inches; at one observatory in north-east Bengal, Cherra Punji, there is a phenomenal fall of 600 inches in the year. In the Deccan, in the upper basins of the Ganges and the Indus, it is 30, and in the lower regions of the Indus less than 15 inches. The remainder of India is placed between the extremes represented by these damp and dry belts, but is, as compared with Europe, an arid country. Hence the necessity of tanks and irrigation canals to supply moisture to the soil, and to obviate the danger of drought and famine. A meteorological department has been established, with 161 observatories, the chief of which are at Calcutta and Bombay. See Henry F. Blanford's *Practical Guide to the Climates and Weather of India* (1889).

Fauna.—The domesticated animals are, first, the cattle—cows, buffaloes, oxen; the last two do the work of agriculture. The bull and cow are sacred animals to Hindus, and by them are never killed for food. The indigenous breeds of horses in India are being improved by the importation of foreign sires. They have never been employed in agriculture. The pony, the donkey, and the mule are largely used. Sheep and goats are abundant. The pig is plentiful, but is despised by the upper and middle classes of the people. The monkeys are tame and are held sacred. The wild animals include the tiger, panther, cheetah, boar, bear, bison, elephant, and rhinoceros. The crocodile and alligator infest most of the rivers. Deer of all sorts abound everywhere, and mainly supply sustenance to the carnivorous animals. The lion, the hyena, the lynx, and the wolf are unimportant. The elephant is used only for purposes of war or of state, both by the government and by the native nobility. The ibex and the ovis-ammou (the wild goat and the wild sheep) are found only in the highest parts of the Himalayas. Poisonous snakes abound, the worst being the cobra da capello (the black-hooded); many thousands of the natives die from snake-bite in the year. The government offer rewards, and many thousands of animals, including snakes, are destroyed. The area supporting these animals has shrunk during the present century from the spread of cultivation, and is still shrinking. Destructive visitations of locusts happen occasionally. The birds are, of course, infinitely various; but several of the most beautiful or remarkable species are wanting. The eagle is found only in the Himalayas, so is the pheasant. The partridge is seen in all the plains, and in some places the quail is abundant. The snipe is found in the marshy land; waterfowl swarm in some localities, and flights of wild geese sweep through the air. Vultures and other birds serve as scavengers. The crow is common everywhere, but not the raven.

At the seaport towns the supply of fish for

European consumption is excellent, and fish-curing is largely practised by the natives. Inland the fishing in the mountain-streams is good, but in the rivers of the champaign the fish, though abundant in quantity, are not esteemed for quality. See W. T. Blanford's *Fauna of British India* (1888) et seq.

Flora.—Nearly half of the country is tropical, though none of it is equatorial, and a part is not only temperate, but cold; accordingly the vegetation varies greatly. As compared with equatorial regions, the country has tropical products plentiful and good, but not first-rate, such as tobacco, sugar, ginger, and spices of all sorts. Rice has from time immemorial been a staple. Maize and millet are articles of food for the stronger races. Oilseeds are largely exported. The cultivation of wheat has greatly developed for exportation since the era of cheap prices. Tea is grown largely under European supervision in the Eastern Himalayas, and already surpasses the China teas. Coffee is grown in the south, but with chequered success. Among the dyes, indigo and lac (red) are noteworthy. European flowers of all sorts are cultivated nowadays. The indigenous flowers are not rich, the water-lilies being the best; the flowering shrubs are very fine, however. Of trees in the plains near the coasts the palm order with its several varieties strikes the observer. Inland the mango fruit-tree and the orange, the umbrageous banyan, the sacred peepul, and the bamboo are features in the landscape. In the hills the teak and other useful timber trees are obtained. In the Himalayas are the cedar, the pine, the fir, the juniper.

The primeval forests which covered the country have long been restricted to the hill and mountain system already described. But further, in this country, as in many other countries, the hills have been deforested by reckless destruction during many generations, to the injury of the climate and of that water-supply on which so much depends. Conservation of forests was not attempted under native rule, nor under British rule until the middle of the 19th century. Since that time, however, a forestry department has been set up as a branch of the administration in every province, with European officers trained in Europe. For the whole country, the forests under supervision amount to 100,000 sq. m., of which two-thirds are under complete conservancy. Besides augmenting the national resources, the forestry is profitable, and yields a net revenue yearly of more than half a million sterling.

The agricultural statistics show that barely one-third of the whole country is cultivated or grazed. Of the remainder a portion is available for cultivation; the rest is uncultivable, consisting of still hill-sides, desert, river-beds, &c.

II. THE PEOPLE.

Population.—This has since the middle of the 19th century been ascertained by census. The decennial census of 1881 showed 253 millions of souls for the whole country, including the British territories and the native states, and an increase of 13 millions over the preceding census. This total was exclusive of the population of the Cashmere state, which really belonged to the country, and of Upper Burma, subsequently annexed. With Cashmere and all Burma the population at the census of 1891 was 287,223,241, an apparent increase of 33,429,917 (deducting the areas not reckoned, a net increase of 27,824,420); and this total excludes Nepal, Bhutan, Sikkim, and the French, Portuguese, and Dutch territories. In round numbers, then, the population may be stated at 290 millions. But though populous the country is not as a whole densely peopled; the

average of inhabitants to the square mile being 229 for the British provinces, 111 for the native states, and 184 for the whole country. The hill and mountain system, indeed, shows a sparse population; but the plains of the Ganges and the Brahmaputra, again, and the coast districts and the southern peninsula, are densely peopled. The Gangetic plain generally has an average of 400 to the sq. m.; and some parts of it, near Benares and Patna, show an average actually double the above, and a density which is quite excessive. Of the 287 millions not more than 30 were urban, the rest being rural. Thus the vast majority of the people live in the country, and most of these are agricultural or pastoral. Everywhere the returns show an excess in the number of males over that of females.

The population of the three presidency cities are: Calcutta, 861,764; Bombay, 821,764; Madras, 452,518. Below these there are twenty-five towns with more than 100,000 inhabitants each, and below these again forty-seven with more than 50,000 each.

Ethnology and Language.—The languages of the present day as well as those spoken in former ages, as far as these are known to us, belong to four different stocks—viz. the Aryan, Dravidian, Kolarian, and Tibeto-Burman stocks. In point of chronological order the Kolarians appear to have been the first settlers, and all indications point to their having originally entered India from the north-east, and having thence spread westwards over the northern plains. As regards the tribes speaking Tibeto-Burman dialects, they are confined to the skirts of the Himalayan range; thus forming, as it were, the southern edge of the wide Tibetan speech-field, having probably penetrated at various times, from the plateau of Tibet, through the numerous passes of the Himalayas. Eastwards, again, these dialects stretch, in a more or less continuous chain, until they merge in the compact body of Burman speech. But whilst a separate linguistic development makes it necessary to treat the Kolarian and Tibeto-Burman languages as two distinct groups, it is yet highly probable that they were ultimately derived from the same Mongol stock. After a time the Kolarian settlers would seem to have been disturbed in their possession of the northern plains by the inroads of Dravidian tribes. These, having gained entrance into India through the north-western passes, seem to have pushed forward, driving the Kolarians into the mountainous districts which border the Gangetic plain in the south, and ultimately to have forced their way through them, and poured themselves in a mighty stream into the southern peninsula. Whether in so doing they were already urged onward by tribes of another race following in their wake we do not know; certain it is, however, that at some time or other subsequent to the immigration of the Dravidians—probably more than 4000 years ago—people of the Aryan stock must have entered the 'land of the five rivers' (Punjab) either through those same passes of the Suliman range, the command of which has so often decided the fate of India, or by a more northerly and yet more rugged route, across the Hindu-Kush, and by way of the Pamir plateau and the highland valley of Cashmere. In favour of this latter alternative it has been urged that there are to this day settled, to the north of Cashmere and Kabul, several tribes of the Aryan stock, such as the Dards and the Sial-Posh Kalins, whose vernacular dialects are of so archaic a character as to have suggested the idea that these tribes may perhaps be the direct descendants of some remnants of the primitive (Indo-Iranic) Aryans which had remained behind in the old homes when the great body of their brethren took their departure in quest of more favoured abodes. However, our knowledge

of these waifs and strays of the Aryan stock is still very imperfect; and they may after all turn out to be mere detached dialects of either the Indic or the Iranic branch of Aryan speech. Between these two divisions no sharp line of demarcation can indeed be drawn; but the languages of the countries west of the Indus—viz. the Pushtu (or Pakhtu) of the Afghans, and the Baluchi, one of the two principal languages of Beluchistan—form intermediate links, being by most scholars included in the Iranian group, whilst others would rather refer them to the Indian division.

(1) *Indo-Aryan Group*.—The earliest accessible form of Aryan speech in India is the *Vedic*, especially the language of the sacred hymns of the Rigveda which represent the Aryan tribes as settled in the Punjab. Even at that early period dialectic varieties seem already to have existed to some extent among different tribes. In the course of the later Vedic ages the Aryan language extended its sway eastward over nearly the whole of northern India. During this process foreign ethnic elements were doubtless largely absorbed by the Aryan community, and the greater or less proportion of such admixtures, coupled with independent political formations, could not fail ere long to produce different dialects of marked individuality. Meanwhile, the exegesis of the sacred hymns, already largely unintelligible at the time when they were first collected, and the consequent close cultivation of grammatical and phonetic studies, resulted in the grammatical fixation of the literary language (hence called *Sanskrit*—i.e. 'completely or correctly formed, polished'), probably about the 6th century B.C. Henceforth the divorce between the literary idiom and the popular dialects was complete. The existence of such dialects at that time is amply attested by the fact that Gautama S'akyamuni (or Buddha, 'the awakened,' as he subsequently called himself), in preaching his new gospel of salvation through individual righteousness, made use of the Magadhi, commonly called *Pali*, the local dialect of his native Magadha (Behar), which accordingly became the sacred language of Buddhist literature; but being as such a grammatically fixed idiom, like the Sanskrit, it became gradually estranged from the vernacular with which it had originally been identical. The canonical books of the Buddhists were settled at a council held in the reign of the Emperor As'oka about 250 B.C., but they were not committed to writing till about 80 B.C., so that the state of their language is attested for that period at latest. The same Emperor As'oka has, however, left us authentic dialectic documents of his own time—viz. the famous rock inscriptions, containing religious edicts, and scattered over the area of northern India from the vicinity of Peshawar on the north-west frontier, and Girnar in Gujarat, to Cuttaek on the eastern coast. Similar in its origin to the Pali, another local dialect, the *Maharashtri*, or language of the province of Maharashtra (the present Malhatta country), became the religious dialect of another large sect, the Jains, which seems to go back to about the same time as the origin of Buddhism. Moreover, several popular dialects were early employed for literary purposes by Indian dramatists. While the use of Sanskrit in dramatic literature is confined to male characters of the higher classes, women and inferior male characters are invariably made to speak various local dialects. These dialects, called *Prakrits*—i.e. either 'vulgar' or 'derived (from the Sanskrit)'—may be looked upon as the forerunners of the modern vernaculars of northern India. Though the oldest existing plays can hardly be placed earlier than the 6th century of our era, the actual use of the Prakrits, as popularly spoken

dialects, may go back some centuries before that time. The principal *Neo-Aryan* languages of India are (1) *Bengali*; (2) *Urjju* (of Orissa); (3) *Hindi* (of the Upper Provinces), with the closely allied *Punjabi* and *Nepali* (the language of the Goorkhas, the ruling class of Nepal); (4) *Sindhi* (on the lower Indus); (5) *Kashmiri*; (6) *Marathi*; (7) *Gujarati*—which Beames (*Comparative Grammar of the Modern Aryan Languages of India*), however, takes to be a mere dialect of Hindi. To these may be added (8) *Assamese*, formerly considered a dialect of Bengali; (9) *Brahui*, one of the two languages spoken in Beluchistan, which at one time was thought to be Dravidian, whilst some scholars would even now refer it to the Kolarian group; and (10) *Sinhalese*, the language of the southern half (perhaps at one time of the whole) of the island of Ceylon, doubtless imported from northern India, in the early centuries B.C., by Buddhist immigrants; with its literary dialect called Elu, and the dialect of the Aryanised aboriginal Veddahs.

Many of these languages show a considerable number of dialectic varieties, especially the Hindi, by far the most important of all, of which as many as fifty-nine dialects are enumerated by Curt (*Modern Languages of the East Indies*). Not a few of these dialects are, however, of a very mixed character, owing to their being spoken by Aryanised tribes of one of the three other groups, and consequently showing a more or less strong non-Aryan element. A peculiar and important form (for it can scarcely be called a distinct dialect) of Hindi is *Urdu* or *Hindustani*, which, being Hindi, with a more or less considerable admixture of Persian (and Arabic) words, and written in the Persian character, originated, after the Mohammedan conquest, through the official intercourse of the Persian-speaking rulers and their Hindu subjects—much as in English the original Teutonic groundwork has been overlaid by a thick layer of Romance and Latin vocables and formative elements—and has developed into a kind of *lingua franca* for the whole of India; a southern variety of it being called *Dakhani* or *Dekhani*. In point of the antiquity of its literary documents, Sinhalese stands pre-eminent among Neo-Aryan languages; its development from, or by the side of, Pali being well authenticated by Elu works going back to the 5th century of our era, and by inscriptions of very early date. Next to it comes Hindi, commencing, about 1200 A.D., with the Prithiraj Rasau, a heroic poem by Chand Bardai, composed in an archaic form of Hindi which Trumpp proposes to call 'Old Hindi;' whilst the term 'Hindu' is applied by him to a somewhat more modern form, represented by the writings of the religious reformer Kabir (c. 1450 A.D.), the sacred books of the Sikhs (the Granth), and Talsi Das's translation of the Sanskrit epic Ramayana. In Marathi the oldest existing work, a paraphrase of the Sanskrit philosophical poem Bhagavadgita, claims to have been written in 1290 A.D.; whilst Bengali literature commences with the religious writings of the Vaishnava reformer Chaitanya, a contemporary of Luther. None of the other languages possess any literature above two or three centuries old.

(2) *Dravidian Group*.—The extension of the Brahmanical civilisation and literature has introduced into these languages, as into those of the other stocks, a very considerable element of Sanskritic words; whilst their grammatical structure has, on the whole, remained intact. As regards the ultimate affinities of this stock, Dr Caldwell, in his *Comparative Grammar of the Dravidian Languages*, has shown that Dravidian speech, in its formative features, betrays a 'family likeness' to the Scythic (Finnic-Tataric) stock; whilst he

also detects in it certain analogies, though of a rather indefinite and remote character, to Aryan speech. The people speaking Dravidian languages occupy a compact area extending over the whole of the southern part of the peninsula, with one or two enclaves in the Aryan territory. Dravidian scholars recognise twelve distinct languages, only four of which, also the most important in regard to population, have developed anything worthy of the name of a literature—viz. (1) *Tamil*, occupying the south-eastern; (2) *Telugu*, the north-western; (3) *Kanarese* (or *Kannada*, i.e. Karnataka), the north-eastern; and (4) *Malayalam*, the south-western portion of the Dravidian area. The remaining members of the family are (5) *Tulu*, between the two preceding ones, on the Malabar coast; (6) *Kodagu*, the language of Coorg, adjoining the last named, inland; (7) *Tulu* and (8) *Kota*, both spoken by tribes of the Nilgiri hills; (9) *Gond*, in Central India; (10) *Khond* and (11) *Oráon*, west and north-west of Orissa; and (12) *Rajmahal*, or *Máler*, the language of a tribe of the Rajmahal hills in Bengal. Tamil, which has also extended its sway over the northern half of Ceylon, may boast of a rich and varied literature; its oldest works—the Chintámáni, an epic poem of 15,000 lines, and the Kural, a collection of ethical stanzas, both of them by Jain poets—probably dating back to the 10th century, if not earlier. In the sister languages, Nannaya's Telugu translation of the epic Mahábháráta and Kes'ava's Kanarese grammar probably belong to the 12th century; whilst Malayalam, originally a mere dialect of Tamil, commences with the heroic poem Rámácharita, of uncertain date, but probably a century or two later than those works.

(3) *Kolarian Group*.—The term, derived from the tribal name of the Kols, was first introduced by Sir G. Campbell. The people speaking these languages, settled chiefly in the jungly and mountainous tracts of the Central Provinces, are computed to number about two million, though many tribes, such as the Bhils, who have adopted other languages, especially Hindi, ethnologically doubtless belong to this group. Kolarian speech possesses a very complete suffixal system of inflection, its conjugational system being especially developed. Some of the chief points in which it differs from Dravidian speech are that it has a dual number for nouns, and that it lacks a negative form of the verb. Our knowledge of most of these languages is, however, still sadly defective. Brandreth proposes to include nine different languages under this group, to which Cust adds a tenth; but this scheme is so far only provisional. The best-known member of this family is the *Santali*—spoken by a vigorous tribe inhabiting the so-called Santal Parganas (and adjoining districts) along the western frontier of Lower Bengal—of which we have a good grammar by Skrefsrud (1873). The only other language of this group the grammar of which has been at all adequately treated is the *Mundari*, spoken by Mundas, Bhumij, and Larka Kols; whilst of others, which are probably destined to die out before long, we have as yet only scanty vocabularies.

(4) *Tibeto-Burman Group*.—This field has also as yet been very imperfectly surveyed, most of its languages lying either wholly beyond the Indian frontier, or only just projecting into the British territory. They share the general agglutinative character of the only two literary languages of this family, the Tibetan and Burmese, whilst in them the tone of the voice also plays generally an important part in the meaning of words, though not to the same extent as in monosyllabic languages. Brandreth proposes to arrange these border-languages in nineteen different classes, which Cust re-

duces to a few geographical groups—viz. the Nepal, Sikkim, Assam, Manipur-Chittagong, and Trans-Himalayan groups—the last-named group consisting of the southern offshoots of the Tibetan branch of Tibeto-Burman speech.

A curious cluster of dialects, which seems to be independent of any of the four groups of Indian speech hitherto mentioned, is found in the Khási hills, in the province of Assam. There is a good *Khási* grammar by Pryse. This language, in which five or six dialects are distinguished, is of the monosyllabic order; but its exact relationship has not yet been determined.

The word Hindu has been used in various senses. In truth it means all those who profess the Hindu or Brahmaic faith, which, however, consists of many sects. This vast community of nearly 208 millions of souls is divided into several Castes (q.v.), high and low. The high castes are mainly Aryan; the lower castes partly Aryan and partly Dravidian or aboriginal. A person must be born into the high castes, and cannot enter them by conversion. If a person, as for instance an aboriginal, be converted, he can enter the lower castes only. The sections of Hindu community thus summarised differ not only in nationality and language in different provinces, but in customs and dress. Their languages are to be counted by scores.

The Mohammedan (or, strictly, Muhammadan) population, on the other hand (about 58 millions), in all parts of India affect the same customs, and generally speak one language—Hindustani or Urdu. It is the one chiefly known to Europeans. It is the vernacular in the towns alone, and those, too, of the north-west only. In these provinces, also, it is the official language. It is, however, hardly known to the Mohammedans of eastern Bengal, who speak Bengali. Persian and Arabic are more or less known as classical languages to the Mohammedans of India, but are not spoken. The language of the courts of justice is everywhere the language of the province.

The aboriginal hill-tribes have caused trouble on the Assam frontier at various times, especially those on the north-east frontier near Assam. The hill-tribes of the Dravidian race also are in a primitive state socially. Of these the most important are the Bhils and Gonds, who are found in the Vindhya and Satpura regions, the Khonds and Kols, who inhabit the Eastern Ghats, and the Sontals on the hill-country west of Bengal. The Bhils were wont to live by plunder, and used to burst out of their jungles, committing many outrages; but in 1825, after various methods of subduing them had been unsuccessfully tried by the British government, it was resolved to tempt them into military service, with good results. The Khonds and Kols, driven into the jungles and mountains of Central India by the advance of the Aryan race from the north-west, have preserved the grim religion that prevailed in the country before Hinduism was heard of. That religion may be briefly characterised as Devil-worship, with efforts to propitiate the malignant deities by human sacrifice, principally of children. Successful efforts have been made by the British government to suppress these practices. As a tribe the Gonds are the strongest; they adopted parts of both Hindu and Mohammedan culture, founded a rude dynasty, and signalled their rule by works of material improvement. For more than a century past they have relapsed into their pristine condition. It is from among these aboriginal tribes, numbering in all perhaps fifteen millions, that proselytes to Hinduism are obtained.

National Character.—To the inhabitants of India, who, although generally a mixed race of Dravidian

and Aryan origin, now form many distinct nations, no general statement can apply. The acute but unwarlike inhabitants of the Gangetic delta are quite unlike the less intellectual but sturdier races of the upper basins of the Ganges and the Indus—i.e. the North-western Provinces and the Punjab. These latter again are dissimilar from the high-bred and chivalrous race of Rajasthan or Rajputana, and the hardy though humble Mahratta of the Western Ghâts. Still further varieties are found in the half-warlike and partly refined races of the eastern coast and southern peninsula, mixed up with races of lesser spirit and culture. The races who in this generation are believed to have political aspirations are the Sikhs of the Punjab—the Sikh faith being really an offshoot of Hinduism—the Goorkhas of Nepal, and the Mahrattas of the Western Ghâts; and perhaps some sections of Mohammedans, who might be aided by Arabs immigrating from Arabia. The Brahmans everywhere, to whatever nationality they may belong, or whatever language they may speak, have a homogeneous character, imbued with a lofty pride transmitted through long generations.

The Mohammedans of central Asiatic descent are strict adherents of their faith, and sometimes fanatical. But those who, like the inhabitants of eastern Bengal and of parts of the Punjab, are merely Hindus or aborigines made Mohammedans by conversion, are of course less orthodox. Their religion is a mixture of the doctrines of the Koran with the local idolatry. The Parsees, a mercantile and educated class, seated at Bombay and along the west coast of India, are the descendants of the fugitive fire-worshippers of Persia. See PARSEES.

The national character cannot be portrayed from this congeries of nationalities, yet some characteristics can be set forth as generally prevalent: for the upper and middle classes, domestic affection, munificence, tenacious adherence to custom, veneration with awe leading to superstition, love of external nature, an inclination for abstract meditation, mental acuteness and subtlety, litigiousness, shrewdness of observation; for the humbler classes, temperance, patience, docility, charitableness to the indigent, endurance, fortitude under disaster, and industry. The qualities termed principle and public spirit in western phrase cannot be predicated of any class. Deep attachment to the ancestral religion takes the place of patriotism. 'Dharma' to the Hindu, and Din to the Mohammedan, means virtue under a religious sanction. In justice to the women, it must be said that, despite their subjection and seclusion, they have shown courageous fortitude in times of danger and charitable munificence when endowed with means. The suttee 'widow-burning' evinced supreme resolution. Predatory and pugnacious instincts, hereditary in some classes, are partly subdued by the *pacifomania* of British rule. Politically the leading factor is this, that the congeries of nationalities, despite community of faith, have no idea of national union or of self-organisation. This renders them comparatively easy of government by a foreign power that possesses governing capacity.

Physical Qualities.—These vary together with race and climate. The stature is often tall in the north, and short in the south very much as in Europe. Strength does not depend on height, of course. The Nepàlese are short, so are the Mahrattas; both are strong. As a rule, strength with courage is found more in the north than in the south, but least perhaps in the Gangetic delta. Bengal is the only large province that furnishes no recruits to the army. Physical endurance, the power of making protracted bodily exertion with but scanty sustenance, is perceptible everywhere;

in some places it is extraordinary, and rarely to be equalled in any country. As a point of comparison, a native has hardly half the strength or nervous force of a European, perhaps not more than one-third; his work comparatively would be in the same proportion. In consequence of this and of the cheapness of living, his wages are not more than one-sixth of the British rate. A proposition of this sort cannot be stated accurately or definitely, but some such truth as this lies at the basis of the political economy of the country.

Religion.—Hinduism or Brahmanism is the religion of the great majority of the people, and Mohammedanism comes next. Of the 287,000,000 inhabitants of India, British and feudatory, in 1891, 207,700,000 were Hindus, 57,000,000 Mohammedans, 9,300,000 aboriginal pagans, 7,000,000 Buddhists (almost all in Burma), 1,400,000 Jains, 90,000 Parsees (chiefly in Bombay), 17,000 Jews. In Bengal there are nearly 24,000,000 Mohammedans to 47,000,000 Hindus; in the Punjab, 13,000,000 to 10,000,000 Hindus. The Sikh religion is professed, according to the census for the Punjab, by 1,900,000 of its inhabitants. The Christians number 2,200,000. Buddhism at one period prevailed very generally throughout India; it is now confined to Bhutan, Sikkim, and Burma. See BUDDHISM, JAINS, MOHAMMED, PARSEES, SIKHS.

Hinduism.—The first to be considered is that variety of creeds which is derived from Brahmanic sources, and known as the Hindu religion, or Hinduism. The following summary of the origin and development of Hinduism is from Goldstücker's essay (*Literary Remains*, 1879), originally written for the first edition of this work.

Hinduism may be divided into three periods, the Vedic, Epic, and Purānic, as our knowledge of the first is derived from the sacred books called the *Vedas*, of the second from the epic poems the *Ramayana* and the *Mahabharata*, of the third from the mythological works known under the name of *Puranas* and *Tantras*. Writers on this subject have marked the beginnings of certain divisions of Vedic works with 1200, 1000, 800, and 600 years B.C. The question of Hindu chronology will be more particularly considered in the article VEDA. Probably the latest writings of the Vedic class are not more recent than the 2d century B.C. Uncertainty hangs over the period at which the two great epic poems were composed, although there is reason to surmise that the lower limits of that period are not far from the beginning of the Christian era. The Purānic period, on the other hand, all scholars are agreed to regard as corresponding with part of our medieval history.

The Vedas.—If the *Rig-Veda* the oldest of the Vedas, and probably the oldest literary document in existence—coincided with the beginning of Hindu civilisation, the popular creed of the Hindus, as depicted in some of its hymns, would reveal the original creed not only of this nation, but also of humanity itself. The Hindus, as depicted in these hymns, are far advanced beyond the starting-point of human society. Indeed they may be ranked among these communities already experienced in arts, defending their homes and property in organised warfare, acquainted even with many vices which only occur in an advanced condition of artificial life (see VEDA). Yet the ideas expressed in the greatest number of the *Rig-Veda* hymns are neither emanating from an artificial imagination nor largely affected by philosophy. The Hindu of these hymns is engrossed by the might of the elements. The powers which turn his awe into pious subjection are: *Agni*, the fire of the sun and lightning; *Indra*, the bright, cloudless firmament; the *Maruts*, or winds; *Sūrya*, the sun; *Ushas*, the dawn; and nature in general. He

invokes them, not as representatives of a superior being, before whom the human soul professes its humility, but because he wants their assistance against enemies—because he wishes to obtain from them rain, food, cattle, health, and other worldly goods. He seeks them, not for his spiritual, but for his material welfare. Sin and evil, indeed, are often adverted to, and the gods are praised because they destroy sinners and evildoers. But these words are not to be associated with our notions of wrong. A sinner, in these hymns, is a man who fails to address praises to those elemental deities, or to gratify them with the oblations they receive at the hands of the believer. He is the foe, the robber, the demon—in short, the borderer infesting the territory of the 'pious' man, who, in his turn, injures and kills the other. On the whole these hymns, so far from reflecting unfavourably on the internal condition of the Hindu community, seem, on the contrary, to bespeak the union and brotherhood which existed among its members.

The worship of the elementary beings was originally simple and harmless. Most of the Rig-Veda hymns mention but one sort of offering made to these gods. It consists of the juice of the Soma (q.v.) or moon-plant, which, expressed and fermented, was an exhilarating and inebriating beverage. There is a class of hymns, however, to be found in the Rig-Veda in which the instinctive utterance of feeling makes room for the language of speculation; and the mysteries of nature being more keenly felt, the circle of beings which overawe the popular mind becomes enlarged. Thus, the objects by which Indra, Agni, and the other deities are propitiated, become gods themselves; Soma is invoked as the bestower of all worldly boons. The animal sacrifice is added to the original rites; and the horse of the sacrifice especially is invoked by the worshipper.

Mystical language then shows that religion was endeavouring to penetrate into the mysteries of creation. This longing is expressed in other hymns, which mark the beginning of the *philosophical creed of the Vedic period*. The following extract will illustrate the nature of this third class of hymns, as they occur in the oldest Veda: 'Then there was no entity or non-entity; no world, or sky, or aught above it; nor water deep or dangerous. Death was not, nor was there immortality, nor distinction of day or night. But THAT breathed without allation, single with her who is within him. Other than him, nothing existed which since has been. . . . Who knows exactly, and who shall in this world declare, whence and why this creation took place? The gods are subsequent to the production of this world; then who can know whence it proceeded, or whence this varied world arose, or whether it uphold itself or not? He who in the highest heaven is the ruler of this universe, does indeed know; but not another one can possess this knowledge.'

As soon as the problem implied by passages like these was raised, Hinduism must have ceased to be the pure worship of the elementary powers. Henceforward, therefore, we see it struggling to reconcile the latter with the idea of one supreme being. The first of these efforts is shown in that portion of the Vedas called *Brahmana*, the second in the writings termed *Upanishad*. In the *Brahmanas* the mystical allegories are reduced to a systematic form. Epithets given by the Rig-Veda poets to the elementary gods are spun out into legends. A ponderous ritual, founded on those legends, is brought into a system which requires a class of priests. However much this ritual betrays the gradual development of the institution of castes (unknown to the hymns of the Rig-Veda), there are still two features in them

which mark a progress of the religious mind of the ancient Hindus. While the poets of the Rig-Veda are chiefly concerned in glorifying the visible manifestations of the elementary gods, in the Brahmanas their ethical qualities are put forward for imitation and praise. Truth and untruth, right and wrong—in the moral sense which these words imply—are often emphasised in the description of the battles fought between gods and demons. A second feature is the tendency in these Brahmanas to determine the rank of the gods, and to give prominence to one special god amongst the rest; whereas in the old Vedic poetry, though there may be a predilection to bestow more praise on some gods than on others, yet there is no intention to raise any of them to a supreme rank. Thus, in some Brahmanas *Indra*, the god of the firmament, is endowed with the dignity of a ruler of the gods; in others the sun receives the attributes of superiority.

The Upanishads.—An answer to the question regarding the Almighty is attempted by the 'mysterious doctrine,' as laid down in the writings known under the name of *Upanishads*. Their object is to explain, not only the process of creation, but also the nature of a supreme being, and its relation to the human soul. In the Upanishads the deities of the Vedic hymns become symbols to assist the mind in an attempt to understand the true nature of one absolute entity, and the manner in which it manifests itself in its worldly form. The human soul itself is of the same nature as this supreme or great soul; its ultimate destination is that of becoming reunited with the supreme soul, and the means of attaining that end is not the performance of sacrificial rites, but the comprehension of its own self and of the great soul. Thus the Upanishads became the basis of a comparatively enlightened faith. They contain the germs whence the three great systems of Hindu philosophy arose. They advance sufficiently far to express belief in a supreme being, but acknowledge the inability of the human mind to comprehend its essence. See VEDA.

The Epics and the Philosophy.—The Epic period of Hinduism is marked by a development of the two creeds, the general features of which have now been traced in the Vedic writings. The popular creed strives to find a centre round which to group its imaginary gods, whereas the philosophical creed finds its expression in the groundworks of the *Saikhya*, *Nyaya*, and *Vedanta* systems of philosophy. In the former we find two gods in particular who are rising to the highest rank, Vishnu and Siva; for as to Brahmā (the masculine form of Brahman), though he was looked upon now and then as superior to both, he gradually disappears, and becomes merged into the philosophical Brahma (the neuter form of the same word), which is a further evolution of the great soul of the Upanishads. In the epos *Ramayana*, the superiority of Vishnu is admitted without dispute; in the great epos, the *Mahabharata*, however—which, unlike the former epos, is the product of successive ages, there is an apparent rivalry between the claims of Vishnu and Siva to occupy the highest rank in the pantheon. Already there is a predilection during this Epic period for the supremacy of Vishnu; and the policy of incorporating rather than combating antagonistic creeds led more to a quiet admission than to a warm support of Siva's claims to the highest rank. One remarkable myth illustrates the altered position of the gods during the Epic period. In the Vedic hymns the immortality of the gods is never matter of doubt. The offerings they receive may add to their comfort and strength, but are not indispensable for their existence. It is, on the contrary, the pious sacrificer himself who, through his offerings,

secures to himself long life and immortality afterwards. And the same notion prevails throughout the oldest Brahmanas. It is only in the latest work of this class, and more especially in the Epic poems, that we find the inferior gods as mortal in the beginning, and as becoming immortal through exterior agency. In the *Satapatha-Brahmana* the juice of the Soma plant, offered by the worshipper, or at another time clarified butter, or even animal sacrifices, impart to them this immortality. At the Epic period Vishnu teaches them how to obtain the *Amrita*, or beverage of immortality, without which they would go to destruction.

The philosophical creed of this period develops the notion that the union of the individual soul with the supreme spirit may be aided by penances, such as peculiar modes of breathing, particular postures, protracted fasting, and the like; in short, by those practices which are systematised by the Yoga doctrine. The most remarkable Epic work which inculcates this doctrine is the celebrated poem *Bhagavadgita*, which S'ankara, the great philosopher, declared to be founded on the Yoga belief. The doctrine of the reunion of the individual soul with the supreme soul was necessarily founded on the assumption that the former must have become free from all guilt affecting its purity before it can be remerged into the source whence it proceeded. And, since one human life is apparently too short for enabling the soul to attain thereto, the Hindu mind concluded that the soul, after the death of its temporary owner, had to be born again, in order to complete the work it had left undone in its previous existence. This is the Hindu doctrine of *metempsychosis*. The beginning of this doctrine may be discovered in some of the oldest Upanishads, but its fantastical development belongs to the Epic time.

The Puranas and the Tantras.—The Puranic period of Hinduism is that of its decline, so far as the popular creed is concerned. Its pantheon is nominally the same as that of the Epic period. Brahma, Vishnu, and Siva remain still at the head of its imaginary gods. But whereas the Epic time is generally characterised by a friendly harmony between the higher occupants of the divine spheres, the Puranic period shows discord and destruction of the original ideas whence the Epic gods arose. Brahma is withdrawn from the popular adoration, leaving Vishnu and Siva to fight their battles in the minds of their worshippers for the highest rank. The divine element which still distinguishes these gods in the *Ramayana* and *Mahabharata* is now more and more mixed up with worldly concerns and interseated with historical events, disfigured in their turn to suit individual interests. Of the ideas implied by the Vedic rites scarcely a trace is visible in the Puranas and Tantras, which are the textbooks of this creed. Some Puranas, it is true—e.g. the *Bhagavata*—make in some sense an exception to this aberration from original Hinduism; but they are a compromise between the popular creed and the Vedanta creed, which latter remains the faith of the educated and intelligent. They do not affect the worship of the masses as practised by the various sects, whether harmless, as with the worshippers of Vishnu, or offensive, as with the adorers of Siva and his wife Durga. It is this popular creed which, with further deteriorations caused by the lapse of centuries, is still the main religion of the masses in India. See PURANA and SANSKRIT, Vol. IX. p. 153.

The philosophical creed of this period, which is still preserved by the educated classes, is derived from the Vedanta philosophy. It is based on the belief of one supreme being, who is invested with all the perfection conceivable by the human mind. But the nature of that being is declared to be

beyond the reach of thought, as not possessing any of the qualities by which the human mind is able to comprehend intellectual or material entity. See VEDANTA.

The sects which arose during the third period of Hinduism suppose that their worship is countenanced by the Vedas; but its real origin is derived from the *Puranas* and *Tantras*. There are three chief divisions of these sects—the adorers of Vishnu (Vaishnavas), of Siva (Saivas), and of the wives or female energies of these gods (Saktas). For the philosophy, literature, &c., see SANSKRIT.

The Popular Faith.—This must be noted as it is seen among the Hindus to-day. The trial of Brahma the creator, Vishnu the preserver, and Siva the destroyer is still remembered. One of them (Brahma) has lapsed into an abstraction, and practical adoration is divided between the other two. The Sivaïtes are chiefly, but not entirely, in the north; the Vishnuïtes in the south. The Sivaïte worship is chiefly attracted by the wife of Siva, under various names—Kali, Durga, Parvati, and so forth. Vishnu, again, is almost lost in the worship paid to his two incarnations (avatars), Rama and Krishna. Lesser divinities, such as Hanuman, the 'monkey-god,' and Ganesh, the 'elephant-god,' are also honoured. The sanctity of the Ganges (Ganga) remains, and when the river is lost in the delta that sanctity is to some extent continued to the Hooghly, flowing past Calcutta. The Nerubudda also is sacred. The ling or phallus is still an emblem, and gives its name to the Lingayet sect in the Deccan. It is hard to gauge the thoughts of Hindus regarding a future state. They think of a heaven (Svarga) and a hell; also of giant demons (Rakshas). From their demeanour in the presence of certain death it may be inferred that they expect absorption into the divine essence or entity, through the intervention of the god or gods they have worshipped. It is hard to measure the extent to which this faith may have been weakened by the western education of to-day in the minds of the rising generation. The undermining is, however, extensive. Still, in the upper class there are many who cling to Brahmanic orthodoxy, and with the mass of the people the adoration at the temples, the floral and votive offerings, the ceremonies, the festivals, the pilgrimages, are all maintained. The rule of life is still comprehended in the term Dharma, which includes religious fidelity and moral virtue.

The Caste System, which is a potent factor in the national life, does not appear to have been a part of the Vedic religion originally. But it arose subsequently with a religious sanction which is still maintained. The Brahman caste, including the priests, is held to have something divine in it. Most of the several millions of Brahmans follow secular employment; but even the humblest of them is hedged round by a certain sort of sacredness. This caste, together with the Kshatri or warrior caste, and the Vaisya or trader caste (including the subdivision of Kayasths or writers), are held to be twice-born (dwija). This character does not attach to the Sudra caste, which includes the masses. The restrictions in respect of food and drink (water) in the caste system are most severe and narrow. Caste is lost from any of the infringements that are inevitable in foreign intercourse. But restoration to caste, though often expensive, is sufficiently facile. Within each caste as a division of the people there are subdivisions infinitely numerous, which as a whole have been reckoned at several thousands.

The Brahmans.—But a new religion is arising among the Hindus educated after the western manner: this may be termed Brahmoism or

theism, eschewing caste and almost everything Brahmanic. There are already two divisions—Brahmos and Adhi-Brahmos; perhaps other divisions may be formed. Their community is termed the Brahmo Somaj (q.v.). These theistic reformers look primarily to the Vedas, but refer also to the Christian Bible. This intellectual, moral, and spiritual movement may have infinite development under the national education now established, and is to be reckoned among the phenomena of the country. It has been necessary to pass a special law for the marriages of this sect and other sects.

The Sikhs.—Their faith, though not quite what it was in the preceding generation, is still a living power. In the Punjab and the protected Sikh states it really was a sort of reformation, and a moral system engrafted on Brahmanism. Otherwise it recognises all, or nearly all, the Brahmanic tenets, caste included. Its sacred book, the Granth, is well known. Its spiritual teachers (Gurus) have a status irrespective of the Brahman priesthood, and it has religious orders endowed with fighting qualities. A man is not born into its system, but is initiated. Practically the initiated ones are all Hindus, who thus become Sikhs or disciples. There are two modes of initiation, something like baptism: the first, that of the foot, practised by the founder, Baba Nanak; the second, that of the sword, as practised by Govind Sing, the warlike propagator. The former has more of a religious character, the second is more militant. The popularity of the latter enlivened in the palmy days of the Sikh kingdom, when the temple of initiation at Amritsar, near Lahore, was daily crowded.

Buddhism is now for the people only a *nomine umbra*; probably the words 'buddh,' as abstract wisdom, and 'nirvāna,' as a haven of celestial quiescence, are remembered. In the Eastern Himalayas, Sikkim, and Bhutan it is really Lamaism (q.v.), or the medieval corruption of Buddhism, of which the headquarters are at Lhasa, in Tibet, with the Dalai Lama and the incarnations. The representations of Buddha or Gautama have the aspect of ineffable repose which Buddhism has everywhere exhibited. The caste system does not exist, but the monastic order is all-powerful. In Burma the faith is still mainly that which was settled at the last great council of Asoka, in northern India, before the Christian era. Here also caste is not acknowledged; but the priestly and monastic orders, though they cannot arrogate a status like Brahmins, are very influential.

Jainism is believed to have originally sprung from the same school of speculative thought as Buddhism. It has sacred books and saints of its own, in a long line or series, and it promises a future quiescence hardly distinguishable from annihilation. It has an excessive tenderness for animal life. It recognises caste. Its adherents are largely found in the banking and mercantile classes.

Mohammedanism.—This is, in many parts of the country, strict and exactly preserved, and 'din,' or orthodoxy, is still a word to conjure with. The two sects, Sunnis and Shiāhs, exist in this as in other countries; the dynasties have been mostly Sunni, and the people chiefly belong to that sect, but the Shiāhs have always been numerous at Lucknow. In eastern Bengal, however, the faith is much modified and debased, and this remark applies to nearly half of the Moslem population. The ramifications of the fanatical Wahabi sect in Arabia have spread to the Indian empire, thereby causing occasionally political trouble.

The Parsees preserve the Zoroastrian faith and practice—the fire-worship, and so forth. Their

towers of silence, inside of which the dead are deposited, are conspicuous objects. There are traces still in India of the old worship of trees—the Bo, the tulsi, and others, and of the serpent (Naga). The aboriginal cult consists of veneration for the great spirit and for malignant powers, including smallpox, and even the tiger, with worship of stocks and stones.

Religious Endowments. The several religions have from time immemorial received endowments from the native dynasties, which endowments are in part maintained under British rule. The value of these endowments consisted in the alienation of the land revenue in favour of religious institutions as grantees. The government has severed itself from any share in the management of these institutions, but it regards the landed endowments as property, and has maintained them after due investigation of tenure, title, and the like.

Christianity.—The traditions of St Thomas (q.v.) the Apostle survive in the south, where also a Syrian Church was planted in the early centuries after Christ. In the 5th century Nestorianism came from Babylon, and still survives. In the 16th century Roman Catholic missions arrived from Portugal, and soon afterwards came the famous St Francis Xavier (q.v.) with the Jesuits. The Jesuit missions had great success on both sides of the Peninsula in a certain way, but their ministers were somewhat orientalised. Just two centuries later—i.e. at the middle of the 18th century—the Society of Jesus was broken up in Europe, and the south-Indian missions languished in consequence. Early in the 19th century the society was re-established, and ere long its missions were resuscitated.

The Danish settlement on the south-east coast at Tranquebar saw the first Protestant mission, which was Lutheran, under Ziegenbalg, in 1795. He was followed by Schwartz in the Peninsula. Towards the end of the century the Baptist mission was set up at the then Danish settlement at Serampore. In the early years of the 19th century Henry Martyn, the Church of England chaplain, began to work as a missionary. The bishopric of Calcutta was established in 1814, and then followed the operations of the two great associations of the Church of England—the Church Missionary Society and the Society for the Propagation of the Gospel. The Church of Scotland began its missions in 1830, increased by the Free Church after 1843. These were followed by missions from the Wesleyan and Baptist communities (British and American), from the German Society at Basel, from the London Missionary Society, and the United Presbyterians in 1860. In 1835-37 the bishoprics of Madras and Bombay were established, the Bishop of Calcutta becoming Metropolitan. Recently bishops have been appointed for the Punjab and Sind, and for Burma, besides two missionary bishops for the Peninsula. The Church of England is the official church, and its chaplains are stationed at the principal towns and military cantonments. In many places also there are ministers of other denominations. Roman Catholic priests are ministering everywhere, and many of them are salaried by the government as ministers to the European soldiers of their faith. Besides these there are the European ordained missionaries—many hundreds of all denominations—and under these a fast growing native ministry.

The following was the distribution of the Christian population, by race, in the empire in 1881: European, 142,610; Eurasian, 62,085; Native, 893,658; others (including various Asiatic races), 764,172—total, 1,862,525. The following is accord-

ing to denomination at the census of 1891: Church of England, 295,016; Presbyterians, 40,407; other Protestants, 360,905; Roman Catholics, 1,315,263; Syrians, Armenians, and Greeks, 201,684—total, 2,284,380.

The missionaries have now, for half a century, worked with pastoral devotion, literary labour, and educational efficiency, in western as well as eastern knowledge. They have studied religions, translated the Scriptures into the principal languages, issued numerous works on Christian teaching, supervised schools, founded colleges, managed the cure of congregations. They have long constituted a moral force in the country, with beneficial effect, socially and politically. The increase in the number of native Christians has been proportionally great.

Social Customs.—Four-fifths of the population are affected largely by the caste system already described as being partly at least connected with the popular religion. A religious sanction in some degree attaches to infant marriage, or child marriage, with all classes; also to the seclusion of women, and to the prohibition against re-marriage of widows, with the upper and middle classes. In practice the women of the masses are not secluded, but, on the contrary, appear everywhere, and work out of doors; they re-marry, too, if in widowhood. The burning of widows (suttee or sati) on the funeral pyres of their husbands has long been suppressed by the criminal law under British rule. Polyandry is found only among a few of the aboriginal tribes. Polygamy is sanctioned, but not enjoined; it is, of course, confined to those who can afford to maintain more than one wife. Here, again, in practice the masses of the people are monogamist. In all classes the marriage expenses, arising chiefly from the offerings made to the priesthood, are so excessive as frequently to cause embarrassment to families. Many of the social customs above indicated are regretted and deprecated by native reformers as being injurious to the national progress, and benevolent efforts for reformation are made. The laws of inheritance, dower and divorce, women's property, adoption, partition, and other social matters are held to have a quasi-religious sanction. They are generally observed in the courts of justice under British rule, both for Hindus and Mohammedans. Three criminal practices have been severely dealt with by the British government: female infanticide, arising from the presumed exigencies of caste; the murderous and treacherous Thuggee connected with the goddess of destruction; and the Meriah or human sacrifices by some of the hill-tribes.

The Village System.—This is a factor in the rural life of the Hindus, and from them has been adopted by the Mohammedans. A village does not merely mean a collection of houses, but corresponds to a township or a parish. It is an area of some hundreds or thousands of acres of land, according to circumstances, and is under the administration of hereditary functionaries, the principal of whom is the *potail* (head-inhabitant), a small local magistrate, who superintends the affairs of the community, settles disputes, attends to the rural police and the collection of taxes. Among the other functionaries may be mentioned the accountant and notary (*Kurani* or *patwari*), who keeps a register of the produce and the names of the proprietors, and draws up all deeds of sale, transfer, &c.; the Brahman, or village priest; the schoolmaster; and the watchman. Besides these almost every village has its astrologer, smith, carpenter, potter, barber, and bard, all of whom are rewarded out of the produce of the village lands. Under this simple form of municipal government the inhabitants of the country have lived from time immemorial.

The boundaries of the village have been but seldom altered; and though the villages themselves have been sometimes altered, and even desolated by war, famine, and disease, the same name, the same limits, and even the same families, have continued for ages. The inhabitants give themselves no trouble about the breaking up and division of kingdoms; while the village remains entire they care not to what power it is transferred, or to what sovereign it devolves: its internal economy remains unchanged; the potail is still the head-inhabitant, and still acts as the petty magistrate.

Costume.—This is in these numerous nationalities characterised universally by the ease, lightness, and looseness common in the East and suitable to the hot climate. But it varies in the many provinces, and, indeed, with every nationality. The turban (*pagri*) has every sort of dimension, from minute neatness to turgid massiveness. The waistband (*dhoti*) extends often below the knee, in which case there is no trouser. Jackets in many styles are common. The women's dress in many respects resembles that of the men. The petticoat is not universal. The head-dress is often extended, so as to hang gracefully down the back. The shoe is not always worn; indeed, the humbler classes are generally barefooted. With them the blanket is often a plaid. The black colours of Europe are seldom seen, but indigo blue is common. Otherwise white, set off by gay margins, and rich scarfs and shawls, is the prevailing colour. As a whole the national dress is picturesque, and a holiday crowd has the appearance of a flower-garden.

Architecture.—This is not generally remarkable in the humbler dwellings. In the Gangetic delta the materials are bamboo and thatch, and the cottages, being covered with creepers, are picturesque. In the north both walls and roofs are of indurated earth, the effect being utterly plain. In the south wood and brick are used. The street architecture in the cities and towns is diversified in a manner conducing to pictorial effect. The Europeans have not invented any style for their buildings, except at Calcutta, where the private houses have a stately architecture suited to the climate. Otherwise for their churches they have adopted the Gothic style, and for their civil structures the leading styles of Europe, with certainly a noble, even magnificent effect at Calcutta and Bombay. At Madras, in Rajputana, and elsewhere, they have used adaptations of the old oriental styles.

The indigenous styles of architecture for many centuries have been the chief ornaments of the land. Their study has been greatly elucidated by the Archeological Survey. They begin with the Buddhist era; for the preceding or Vedic era there are no remains. The best authority regarding them is Fergusson, from whose works the following classification is taken. It must suffice to note the salient points only.

The Hindu Styles.—In the Buddhist architecture the characteristic features are, first, the *Tope* (a corruption of *Stupa*, or 'monumental mound'), encased with masonry, having a superstructure at the top, and corridors round the base, with four entrances marked by gateways, often of great beauty; secondly, the *Lat* or pillar, generally monumental; the *Chaitya* or hall of worship; the *Vihara*, or monastery, with cells for the monks. The two last named are often rock-cut, and thus have an extraordinary interest. One tower only, that of *Buddh Gya* in Behar, has been found, and it is one of the noblest dimensions. Almost all parts of the architecture are adorned with bold yet graceful carvings of men and women, and of animals. In some of the rock-cut chambers or cave-temples are remains of frescoes immensely valuable to the student.

The only living architecture of Buddhism is in the Eastern Himalayas, in Sikkim. There the figures of Buddha are beautifully executed in terracotta; and the monasteries are protected from the snow by umbrella-shaped roofs. In Nepal there is one tapering pagoda in the Burmese style. In Burma the circular dagobas have been developed into the exquisitely tapering pagodas, with gilded surface, and the masonry is set off by wood-carving of the most elaborate description.

In the Jaina architecture the original characteristics were somewhat similar—Jainism and Buddhism being cognate faiths. But simplicity begins to be lost in ornament. Extensive remains are discovered on hill-tops far removed from one another—Parasnath in Bengal, Abu in Rajputana, Sauranj in Kathiawar. There is a disposition to congregate small temples in great number on hill-tops, so as to form, as it were, cities of the gods. The general effect of these, however, is not picturesque. The large towers become rounded and ribbed, with a circular addition something like a rose on the apex, surmounted by a finial, so that the general effect is not unlike a spire. Arches and domes become prominent features. Elaborate ornamentation is introduced into the stone masonry. Pillars and lesser towers of great beauty are erected.

The styles which follow are historically Brahmanic. In the Himalayas there are two styles: one in Cashmere, with Hindu affinities, but with greater simplicity of outline and of detail in gray limestone; the other in Nepal, with Chinese and Burmese affinities, the most striking examples being those of temples built in stories, with sloping roofs, copper-gilt, and projecting eaves; the walls being often of enamelled brickwork, and the wood-carving very rich.

The Dravidian style prevails in the southern peninsula, where the Tamil language is spoken. It is called after the old Dravidian race, which has still a distinctive existence in this region. The towers of the temples lose the rounded and spiral forms, and become nearly pyramidal. The temple enclosures have vast gateways (gopuras) of comparatively square shape, though narrowed towards the top. The surface ornamentation, though very fine in some respects, is on the whole grotesquely profuse. At some points, however, the redstone sculptured figures are superb. Granite is largely employed in this style, also the exquisite stucco obtained from shell-lime. The styles heretofore mentioned were devoted almost entirely to religious purposes. But this Dravidian style is adapted to civil uses, and appears in stately palaces, public offices, pavilions, elephant-stables, and so forth. This has been ascribed to the influence of Mohammedan example. The arch becomes prominent; and at Madura especially there is an arched hall of real magnificence.

The Chalukyan style is named after a Hindu dynasty that reigned in the central Deccan. It is found originally in that region, but extended to Mysore, where its noblest works were arrested in their construction by the Mohammedan invasion. Its materials are often of volcanic and granitic stone. The pyramidal shape prevails, and the patient elaboration of surface-ornament excites wonder; but in the general outline stiffness and solidity prevail over gracefulness.

The Indo Aryan or Brahmanic style is more widely spread than any of the others, extending as it does throughout the northern and central regions. Its examples are varied; many are too small to be effective or significant, but some, such as the group near Jaganath, in Orissa, and that at Brindaban, on the Jumna, are of the grandest type. Artistically the Orissa examples are perhaps the

best in the whole country. The forms are influenced by Mohammedan example. The rounded and coroneted tower already mentioned in the Jaina style is found to perfection here. In northern India it is called the Shiwala. This style is adapted not merely to temples, but to cenotaphs for the repose of ashes after cremation, to palaces and summer houses, to fortresses, to the dams of artificial lakes, to travellers' rest-houses, to wells, and to the spacious reservoirs that are famous under the name of Baoli. The domes and lesser cupolas become frequent. The balconies and windows are much to be admired. One palatial summer-house at Deeg, in Rajputana, is one of the most beautiful buildings of its kind in the world. The modern Hindu work chiefly belongs to this style, and is still going on. In general terms, observation of nature, aspiration for beauty, and artistic feeling have characterised the Hindus—whether Buddhist or Jain or Brahmanic and imparted to their architectural achievements an art-culture rarely surpassed by any nationality.

The Indo-Saracenic Style.—This may be divided into two parts, the Pathan and the Mogul. It begins with the 11th century, and ends with the 15th. The early Pathan style, whether in stone, as at Ahmedabad, near the west coast, or in brick, as at Gaur, in Bengal, far eastwards, consists, with one notable exception, of the Hindu architecture already described, but adapted for a simple worship, and modified with a certain breadth of conception to which the Hindus never attained. The exception is this, that sculpture of the human form is excluded, as being idolatrous. The later Pathan style was based on northern models. Plainness and grandeur are its characteristics, both in the northern and the central regions. The dome, the arch, the minaret are nobly developed; indeed, the dome at Bijapur, in the Deccan, is the grandest object of its kind in the world, and is equally remarkable for structural skill.

The Mogul style began with Akbar the Great in the 14th century. At first it appeared in a somewhat Hinduised form, because the Moslem princes married Hindu princesses. But it soon became purified from a Moslem point of view, and resumed the severe simplicity and grandeur of the later Pathan style, superadding thereto a grace and dignity never surpassed in human art. At first the materials were red sandstone and marble intermixed. But by degrees marble was used more and more, till the culminating example of this style, the Taj Mahal at Agra, was encased entirely with this material, inlaid with precious and parti-coloured stones (see illustration at Agra). After this the Pearl mosque (marble) at Agra and the palace fortresses at Agra and Delhi, and the Jama mosques at Delhi and Lahore (Punjab) are the most renowned examples.

The Indo-Saracenic style is applied largely to tombs, it being the practice of the sovereign to erect his tomb in his own lifetime. Besides this class and the other classes of structure, it was largely applied to caravanserais and to educational institutions (*Madrasas*). In all its later stage, it was marked by surface decoration in coloured enamel on earthen material, with hues of which the brilliancy and quality cannot be imitated in modern times. After the break-up of the Mogul empire, a debased modification of the style was introduced at Lucknow. High as was the art culture in the architecture of the Hindu predecessors, it was even surpassed by the Moslem successors.

III. GOVERNMENT AND MILITARY DEFENCE.

The Empire. Since Queen Victoria was proclaimed Empress in 1877, India is an empire, includ-

ing the British territories and the native states, or, in other words, the Indian allies, feudatories, and vassals of the said empire from the Tibetan and Tartar watershed of the Himalayas to Cape Comorin. It includes, too, every area within their geographical limits, without any exception, except the comparatively small settlements belonging to France and Portugal. The empire is under one supreme authority in India—viz. the Viceroy and Governor-general in Council. It may thus be divided into two categories—the British territories, comprising about three-fifths of the total area, and four-fifths of the total population; and the native states. It will be convenient to dispose of the latter first.

The Native States.—The relations between these and the British government are regulated by treaties in full detail. These treaties have been published in many volumes, and form a record of the utmost value to the student of modern India. Some states do not ordinarily appear in the official tables, though they form an integral part of the empire and are in communication with British political agents. In their internal affairs they are uncontrolled. These are the important Himalayan state of Nepal, and the lesser states of Sikkim and Bhutan. The native states which appear in the official tables occupy more than a third of the area of the empire, and contain more than one-sixth of its entire population. They are thus grouped in the census table of 1891:

Native States.	Area in English Sq. miles.	Population, 1891.
Hyderabad.....	82,698	11,537,040
Baroda.....	8,226	2,415,396
Mysore.....	27,936	4,943,664
Cashmere.....	80,900	2,543,952
Rajputana.....	150,268	12,016,102
Central India.....	77,808	10,318,812
In Bengal.....	35,834	3,296,379
" North-west Provinces.....	5,109	792,491
" Punjab.....	38,299	4,263,280
" Central Provinces.....	29,435	2,160,511
" Madras.....	9,609	3,709,622
" Bombay.....	69,045	8,059,298
Total Native States.....	595,167	66,047,487

Hyderabad as given above is exclusive of Berar, which, however, though temporarily administered by Britain, is a part of the Nizam's dominions, with 17,718 sq. m. and 2,897,491 population. Further, the Shan dependencies of Upper Burma contain an estimated population of 2,000,000, which is not included in the above total.

The relations of the native princes to British authority differ very widely. Some are practically independent sovereigns, except that the suzerain power does not permit any of them to make war on one another, or to form alliances with foreign states; while some are under tolerably strict control. As a rule they govern their states under the advice of an English resident appointed by the Governor-general. Thus at every considerable native court there is stationed a British agent, political or diplomatic. There are in all about 300 states, allied or feudatory, great and small; they are divided into allied (with 20,000,000 inhabitants), tributary (about fifty, with 12,000,000), and protected (about ninety, with 18,000,000).

Another classification is according to the religion and race of the native dynasty:

I. Mahratta, with a total population of 6,250,000; a revenue of £3,300,000; and native armies of 60,000 men. The chief states are: (1) Gwalior or Sindhia (pop. 3,116,000); (2) Indore or Holkar (pop. 1,000,000); and (3) Baroda (pop. 2,185,000). These are Hindu in faith, but may conveniently be distinguished from the other Hindu states. See MAHRATTAS.

II. Hindu, nearly 100 in number, with a population

of 27,000,000; a revenue of £8,000,000; and native armies of 188,500 men. Of these the chief are: (1) Mysore (q.v.; pop. 5,000,000); (2) the Rajputana states, such as Udaipur or Mewar (pop. 1,200,000), Jey pore (pop. 2,000,000), Jodhpur (pop. 2,000,000), and some 14 smaller states; (3) the Madras states, such as Travancore, Cochin, Pudukota; (4) the Bombay feudatories, over 30 in number; (5) the lesser states of Central India, including Rewa and Bundelkhand; (6) Punjab states, including the protected Sikh states, ten larger and five smaller, Patiala being the largest.

III. Mohammedan, with a pop. of 14,000,000; a revenue of £5,000,000; and armies of 75,000. The greatest are: (1) Hyderabad of the Deccan, or the Nizam's Dominions (q.v.; pop. 10,000,000, of whom three-fourths are Hindus, though the dynasty and military power are Moslem); (2) Bhopal (pop. 800,000, nine-tenths Hindu by faith); (3) Bahawalpur (pop. 500,000); (4) Some nineteen others with a collective pop. of 2,000,000.

IV. Frontier, mainly Himalayan and eastern Bengal.—(1) Cashmere with Jamu (pop. 1,500,000); (2) the Pathan (Afghan) tribes; (3) Manipur (pop. 200,000); (4) Bhutan (pop. 200,000); (5) Nepal (pop. 2,000,000).

The feudatory states (excluding Nepal, and without counting small states with an aggregate of about 1,000,000 inhabitants, which have no armies) have together armed forces amounting to 350,000 men, and 4300 guns. The flower of this army has on recent occasions been placed at the disposal of the British government as paramount, and is virtually a part of the imperial forces.

The sum total of these four categories would bring the population up to 60 millions, and the total revenue to 15 millions sterling annually. These states are loyal to the British crown as paramount and suzerain. Their loyalty was proved during the imperial crisis of 1857-58. In the aggregate they form a preservative and constitutional force in the country. The British government takes a paternal interest in the welfare and good government of these states. Misgovernment is effectually prevented. Colleges and schools under British auspices are established for the education of young native princes.

As descendants are frequently wanting in these old families, it was important that the principle of adoption should be recognised, otherwise the state might on the demise of the native prince without issue lapse to the British government as paramount. All fears on this account were set at rest by a decree in 1858 sanctioning the right of adoption according to Hindu or Mohammedan law.

The British Territories.—These, containing (with Ajmere, Coorg, British Beluchistan, and the Andamans) 964,992 sq. m. and 221,172,952 souls, are broken up into eight main divisions for civil government. They were originally in three divisions, called presidencies, which have become historic—viz. Bengal, Madras, and Bombay. The old presidencies of Madras and Bombay still survive as units of government under governors in council as of yore; but every area that does not specifically belong to them is considered to belong to the Bengal Presidency. The last-named presidency, being much the largest of the three, has been subdivided into several divisions. Of these subdivisions the three principal are Bengal, with Behar and Orissa; the North-western Provinces, with Oudh; the Punjab, with Delhi. Each of these is under a lieutenant-governor. The three remaining subdivisions are the Central Provinces, Assam, and Burma, each under a chief-commissioner; of these the Governor-general in Council is technically the governor, but he delegates the greater part of his powers to the chief-commissioner in each case.

The subjoined table thus shows these main territorial divisions, with their areas and populations :

Presidencies	Provinces	Style of Government	Area in sq. m.	Pop. 1891
BENGAL	Bengal, Behar, and Orissa	Lieutenant-governor.	151,543	71,346,987
	North-western Provinces and Oudh.	" "	107,503	46,105,085
	Punjab and Delhi	" "	110,007	29,886,847
	Central Provinces	Chief-commissioner.	86,501	10,781,294
	ASSAM.	" "	49,004	5,476,833
MADRAS	BIRMA	" "	171,430	7,005,560
BOMBAY	Madras	Governor in Council	141,189	35,630,340
	Bombay with Sind.	" "	125,144	18,901,123
Total.			942,981	217,537,169

Besides these there are three small detached territories—viz. Ajmere (in Rajputana), Coorg, and the Andaman Islands. All this is exclusive of the Berar province, which, though under British administration, is a part of the Nizam's dominions.

These figures, large as they are, fail to give a definite impression of the enormous area and population under British authority in this part of the globe. The districts under direct British administration have an area almost quite as large as that of the United Kingdom, Austria-Hungary, Germany, France, and Italy together, or more than seven times that of the United Kingdom. The area of the native states is as large as Norway and Sweden, Spain, Holland, and Belgium put together. In population British and feudatory India together have more than all European states together, omitting Russia only. The British territories (without the native states) contain more than one-seventh of the inhabitants of the entire globe.

Machinery for governing.—In 1858 the government was transferred from the East India Company (q.v.) to the crown. In 1877 the Queen assumed the title of Empress of India (Kaisar-i-Hind). The government of India is in the highest resort vested in a Secretary of State in London, who is a member of the cabinet, and has a parliamentary under-secretary and a council of ten to fifteen members. The executive government in India is administered by the Viceroy and Governor-general in Council, acting under the control of the Secretary of State for India. The Viceroy and Governor-general, appointed by the crown, is assisted by an executive council, consisting of six ordinary members (appointed by the crown), each of whom has charge of a department of the executive; together with one extra-ordinary member, the commander-in-chief of the army. This council virtually sits as a cabinet. The legislation for the empire is conducted by a 'legislative council,' composed of the members of the executive above mentioned, together with members from six to twelve in number appointed by the Viceroy and Governor-general. Such is the mechanism of the government of India.

In the several subdivisions of the Bengal Presidency the lieutenant-governors and the chief-commissioners above described, in their executive capacities, rule individually. But two of them, the lieutenant-governors of Bengal and of the North-western Provinces, have legislative councils for provincial legislation. The lieutenant-governors and the chief-commissioners are mainly chosen from the civil service of India. The members of the legislative councils are all appointed, the elective principle not having been as yet introduced. Madras and Bombay are under governors appointed by the crown. Each of them has an executive council, sitting as a cabinet, also appointed by the crown, and a legislative council. With the governor-general, the governors, the lieutenant-governors, and the members of council, the tenure of office is for a term of five years. There are proposals for enlarging the several legislative councils.

The country is divided into territories technically designated 'regulation' and 'non-regulation.' In

the non-regulation territory originally more discretion was allowed to the officials both in the collection of revenue and in the administration of justice. But of late the distinction practically amounts to little more than form, and is technical chiefly. In the regulation districts the judicial service is distinct; in some of the non-regulation it is not. The lieutenant-governorship of the Punjab and the several chief-commissionerships are non-regulation; so are some few outlying tracts elsewhere. The rest of the country is regulation.

The Units of Administration.—The larger units are the districts (generally called collectorships in English and *zillahs* in the vernacular), of which there are in all the provinces above mentioned about 254. Each district, if in regulation territory, is under a collector-magistrate; if in non-regulation territory, a deputy-commissioner. The head of the district has most multifarious and responsible duties: he is fiscal officer, charged with collecting the revenue, as well as magistrate, and besides superintends police, gaols, education, sanitation, and roads. In parts of the non-regulation territory he is also the civil judge, but not in regulation territory. The subordinate officers are deputy-collectors and assistant-magistrates. The district may be compared to an English county or a French department, and varies in size from an area containing 3,000,000 inhabitants to one with only 50,000. Within the district the lowest unit is the village or parish (*mouzah*), according to the village system already described. There are about 570,000 such villages or parishes in the British territories. In all the divisions of the empire, except Madras, the districts are formed into groups, several to each group, under a commissioner. Of these there are more than fifty.

The State Services.—The administration is conducted by members of the Indian civil service (formerly called the covenanted), the great majority of whom are European, though some are natives. The service is recruited from the successful candidates at competitive examinations held in London; but some natives have been allowed to enter the service by nomination, and these are called statutory. To this service most of the higher administrative appointments are secured by act of parliament. The local civil service (formerly called uncovenanted), appointments to which are mostly made by the authorities in India, is composed of Europeans, Eurasians (the offspring of native mothers by European fathers), and natives. Some of the Europeans are appointed in England, especially those who belong to scientific departments. The organisation of the native branches of the civil service, with pay, promotion, and pension, is a feature in British rule, and, together with the state education, is beneficially affecting the national character. Thus, while the direction is in European hands, the great mass of civil officials consists of natives.

The European Community.—Existing mainly at Calcutta, Madras, and Bombay, this body consists of the merchants, manufacturers, barristers, lawyers, and other professional men. This non-official body, together with the official body,

constitutes a force of independent opinion, which is a factor in the progress of the country. It is supported by an English press. The newspapers are published not only at the presidency cities, but also at all the provincial capitals.

The Army.—In 1859 the troops of the East India Company became the Indian military forces of the British crown. The established strength stands at 218,729 officers and men. Of this total 145,177 belong to the native army, and 73,552 are European troops of the regular British army. In the total of the native troops a limited number of European officers is included. The forces were divided into three armies, named after the 'presidencies' of Bombay, Madras, and Bengal. But in 1895 these commands were abolished, and the control of the governors of Bombay and Madras ceased; there are now four commands—Punjab, Bengal, Bombay, and Madras—each under a lieutenant-general, who is under the direct command of the commander-in-chief in India and under the control of the government. Out of 103 batteries of artillery 88 are manned by European gunners. The power and mobility of the army have been vastly augmented by the railway system hereafter to be mentioned, especially in the direction of the fortified military posts on the north-west frontier. The old forts, which are also arsenals and magazines, are maintained at Madras, Bombay, Allahabad, Delhi, Agra, Lahore, and elsewhere. Fort William at Calcutta was scientifically constructed early in the century. The barracks for the European troops have been reconstructed on modern principles, and are among the best structures of their kind to be found in any country. The native troops are recruited by voluntary enlistment, with good prospects of pay and pension, from all nationalities and from all castes, Brahmans or others. Though the regiments are commanded by European officers, there are native commissioned as well as non-commissioned officers. Both classes are usually drawn from the ranks. The drill and discipline are European. Volunteering is largely in vogue among the European communities in the capital cities, on the principal lines of railway, and elsewhere. Several battalions have been formed, which constitute an effective addition of more than 18,000 men to the military strength of the country.

The Maritime Force.—This was for many years furnished by the Indian navy under the East India Company. This was abolished after a long and honourable career, in 1863, and the command of Indian waters was undertaken by the royal navy. Fifteen vessels or more are stationed in these waters, with headquarters at Bombay, under an admiral commander-in-chief; the Indian treasury contributing a yearly sum towards the cost of this arrangement. There is also a marine department at Calcutta, and at Bombay for military transport. Two ironclads for harbour defence are kept in Bombay harbour, which for spaciousness and defensibility ranks in the first class of harbours in the world. Madras has merely an open roadstead. But Calcutta has to be approached by eighty miles of river-navigation, which can be conducted only by pilots of life-long training; and it is therefore absolutely defended by nature. Rangoon, near the mouth of the Irawadi, has a similar advantage, but in a lesser degree. Kurrachee, near the mouth of the Indus, though good, is not large enough for the importance of its situation. To these should be added Aden, which, though a plutonic promontory of Arabia, commanding the entrance to the Red Sea, is yet a part of the Indian system—a first-rate fortification and an imperial coaling station (see COALING STATIONS).

Two great steam-navigation companies, with headquarters in London, but plying in eastern

waters, form an addition to the maritime resources of the country for war or other emergency. Their ships, though officered of course by Europeans, are manned chiefly by Mohammedans from the coast-districts (Lascars), who are excellent sailors.

IV. CIVIL ADMINISTRATION.

Law and Justice.—The fundamental institutions of the Indian empire have been established by parliament in a series of statutes. The regulations of the East India Company provided for civil procedure, leaving the native laws to be observed in social affairs, and British justice to be followed in other affairs. The supreme courts established by the crown in the presidency towns of Calcutta, Madras, and Bombay, towards the end of the 18th century, administered the English law. In 1833 the English government set up a commission to frame a body of substantive law, civil and criminal, for the British-Indian territories. This commission and its successors laboured up to a recent time; and with their help a penal code, a civil procedure code, and several other fundamental laws have been passed. The legislative work, both civil and criminal, is highly scientific as well as practical, and is framed after the best models to be found anywhere. In 1853 a legislative council in India was set up. In addition to this several local legislatures were established in 1861, and these may hereafter be enlarged. About the same time the supreme courts were abolished, and in their stead High Courts were established to control the whole administration of justice inside and outside the presidency towns. Great care has within the last generation been taken with the organisation of the native judicial service under the supervision of the European civil service. Courts of various grades (over 2000 altogether) exist in all parts of the districts already described, so as to be accessible to the people. In such a society as that of India there must needs be defects and shortcomings in the judicial system, but on the whole it commands popular confidence, as is proved by the extent to which it is brought into use. In 1880-89 the number of civil suits in the whole country has risen from 1½ to 2 millions annually, and the value from 14 to 20 millions of tens of rupees. Of these about two-thirds are for small sums of less than £10. In the criminal department about 1¼ million of crimes and offences are reported annually; for these cases about 1¼ million persons are brought to trial, of whom over half are convicted. The suppression of gang-robbery and other crimes of overt violence forms a marked feature of British administration—besides the extinction of the criminal practices mentioned under the head of *Social Customs*. See the *Anglo-Indian Codes*, ed. by Whitley Stokes (vol. i. 1887).

Police and Prisons.—The regular police include a force of 160,000 officers and men; the cost of 15,000 is defrayed by municipalities, and of the remainder by the state. Further, there are besides the village watchmen, about 560,000, corresponding to the number of villages. The constabulary is a native force, the principal officers only being Europeans. It is subject in all respects, except internal discipline, to the magistracy, and in each province is under an inspector-general in each division of the empire. There is one regular constable to 7 sq. m. and 1300 inhabitants—which indicates the peaceful habits of the people. Great care has been taken in the scientific construction and supervision of a prison in almost every district. There are upwards of 230 prisons, with about 82,000 prisoners, inclusive of 12,000 transported to a convict settlement at the Andaman Islands.

Education.—The existing system may be dated from 1854, though various efforts had been made

long before that date. Compulsory attendance has not yet been enacted. Still the attendance at school is considerable, though nothing like what it may yet become. There are three principal universities, at Calcutta, Madras, and Bombay, each having many affiliated colleges; there are also two new universities in the North-western Provinces and the Punjab. These institutions are successful, save in one respect—that very many enter them who do not take degrees; about 14,000 pass the entrance examination annually, of whom less than 3000 take degrees. The educational institutions are of several kinds, public, aided, private and unaided; all together they amount to 134,000 in number, with 3½ millions of scholars. These numbers, though actually large, are not so relatively to the population. Of these students not more than one-twelfth consists of girls. The income comes from various sources, government grants, and provincial revenues, local rates and cesses, municipal funds, and fees paid by the parents; the total amounts to 4½ millions of tens of rupees annually, and the expenditure is, of course, commensurate. The English language, with all the western literature, arts, and sciences, is taught to the upper students everywhere. Much, however, remains to be desired in respect to physical science, and technical instruction is still in its infancy; the native mind seems as yet to lean towards literature rather than the exact sciences, towards the cultivation of the memory and the imagination rather than of the reasoning faculties. But intellectual assiduity is evinced in a commendable degree. There are numerous missionary colleges. Schools of art have been organised in the capital cities; there is an imperial museum at Calcutta, and museums in all the chief cities and towns. The native languages, both classical and vernacular, are also cultivated sedulously. A vernacular literature of primers and elementary works, also of more advanced works, chiefly translations, is springing up under the auspices of the British authorities, vast numbers of such works appearing annually. In the whole country there are about 400 newspapers in the various vernacular languages. Their total circulation is not very great, the largest circulation of any journal being 20,000 copies. They enjoy virtually a complete freedom.

Post-office and Telegraphs.—There are 22,000 post-offices and letter-boxes in the Indian empire, with 41,000 men employed. The number of letters, newspapers, parcels, and packets is in all 375 millions annually. This number is fast increasing; though large actually, it is not very considerable in relation to the population. There are open 32,000 miles of inland telegraph lines, with nearly 3 millions of messages annually. This number is exclusive of the submarine cables.

Trade.—The following figures are taken from the Indian returns, which, owing to differences in valuation and exchange, do not agree exactly with the English returns. The imports in 1894-95 by sea were valued in tens of rupees at 79 millions merchandise (including government stores), 9 millions treasure, total 79; the exports at 109 millions merchandise, and 8 millions treasure, total 116. (In 1894-95 the rupee was approximately equal to 1s. 3d.) Thus the grand total of imports and exports stood at 196 millions. Of the imports more than four-fifths, and of the exports more than half, pass by the Suez Canal. Again, of the imports nearly all come from the United Kingdom; but of the exports, while more than one-half goes to the United Kingdom, a considerable portion is sent to other countries. Of the imports the principal item consists of cotton goods; the next most important is that of metals; other important items are machinery, railway plant and rolling-

stock, manufactured silk, sugar, and woollen manufactures. Among the exports there is no preponderating article like cotton goods among the imports; but the principal items of export are coffee, raw cotton, cotton twist, yarn, manufactures, dyes, grains, including rice and wheat, hides and skins, jute, raw and manufactured, seeds (oil chiefly), tea, wool. The growing exportation of food-grains in vast quantities has disturbed or dissipated any notion to the effect that the increasing population might be in want of sufficient sustenance. Of shipping, 10,893 vessels, with a tonnage of 7,189,465 tons, entered and cleared the ports; of these almost the whole were British, a small fraction only being foreign. All this is exclusive of coasting trade, valued at 80 millions annually, with smaller craft along a coast-line of 7000 miles and more, with 300 harbours, mostly small. There are influential chambers of commerce at the principal seaport towns, mixed bodies of Europeans and natives.

Communications.—The length of railways open for traffic may be stated thus (for 1895): guaranteed companies, 2590 miles; assisted companies, 407; state lines, 14,145; native states, 838—total, nearly 19,000. The total number of passengers on all these lines in 1894 was upwards of 146 millions; the quantity of goods conveyed upwards of 32 millions of tons. The gross receipts of all these lines were well over 25 millions (tens of rupees). The net earnings, after defrayal of working expenses, were 13 millions.

Road-making was being vigorously prosecuted, but became somewhat superseded by the introduction of railways. Several magnificent trunk lines have been constructed. Of the total length in the whole country (60,000 miles) about one-third has been bridged and macadamised. Similarly the railways compete with the old boat traffic on the great rivers. This traffic, however, still exists to a wonderful extent in eastern Bengal, where the boats of varied size and build form a conspicuous feature in the country.

Manufactures.—These, whether in metals or in fibres, have always been very fine, and are still maintained. The local manufactures of cotton goods are very extensive. The beautiful fabrics of all sorts are mostly kept up. The foreign trade, however, has during the 19th century checked the development of indigenous manufactures. On the other hand it has stimulated new manufactures, especially in jute and cotton. The cotton-mills at Bombay, organised on the British model, with British capital and direction, but with native labour, have been considerably developed, and threaten to enter into competition for the Indian market. A factory law, on the English principle, but not exactly with English provisions, was passed in 1881.

Irrigation and Canals.—This subject has owing to climatic exigencies attained vast dimensions. Native dynasties have all distinguished themselves in this direction; drought and famine have always urged every government to action, and the work has been taken up by the British government with its western skill and capital. The Ganges canal with its branches, the canal systems of the deltas of the Mahanadi, the Godavari, the Kistna, and the Kaveri, are among the greatest works of their kind in the world. Great canals are drawn from the five rivers of the Punjab, and the Indus is to Sind what the Nile is to Egypt. These irrigation canals are but little used for navigation. The total length of these and their branches is calculated at 14,000 miles. Besides the canals there are in many districts artificial lakes; wells also for irrigation are found in most of the valleys everywhere. The irrigated area in its grand total is reckoned at 28

millions of acres, of which over 8 millions are watered from canals. The capital outlay on this enormous system cannot be estimated, but the British government has in this way laid out 31 millions of tens of rupees, besides sums spent yearly out of current revenue. The embankments along the Lower Indus and in the Gangetic delta for restraining floods are very extensive, having a total length of about 1500 miles.

Famine Relief.—All this bears on the prevention of famine by state aid. Owing to extensive failures of the monsoon rains at periodically recurring intervals, droughts and famines have occurred. Though the natives bore up against their misfortune with admirable fortitude, and brought out reserves of food such as few nationalities could produce, and though the authorities put forth strenuous efforts, yet the loss of life has been sometimes tremendous. In 1874 the principle was followed of devoting the entire resources and power of the government to the mitigation of distress or the saving of life. In years of plenty a sum varying from 1 to 1½ million sterling is set aside out of current income to meet the cost of relieving distress in time of famine. During the period 1874-80, £16,000,000 was thus expended; in 1896-98 alone, over £4,000,000.

Municipalities.—Municipal corporations (at Calcutta and Bombay elected by the ratepayers) have been established in all the cities and large towns of the empire, their total number being nearly a thousand. The population under their jurisdiction amounts to 14 millions of souls; their annual income to 2½ millions of tens of rupees; and their debt to nearly 5 millions.—In many districts the establishment of district boards, by popular election, for purposes resembling those of county government in England, has been undertaken since 1880.

Vital Statistics and Sanitation.—This subject has for many years past received systematic attention. The water-works at Calcutta, Bombay, and other places rank high among works of this character in any country of the world; and the purification of the drinking-water in many centres of population has beneficially affected the public health. The instruction of the natives as qualified medical men and as medical assistants has for many years been supported by the government. Medical colleges at the capital cities, and medical schools at other places, have been established successfully. There are more than 1500 dispensaries for gratuitous medical relief, which receive about 250,000 persons indoors annually, besides relieving 10½ millions of outdoor patients. There are more than twenty lunatic asylums, with some 3500 inmates. Several millions are vaccinated annually. Sanitation is everywhere a department of state administration; and every province of the empire has a sanitary commissioner. Vital statistics have been collected and compiled. The death-rate for the empire has of late years ranged from 24 to 28·35 per thousand. Of this about 2 per cent. is attributed to cholera, 18 to fever, 1 to smallpox.

Emigration.—Owing to the excessive density of population in several parts of the empire, government has for many years past encouraged and facilitated emigration to the tropical and subtropical colonies, the annual emigration of coolies in 1890-95 varying from 13,000 to 20,000. In 1880-89 the emigration to the Mauritius amounted to 7538 souls; Natal, 8057; British Guiana, 30,142; British West Indies, 39,304; Fiji, 6802; French West Indies, 8712; Surinam (Dutch), 6453—total, 107,008. There is also a considerable migration from the plains and low hills of the central regions to the rice-plains of Burma, and also to the tea-plantations in Assam and in the Eastern Himalayas.

Finance.—The currency is in silver rupees, which alone are legal tender; the subordinate parts of the rupee being sixteen annas, and those of the anna being twelve pai (pies) in copper. The monetisation of silver as sole legal tender to an unlimited amount dates from 1835. There is also a government paper currency, legal tender, amounting to about 16 millions sterling in value. The rupee is nominally equal in value to two shillings; and in former days ten rupees were held equal to a pound sterling. While for Indian purposes the finances were generally exhibited in rupees, of which the higher numbers were a lakh or 100,000, and a crore or 100 lakhs, yet for English purposes they were always exhibited in sterling money; thus, a lakh was reckoned as equal to £10,000, and a crore as equal to a million pounds, and for many years the Indian accounts were exhibited in England in sterling by the process of dividing the rupee totals by ten. In the then relative values of gold and silver this plan answered well, for generally ten rupees were really equivalent to one pound or thereabouts. But during recent years, owing to the depreciation of the rupee, which has fallen at times to below one shilling and fivepence in the exchange, this plan is no longer possible. So now the Indian accounts for England are shown in tens of rupees (or R.x.) whereby the comparison between the figures of recent and of former years is maintained. The finance, then, is shown thus in tens of rupees, for gross revenue and expenditure, excluding capital expenditure on public works. The expenditure is incurred chiefly in India, but partly also in England for India.

Year.	Gross Revenue. R.x.	Expenditure. R.x.
1886-87	77,307,134	77,158,707
1887-88	78,759,744	80,788,376
1888-89	81,006,678	81,659,660
1889-90	81,636,300	82,826,960
1890-94.	90,565,214	92,112,212

There are alternations of surplus and deficit; and after putting one against the other, there had been a surplus during the decade 1881-90. The expenditure has been greatly increased of late years by the depreciation of the rupee. The payments annually to England amount to about 16 millions sterling—for interest on debt, pensionary allowances, and other charges. This sum adjusted in gold has to be paid by the Indian government, which has no money save silver; and in the low state of the exchange these payments become excessive and embarrassing. In order to discharge an obligation of 16 millions sterling India has to remit 23 millions of tens of rupees; thus it is estimated that, as compared with former years, the depreciation of silver has imposed on her a burden of some 7 millions annually (in tens of rupees). The main heads of taxation may be set down in tens of rupees, thus: land, about 23½ millions; opium, 8½; salt, 8½; stamps, 4; excise, 4½; customs, 1½; assessed taxes, 1½; provincial rates, 3½. The grand total of receipts and expenditure has of late years been swollen by the inclusion of the receipts and charges pertaining to the railways.

Excluding the opium, which is really paid by the Chinese (see the paragraph on opium revenue below), the taxation above summarised amounts to nearly 47 millions, and falls at the rate of four shillings per head per annum, which is light. Of the expenditure above set forth, there are 23 millions for the army services, which is about equal to the charges for the civil services of all sorts, exclusive of interest. Besides all this, there is a capital account of outlay from borrowed money on productive works, railways, and canals of irrigation. From 3 to 5 millions annually are thus

laid out by the state, besides a nearly equal sum by guaranteed or assisted railway companies.

Public Debt.—The debt thus incurred stands at 93 millions for railways and 27 for canals; in all 120. Besides this there are nearly 120 millions for other purposes, mainly war. The sum of the two amounts to about 240 millions. Of this sum nearly 120 millions (in tens of rupees) are in India and the rest in sterling are in England. There are also obligations styled 'unfunded debt,' consisting of treasury notes, savings-bank deposits, and other items, amounting to 9½ millions. Further, there were more than 90 millions of capital outlay by railway companies, on which the interest was guaranteed by the government. But this has been modified by the fact of government having recently purchased some of these guaranteed lines. The interest charges annually may be shown thus: on railways, state, 3½ millions tens of rupees; guaranteed, 3¼; irrigation canals, 1; other heads, 5½. The rates of interest have been reduced in recent times, and now range from 3 to 4½ per cent.

Banks.—There is a state or presidency bank with various branches at Calcutta, at Madras, and at Bombay, or three in all. The system of small savings-banks has been greatly extended by the government; there are 6151 such institutions, and 331,711 depositors, with a balance of 6,577,737 tens of rupees. The native bankers, between 200,000 and 300,000 in number, form a numerous community that ramifies all over the country, with a well-established system of bills of exchange (*Hundi*). A plan of life insurance by government has been established for the natives, the effect of which may be considerable hereafter.

Land-tenure and Land-system.—This claims notice on social and economic grounds as well as fiscal. The tax is collected in money instead of in kind, as was often the case under native rule. It consists of a portion taken by the state from the agricultural rent—and much the smaller portion. Apart from this, the incidence of tax on the value of the gross produce is reckoned to range from 4 to 10 per cent. in the several provinces of the empire. In all these provinces, except Bengal and Behar, for the assessment of the tax a survey of every field, besides a general survey of every village, has been made. In every village there is a register showing the ownership, occupancy, rights, and interests in every field. This is revised yearly, and called the Record of Rights. This cadastral survey and this Domesday Book for so vast a country, executed by the British government, together constitute the largest operation of the kind ever undertaken in any age or country. Thus the government has either conferred *de novo* on the people, or recognised as belonging to them from antiquity, something which is equivalent to property in land, whether such property existed under previous native rule or not, which is sometimes doubtful. This property is attended by transactions of sale, mortgage, trust, loan, security. The land-tax is the first charge on it; but it is rendered valuable by the moderation in the assessment of the tax.

As regards the land system, there are several tenures, varied by the conditions under which the tax is fixed. The first is that of *fee-simple* after redemption of the tax, under which government lands are sold to European planters of tea or coffee, and others. The next is that where the tax has been fixed for ever, in Bengal, Behar, Benares, and part of Madras, and is styled *Zemindari*. The tenure in Orissa, Oudh, Sind, and the Central Provinces is similar, save that there the tax is fixed for twenty or thirty years. Next is the peasant proprietary tenure of the North-western Provinces and the Punjab, where the tax is fixed for thirty years, and the

proprietors are grouped together in their villages as communities or coparcenaries; this is styled *Mouzalwari*. Resembling this in all respects except one is the *Ryotwari* tenure of Madras and Bombay—the exception being this, that the *Ryot* or peasant-proprietor is assessed individually for each field he holds. Similar to this is the tenure in Assam and in Burma. The village organisation is almost everywhere preserved.

Below the land-owners, great and small, are the cultivators. They are divided into two categories, the occupancy tenants and the tenants at will. The former inherits his tenure, but as a rule cannot sell it without the owner's consent. He is protected by law against exaction and from interference or eviction, so long as he pays the customary or stipulated rent; and generally his rent cannot be increased against his will without a decision of a court of law.

Opium Revenue.—This is for the most part levied on the exportation of the drug to China; the very small portion consumed in India is taxed under the head of excise. The tax on the exported drug from Calcutta amounts to 6½ millions. The cultivators of the poppy are in British territory; they bring their produce to the government factory, and thence it is sent to the seaport, where it is taken up by the exporters. These arrangements are made to secure the revenue and to prevent illicit consumption. The tax on exportation from Bombay amounts to 2½ millions. The produce is raised in the native states of Malwa and Rajputana.

The *salt-tax* is derived from salt partly obtained on the sea-coast of Madras and Bombay, partly from the salt lake in Rajputana, partly from the rock-salt in the Punjab, and partly imported from England. It is the only tax universally paid by the poor, and falls at the rate of sixpence per head per annum on the population.

Excise.—The farming system which used to prevail in the excise on dings and spirits, for the manufacture of which the materials are to hand everywhere in superabundance, has been condemned as likely to lead to the encouragement of drinking with a population that is generally temperate. This is being superseded by a better system, known as that of central distilleries.

Wages and Prices.—As general facts, both wages and prices have risen under British rule. The labourer of the better class will earn four annas (sixpence) a day, the humbler not more than two annas. The price of food-grain may be roughly taken at one penny for 2 lb. (seer), which supplies a fair sustenance. In a family the women and children earn some wages. Clothing is scanty and cheap; fuel but little needed, and can be got without payment. Rent for cottages is but little known. The masses of the rural population, however, are not labourers, but live on their lands either as owners or occupants. Incomes from land are not assessed to income tax, which at a rate of 2½ per cent. yields 1½ million, and thus represents a taxable commercial and professional income of 60 millions—greatly less than that of England with a population only one-fifth as large. Lastly, there is not, and never has been, anything like a poor-law; nor is there any apparent need for one.

V. THE HISTORY.

Phases of Civilisation.—With a country of 1½ million of sq. m., containing a population of 270 millions, of many languages and nationalities, with traces reaching backwards more than three thousand years, an historical summary would become an Indian jangle of names and dates unless it were arranged on a plan and guided by some leading ideas. Without such a method no lesson from the facts would be conveyed. Now, in these days a

strange and complex civilisation is perceived in the Indian empire, and the student should inquire by what steps through the ages this has been brought about. At the basis of this immense social fabric is the prehistoric status of aboriginal races. Of these races many an indication is still perceptible, and of them some are still surviving. This status was largely affected by inroads, Dravidian and other, from central Asia, many centuries before the Christian era. From one of these invasions, which was Aryan, sprang the early Hindu or Vedic system. Whether any previous invasions had introduced civilisation or not, this Vedic system certainly was a civilised one. This became overlaid with corruptions, and was reformed by the Buddhistic system some five or six centuries B.C. Then came the Greek invasion under Alexander the Great and some of his successors, which affected only the north-western parts of the country. It was followed by other invasions from central Asia, some styled Bactrian, others Saka or Scythian, which extended much further than the north-western regions. Meanwhile Buddhism had strengthened and extended itself till it obtained the sovereignty over the whole country. Thus established as a state religion, it lasted for some centuries after the Christian era. Then it gave way to the old Hindu system, revived under an elaborated form which should be styled Brahmanism, and which represents the modern Hinduism. Brahmanism after its re-establishment in the 6th century flourished till the 11th century A.D., when the first Mohammedan invasion took place. This was followed by successive invasions, till the greater part of the country was subdued and parcelled out into various Mohammedan kingdoms. Many of these kingdoms were subdued by one Mohammedan dynasty known as the Mogul. Thus the Mogul empire was established, embracing most parts of the country, in the 15th century. It lasted for less than two centuries, and then began to shrink. Its fall was precipitated by the rise of the Mahrattas, who brought about a revival of Hindu power on the ruins of the Mogul dominion in the 17th century. Meanwhile European influence was beginning to be felt—Portuguese, Dutch, French—all round the coasts, but not far in the interior. This gave way to the British influence, which was established in the middle of the 18th century, and by the middle of the 19th had spread over the length and breadth of the land, being soon afterwards formally proclaimed as the Indian empire. Thus in the India of to-day are to be found traces of (a) an aboriginal condition with some Dravidian civilisation, (b) a civilisation early Hindu or Vedic, (c) Buddhist, (d) Greek, (e) Bactro-Scythian, (f) later Buddhist, (g) Brahmanic or modern Hindu, (h) Mohammedan, (i) Mahratta, (j) continental European, and (k) British. The following summary will briefly indicate the course of events as concerning the several stages in the national life and the development of the mixed civilisation which is seen to-day.

The Aboriginal.—This is prehistoric, and is both without written record and also without coins or inscriptions; but there are philological traces and rude monuments. Roughly, it may be said that there were at least several aboriginal races, and that incursions of tribes from without took place—not, like subsequent invasions, from the north-west, but from various quarters by sea and land. Rude stone monuments are found, and sepulchral remains with primitive implements have been excavated in several parts of the country widely distant from each other. These are of the highest antiquarian interest. They hardly indicate civilisation, but they prove at least a social organ-

isation of a semi-barbaric character. The population was sparse; the face of the country was a primeval forest, dotted about with cultivation and habitations. The stature of the people was small, the skin dark, and the features of a Tartar cast, with broad cheek-bones, low forehead, nose small, mouth somewhat large. Upon this people, whatever it may have been, two inroads were made, one by a race known as the Kolarian, now represented by the Sonthals, the Bhils, and other tribes; the other, from the north-west, called the Dravidian. The origin of the Dravidians is still doubtful. They must have had some civilisation which spread over the whole country, and which, though absorbed by some subsequent systems in the north, is still traceable in the south. Their race in its ruder form is still represented by hill-tribes, Gonds, Khonds, and others.

The Early Hindu or Vedic.—At least a thousand years B.C.—probably much more, perhaps fifteen hundred—an Aryan race from central Asia descended across the Western Himalayas into northern India through the north-west corner, and gradually spread over the whole country. They were, ethnologically, of the Caucasian or Indo-Germanic type, with fair complexion, straight profile, lofty brow, compressed mouth, tall stature. But their complexion was darkened by sojourn below the Himalayas; their hardihood was softened, while their intellect was refined by the hot climate. They received the name Hindu from Hind, that quarter which they first overran. Their language, the Sanskrit, is one of the most highly elaborated forms of human speech. They brought with them the Vedic religion. They produced the sacred verse of the Vedas and the legends on which the two great epics, the Mahabharata and the Ramayana, were founded in a subsequent century. They formed the rules of social ethics afterwards embodied in a code known as that of Manu, or the moral laws of the Manava priests. They came originally without any divisions of caste, but afterwards their society became broken up into castes, rigidly separated from each other. The first or priestly caste, styled Brahman, was held to have a divine sanction, and was kept separate without intermixture from generation to generation. The two secular castes were those of the soldier (Kshatri) and the trader (Vaisya), including all civil pursuits. These three originally consisted of those who immigrated, but they must have been largely recruited by those whom they found in the country, especially the Dravidians. Below these was the Sudra or low caste, consisting of aborigines and miscellaneous country-folk. At the bottom of the social scale were the Pariahs, who were outside the pale of caste. The dynastic and territorial arrangements of this era are but slightly known, but there were capital cities on the Ganges near the modern Patna and on the site of Allahabad.

The Buddhist.—As the faith and civilisation above sketched became corrupted and overlaid by mythology, a reformer arose, afterwards known as Buddha, a man of a noble family, in the region near the modern province of Oudh. Though his memory has been shrouded by fable and mysticism, he was a real personality. He lived about 500 B.C. The simplified and purified faith as he left it to his disciples had spread largely but not entirely over India by the year 337 B.C., when the Greeks arrived. Up to this time there are no proper materials for composing history. The Sanskrit language, though preserved as a classic, had ceased to be a spoken language. It had been succeeded by a modified form known as the Pali, which was the chief of the local vernaculars called Prakrit.

By this time Jainism had arisen. It is considered

by many to be cognate with Buddhism: at all events it sprang from the same school of speculative thought. It maintained a separate existence on similar if not the same principles, and spread from the western regions, where it first flourished, to other parts of the country. After Buddhism had been banished from the land, Jainism remained, and still continues an effective faith.

The Greek.—Alexander the Great, having invaded India from the north-west corner, penetrated only as far as the Sutlej, and subdued the basin of the Indus and its tributaries—i.e. exactly the modern provinces of the Punjab and Sind. Beyond this his influence was not felt in the main portion of the country. One of his successors, Seleucus, however, entered into relations with Chandra Gupta, a Hindu king of the eastern region, who had not yielded to Buddhism, and whose name was turned into Sandrocottus by the Greeks. For this epoch there are historic materials from Greek sources.

The Bactro-Scythian.—The Greek invasion was succeeded by several invasions of tribes from central Asia. The Bactrians were orientalised Greeks, planted in Bactria or Bactria by Alexander, together with central Asiatic Aryans; of these the records are scanty. The Sakas or Scythians were also Aryans from central Asia. In the absence of records, it is here that numismatics begin to play an important part. Coins have been discovered indicating lines and lives of kings, and dynasties which would otherwise be unknown. These tribes penetrated as far as the central parts of the country, and held their position for some centuries after the Christian era.

The Later Buddhist.—Meanwhile Buddhism had produced some great rulers. In the direct line from the Chandra Gupta already mentioned, there arose Asoka, himself a convert to Buddhism, and the greatest sovereign that ever propagated that faith. He established something approaching to an empire about 230 B.C., his original kingdom being in the lower valley of the Ganges. His general edicts have been preserved. He held several councils, the last of which settled the rule of faith for observance during subsequent centuries. For this era stone inscriptions come into use. Then followed the Bactrian and Scythian invasions already mentioned; but the invaders embraced Buddhism. Thus in a certain sense the several tribes of Aryan invaders became amalgamated, and for some centuries after Christ Buddhism in faith and in civil government prevailed over India. Meanwhile it had spread to neighbouring regions, Ceylon, Burma, Tibet, China, and even Afghanistan. From the visits of Chinese pilgrims recorded on two occasions, separated by considerable intervals of time, much is learned of the then condition of the country. But while the faith endured in those regions, it yielded to the old Hinduism, which should now be called Brahmanism. Before it fell Buddhism raised many architectural monuments in various provinces, which still attest its greatness and culture. Simplicity and purity of faith were its original characteristics, and were probably maintained throughout its Indian career, however much it may have become overlaid by superstition elsewhere. At its best it was probably better than any of the native systems that have succeeded it.

The Brahmanic or Modern Hindu. The subjugation or suppression of Buddhism may be dated from the time of the Brahmanist king Vikramaditya or Vikramajit, in the 6th century A.D. He overcame the Sakas or Scythians, who it is to be remembered had mostly become Buddhists, expelling some, but amalgamating most of them in his own system. He reigned at Ujjain in the Vindhya region. He antedated, so to speak, his era, placing it back

600 years, or 56 years B.C., and this is the Samvat or modern Hindu era. Thus Brahmanism finally superseded Buddhism. Its doctrines were expounded by the reformer Sankar Acharya in the Deccan, but it soon became crusted over with fables and inventions. The time of Vikramaditya has in western phrase been termed the Renaissance of Hinduism. Certainly it was so as regards Sanskrit literature. This language, long dead for all matters save religion, was revived for the drama and for descriptive poetry. Kalidasa, of this epoch, is among the sweet singers of the olden time. There were searchings and efforts after knowledge in astronomy, medicine, and other sciences. The caste system may have lost its religious efficacy for some centuries, but it retained its secular vitality. The Brahman caste had held its own. The other castes had absorbed most of the immigrants from central Asia. Then for full four centuries the Brahmanic system was re-established all over the country. It was upheld by Hindu states at Avantipur in Cashmere, at Ajodhya in Oudh, on the coast of Orissa, at Kanouj and Benares on the Ganges, at Delhi on the Jumna, at Surat on the west coast, at Vijayanagar in the southern Deccan, and elsewhere. It produced many splendid fables, the mins of which delight the modern observer. It was characterised by a fantastic mythology and a somewhat sensuous idolatry. It produced, in addition to the old eode of Manu, a further set of regulations under the name of Yajnavalkya. Minute ceremonial observance, varying for every class, cramped the soul. Thus the spirit of the people was enslaved, their sentiments were cramped, and their thoughts awe-struck. Their mind was turned to superstitious requirements rather than to the practical questions of public life. Their society was further enfeebled by the subjection of women. Maternal and conjugal influence must have existed, but in an irresolvable way. Each one of the countless sections of the community, each tribe or class, each consinhood descending from a common ancestor, within its narrow circle became tenacious of its own traditions, guarding them against all the world, and caring little for anything extraneous. Hence arose the system of village communities, which was consolidated and hardened by the recurring troubles of the time. Each community was a brotherhood within its village only, with cohesion like that of a square of infantry. This institution saved Hindu society during the convulsions of the 11th and succeeding centuries. But a society thus constituted was manifestly a ready prey for northern invaders. During the later part of this era there were apparently some internal revolutions among the Hindus themselves. Then in 1001 A.D. came the Mohammedan invasion. Up to this date the history of the country remains to be written, in the English language at least; the nearest approach to it is Lassen's *Indische Alterthumskunde* (4 vols. 1844-61; 2d ed. 1866 *et seq.*).

The Mohammedan.—In 1001 Mahmud of Ghazni invaded India through the passes of the Suliman Mountains. From this time onwards the history of India can be fully understood from abundant materials, though the details are intricate. Several Mohammedan dynasties in succession established themselves at Delhi, others at Mandu in the Vindhya, at Ahmedabad on the west coast, at five places in the Deccan, of which the two most famous are Goleonda and Bijapur. At all these points architectural remains bear witness to culture and power. Thus almost all India fell under Mohammedan dominion. About the year 1200 the Mongol Genghis Khan devastated the north-western part of the country. Succeeding Mongol invasions were repelled by the Indian Muhamme-

daus, but in 1397 the Tartar Timur or Tamerlane advanced to Delhi and proclaimed himself emperor of India. This title lapsed for a while, till in 1525 his descendant Baber revived it, and became the first who bore the famous title of the Great Mogul. His descendants subdued one by one most of the Mohammedan states in the upper half of India, and became emperors in reality; but the states in the southern half preserved independence more or less. Baber's grandson, Akbar the Great, made this empire effective with the aid of a Hindu minister, Todur Mol. He was perhaps the greatest sovereign that India has ever seen. His code of regulations, the *Ayin-i-Akberi*, is still studied. His reign and the reigns of his three successors were splendid, and their architectural remains evince an artistic culture hardly surpassed in any age or country. Of these three the last was Aurungzebe, a man of masterful ability, disfigured by a cruel bigotry. In his time the empire began to shake, and a new Hindu power was set up—the Mahrattas. After his death in 1707, the decline and fall of the Mogul empire set in rapidly. In the general cataclysm which followed four fresh Mohammedan kingdoms rose to the surface—viz. that of the Nawab Wazir of Oudh, that of the Nizam of Hyderabad in the Deccan, that of the Nawab of the Carnatic, that of Hyder Ali and Tippoo at Seringapatam in Mysore. All four are much heard of in the 18th century. After the fall of the empire the titular Great Mogul remained at Delhi till 1857. The Mohammedan system inculcated simplicity of faith and morals. It was bitterly opposed to idolatry, and was at first iconoclastic, but in the end it extended toleration to Hinduism. It fairly respected the landed property and endowments of that religion. It introduced some fresh ideas, and imparted some breadth of ideas generally, and some improved notions of statesmanship and organisation. Otherwise it produced but little effect upon Hindu civilisation. It imposed its own official language and its own criminal law; but it maintained civil laws and customs for the most part. It undertook no public instruction save that which was Moslem. It planted Moslems all about the country, but did not convert the indigenous people in large numbers anywhere except in one quarter. That exception was eastern Bengal, where the inhabitants embraced the Moslem faith; but how this came about is a question not settled. It has been conjectured that Buddhism survived here without caste, and that the inhabitants were not unwilling to adopt Mohammedanism, as a casteless faith. Be this as it may, the eastern Bengal population has multiplied till it amounts to nearly 25 millions, and is the largest Mohammedan people now existing in any one country. Finally, the Mohammedan power endured so long as it was recruited from trans-Himalayan regions and the hardy north; it soon lost its strength when its supporters came to dwell from generation to generation in the hot country below the mountains.

The Mahratta.—The rising of the Mahrattas against the Mohammedan domination was begun in 1657 by Sivaji in the Western Ghats. Their dominion advanced as that of the Great Mogul receded. It was a low caste Hindu confederation, with a hereditary Brahmin chief at its head, under the title of Peshwa, at Poona in the Deccan. Though it absorbed the Mogul empire, it never overcame the four fresh Mohammedan states above mentioned; but it was the principal power existing when the Europeans appeared in force on the scene. It governed its native Deccan territories tolerably well; and to the north of them it founded several states which still endure prosperously. Still, it had less civilisation than any

power since the Vedic-Aryan invasion, and it threw many parts of the country into confusion. Under its shadow some fresh evils sprung up, such as Thuggee and the organised bandit system known as Pindariy. During this hapless time occurred irruptions under the Persian Nadir Shah and the Afghan Ahmed Shah; but these invaders came, slew, sacked, devastated—and turned back again without permanently affecting the country. In the overthrow of the Mogul power that ensued, there arose a fresh system in the Punjab—viz. the Sikh. A prophet arose named Baba Nanak, who preached a reformation of Hinduism. He was followed by Govind Singh, who established the system by force of arms in the Punjab, and even as far as the Junna. Thence arose a Sikh dynasty, which lasted till the middle of the 19th century. This essentially Hindu power cut off the Indian Mohammedans from what had been their original base in Afghanistan, and left them isolated amidst their foes.

The Continental European.—In the time of the Moguls and the Mahrattas several European nationalities appeared in India as travellers, traders, missionaries. The Dutch had several settlements, of which the memory still remains. The Portuguese, after the discoveries of Vasco da Gama, controlled virtually the whole west coast, excepting Bombay, then a small place. Their headquarters were at Goa, on the coast south of Bombay, which became a town and a harbour of the first rank in the 18th century. The Portuguese influence affected civilisation in the western region to a perceptible degree. In the 18th century the position of the French rivalled that of the English; the wars between the two nations were carried into the East, and the contest was waged on the waters as well as on the land of India. The name of the great Frenchman Dupleix is respected by the British in India as of the worthiest of foemen. Thus the British had to contend simultaneously with French rivals as well as native enemies on Indian soil.

The British.—This begins to be a dominating influence from the battle of Plassey in 1757, won by Clive over the Mogul, which gave to England the dominion of Bengal and Behar, the most populous provinces in the whole country. The British East India Company had been settled in India since 1653. It had three trading-settlements on or near the coast at Calcutta, Madras, and Bombay. These grew into establishments for fighting and governing, and the territorial elements thus formed soon expanded. The acquisition of Bengal with Behar raised the company's territories into a dominion of magnitude. Thus the company in the later half of the eighteenth century appeared as one of the powers. It really rose on the ruins of the Mahratta dominion. Within sixty years from Plassey, that is by 1818, when Poona, under the last of the Peshwas, fell to the British, the East India Company was the master of India as far as the Indus basin, but not in the Punjab nor in Sind. Within these limits it had acquired the whole basin of the Ganges and the coast districts on both sides of the peninsula. The Great Mogul, now powerless, was under its care at Delhi. It had conquered the Mohammedan state in Mysore and restored a Hindu sovereign there. The two Mohammedan states of Oudh and Hyderabad (Deccan) were its dependent allies, though with all honour. It was maintaining many native states, Hindu and Mahratta, in the same position. Among these must be included (after severe fighting) Nepal, the one Himalayan state which was capable of waging war, and which had contended sturdily with British forces. The Pindarries, who raised a robber organisation almost to the rank of a power, had been subdued. The British dominion

had been founded by Clive, preserved during a world-wide crisis for England by Warren Hastings, extended by Cornwallis, and still further advanced by Wellesley, and almost perfected by the Marquis of Hastings. By 1828 there was a Pax Britannica throughout India after centuries of internal war and revolution. How far the East India Company was the aggressor in any of these transactions may be a controversial question. It was often induced to participate in the contests of the native states among themselves; in self-defence it had to fight the combinations formed against its very existence; and being the victor, it had to deal with the vanquished. Thus by various means the fabric of its dominion rose. It had raised a large native army and some European forces of its own, but these had to be sustained by royal troops from England; consequently on each renewal of its charter the company passed more and more under the control of the British government. The next imperial step was in 1825, when the first Burmese war occurred under Amherst; it ended in some acquisition of territory, which was the beginning of a new dominion across the waters of the Bay of Bengal. There was then a development of peaceful civilisation under Lord William Bentinck till 1835. But in 1838 it was decided to set up a native sovereign in Afghanistan under British protection, as a means of guarding the north-western frontier. This led to the first Afghan war, after which the British evacuated that country. This was the first check in a victorious career of eighty years since Plassey. There remained the basin of the Indus yet unconquered—i.e. Sind and the Punjab; the former was conquered under Ellenborough, the latter under Hardinge and Dalhousie after severe fighting in two wars, in which the Sikhs were the aggressors. Thus the Sikh kingdom so ably founded by Ranjit Singh succumbed. Then at length it was said that not a shot could be fired in anger throughout India without leave of the British government. Under Dalhousie also a second war broke out with the Burmese; the result extended British dominion over the delta of the Irawadi. At this time all the works of peace, moral and material, were prosecuted. Shortly after Dalhousie had handed over his charge to Canning the mutiny in the Bengal native army broke out in 1857.

A crisis arose of which the dimensions can readily be gauged by the reader who has followed the various facts already set forth in this article. After the occurrence of some isolated mutinies in the Bengal native soldiery, generally called sepoys, during the early part of 1857, the native portion of the garrison at Meerut, near Delhi, broke out on 10th May; the European garrison failed to prevent them, and the mutineers marched straightway to Delhi, and were joined by the native troops there and by the city mob. The rebels set up as emperor the titular Great Mogul, who dwelt in the ancestral palace there under British protection, and proclaimed the restoration of the Mogul empire. This event was rapidly followed by the revolt of almost the whole native army of the Bengal Presidency. Their comrades of the Bombay Presidency were but slightly affected, and those of Madras hardly at all. At that time the native forces numbered more than 247,000 men of all arms; of these about 50,000 belonged to Madras, 30,000 to Bombay, and the remainder to Bengal; among the latter, however, were many troops called irregular. A large part of the irregular troops remained staunch; but of the Bengal regular troops only seven battalions continued in service. From 80,000 to 90,000 soldiers, horse and foot, were in revolt, having in many cases murdered their officers, and sometimes the European families also. The mutineers, too, who were cantoned over many stations in

broad provinces, held forts, arsenals, treasuries. They were armed with British weapons, had been organised with British discipline, were in possession of much artillery, of a great number of cavalry horses and other transport, and of vast sums of treasure. In Hindustan, in Oudh, and in parts of Malwa, throughout the summer the British power was insulated at certain points, such as the camp before Delhi, the cantonment at Meerut, the fortresses at Agra and Allahabad, the weak fortifications at Lucknow. Elsewhere the European magistracy with their families had been either killed or hunted away, and the court-houses with their records burnt. The disaster extended over at least an area of 100,000 sq. m., with a population of 40 millions. It occurred, too, at the worst season of the year. If not speedily stamped out the fire must spread over the whole country. The year was a centenary of historic events. It was just one hundred years since Clive founded British dominion at Plassey, and two hundred since Sivaji the Marhatta struck a deadly blow at the Moslem power. Many an enemy thought that the knell of the empire had sounded. And certainly, unless the resources of the British Isles could be brought to bear upon the scene of revolt within a few months, the British authority would be narrowed to its three original seats—namely, the presidency towns resting on the sea-board.

At that time there were 40,000 European troops in the country. Several thousand men on their way from England to China at Lord Elgin's disposal were, with his co-operation, diverted to India. Some 40,000 European soldiers were despatched from England round the Cape of Good Hope by a sea-voyage of 12,000 miles. Meanwhile the disasters at Cawnpore and elsewhere in Hindustan had been partially retrieved by Henry Havelock. At the outset a force, largely consisting of Europeans, marched against Delhi. After a severe siege of four months, the place was recaptured by assault. The communications had been maintained continuously with the Punjab, under John Lawrence, as a base whence reinforcements were derived. Native troops were raised from the loyal Punjab in place of the mutineers of Hindustan. Lucknow, for a long while after the death of Henry Lawrence besieged by rebels, was first relieved and afterwards recaptured by a European force under Colin Campbell. The districts were speedily reoccupied by British authority. Though many influential individuals, some chiefs and princes, and some classes, including the worst part of the mob, had joined the rebellion, or rather the military revolt, still the mass of the people in these districts had remained passive, and readily returned to their allegiance. The principal native princes and their states had set an important example of loyalty. Within six months of the outbreak the imperial danger was surmounted, though troubles lasted here and there, and the embers smouldered for more than a year, especially in the hilly parts of the central regions. The cost of suppressing this rebellion is reckoned at 40 millions sterling. Unlike all the earlier foreign dynasties, the British power had never been naturalised or domesticated in the country, but was then, as ever, recruited constantly from the British Isles. Its officers serving in the country had been born and educated in Europe, and possessed as a reserve against danger all the imperial qualities of their race.

Many causes were assigned for the Indian mutiny. The greased cartridges served out to some of the Bengal troops operated as an immediate provocation. The Brahmins were too numerous in the ranks; they were fanatical, and they had the brains to contrive mischief when discontented. The Kabul disaster had broken the spell of invincibility.

bility. Certain chiefs near the scene of the outbreak were labouring under a sense of wrong, real or supposed. Some native states had been alarmed at British policy with regard to the right of adoption. The annexation of Ondh, however righteous in itself, had induced many Mohammedan conspirators to excite mutiny, and to turn it to political account. This brought about a very unusual combination between Mohammedans and Hindus. Still, these and other lesser causes would never by themselves have brought about such a crisis as that which has been described. The prime, the fundamental cause was a large and simple fact, namely this. The native forces were much too large relatively to the European. There was only one European soldier to six native soldiers, whereas now there is one to two. The sepoys then had the physical force in their hands, and they knew it. The distribution, too, of these excessive numbers aggravated the peril. The sepoys were, as already seen, in charge of the stations containing the state resources, civil as well as military. It was the sense of power which gave them the mind to revolt. Their interests, including employment, pay, pension, and the like, were indeed bound up with the British rule. The government was over-slow to believe that the men would revolt to the destruction of their own prospects. But their conduct proves that there are moments when religious fanaticism, national sentiment, pride, and passion will prevail over self-interest. The occurrence was only a question of time, and many will wonder why it did not happen before. But an analysis of historic circumstances would show that never before had a complete opportunity offered. Mutiny of particular bodies of troops had often occurred already, and had been overcome. Thus the British authorities came to be insufficiently alive to the symptoms which portended the events of 1857. But after the storm had burst they evinced qualities rarely surpassed in the annals of the nation, and the history of the time is aglow with genius, valour, and capacity.

The crisis past, no time was lost in rectifying the military faults which had rendered the revolt possible. The native troops were reduced in number, the European troops were augmented. The physical predominance at all strategic points was placed in the hands of European soldiers, and almost the whole of the artillery was manned by European gunners.

Peace and order having been restored to the empire in 1858, various changes, constitutional and other, were made. The East India Company, the greatest corporation ever known to history, ceased to exist, and the government was assumed by the British crown. The army was reorganised so as to guard against the danger from which the country had just been saved. As compared with the relative proportions of former times, the European force was doubled, while the native force was reduced by more than one-third. Thus, as already seen, the European and the natives were as one to two; moreover, the European was placed in charge of the strategic and dominant position, so that the physical power was now in his hands. The dominion was consolidated by the work of peace under successive viceroys, Elgin, Lawrence, Mayo, Northbrook, with material improvement and moral progress. In 1878, under Lytton, a second Afghan war was waged, which led to the strengthening of the north-western frontier. The work of peace was continued under Ripon till 1881, when, under Dufferin, it became necessary to proceed against the king of Ava, and subsequently to annex Upper Burma. This measure, following previous annexations, brought the whole Burmese dominion and the entire region of the Irawadi

in India in contact with China. The year 1896-98, under Lord Elgin, saw famine, the plague in Bombay, earthquakes in Assam, and a troublesome but successful war on the north-western frontier. British civilisation, by legislation, by peace and order, by education, by works of material improvement, by Western ideas, is moulding the mind of nearly all the nationalities in the empire.

Books of Reference.—There is not space here for attempting a review of Anglo-Indian literature, which is very extensive. Some few works only will now be mentioned, which are of a comparatively popular character and are readily accessible. For history, the best-known works are those by Mill and Thornton, and the shorter one by Marshman. Regarding special periods, Mountstuart Elphinstone, for the Mogul era; Keene, for the decline and fall of the Mogul empire; Grant-Duff, for the Marhattas; Malleson, for the French in India; Kaye, for the first Afghan war; Kaye and Malleson, for the war of the mutinies in 1857-58; Trotter and Maine, for the Victorian era. Much light is derivable from the biographies of Clive, Warren Hastings, Metcalfe, Macaulay, the Lawrences (Henry and John), Mayo, and Dalhousie. There are also recent histories of India from the earliest times by Trotter (1890), Talboys Wheeler (1891), and H. G. Keene (1893); of Ancient India, by Romesh Chunder (3 vols. 1889-91); of the British Dominion in India by Sir A. Lyall (3d ed. 1894); of the Portuguese in India, by Dauvers (1894); a series of 'Epochs of Indian History,' edited by J. Adams; and valuable papers on the Indian Mutiny, selected by G. W. Forrest. See also the *Imperial Gazetteer of India* (2d ed. 11 vols. 1885-87), edited by Sir W. Hunter, and his *Indian Empire* (3d ed. 1893); *Modern India*, by Campbell, *Modern India and the Indians*, by Monier Williams (1889); *India Past and Present*, by Samuelson (1889); *India in 1889*, by the present writer; *Our Indian Protectorate*, by C. L. Tupper (1893); *The Protected Princes of India*, by W. Lee Warner (1894); *The Land Revenue of India*, by Baden-Powell (1893); and *The Conversion of India*, by Dr George Smith (1893); also Curzon's *Russia in Central Asia* (1893), and Dilke's *Problems of Greater Britain* (1890). To these should be added the reports by the government on the moral and material progress of the country, and the volume of statistics published annually by the Indian Office in London. The *Journal of the Royal Asiatic Society* and the *Calcutta Review* supply quite a mine of materials. Some light is thrown on this great subject by Tod's *Rajasthan*, Rajendralal Mitra's *Antiquities of Orissa*, Rhys Davids on Buddhism, Franqui on the Parsees, Talboys Wheeler's *Mahabharata and Ramayana*, abstracted in English; Max Muller's analysis of oriental religions; the translations of the sacred books of the East; Barth's *Religions of India* (Eng. trans. 1882); Monier Williams' *Indian Wisdom*, and his *Brahmanism, Buddhism, and Hinduism* (1889); Lyall's *Asiatic Studies* (2d ed. 1884), Edward Thomas' *Numismatic Essays*, and Fergusson's *History of Indian Architecture*. Indian architecture is illustrated at the articles on AGRA, BENARES, ELEPHANTA, ELLORA, &c. And see amongst others the following articles in this work:

India. STAR OF. See INDIAN ORDERS.

Indiana, the thirty-first state of the American Union in area, and the eighth in population, is centrally situated between 37° 47' or 180 1800 in P. S. and 41° 50' N. lat., and in 84° 49' or 180 1800 in E. B. Lippincott —88° 2' W. long. It is bounded or 180 1800 on the N. by Lake Michigan and Michigan state, on the E. by Ohio, on the S. by Kentucky, from which it is separated by the Ohio River, and on the W. by Illinois, the Wabash River being the line

of division a part of the way. Its greatest length north and south is 276 miles, its average breadth 140 miles, and its area 36,350 sq. m. The coastline on Lake Michigan is about 60 miles.

The surface of the country has a slight slope towards the west and south-west, the highest point, near the eastern boundary, being 1250 feet above sea-level. Drainage is in four main directions: through the St. Joseph River to Lake Michigan, the Maumee River to Lake Erie, the Kankakee River to the Mississippi, and the Wabash and other streams to the Ohio; small streams intersect the state in every direction, and in the northern part there are numerous small lakes. The northern half of the state is generally level, except for occasional irregular ridges forming 'divides' between streams. Hills increase in frequency from the centre of the state to the south and south-east, and along the Ohio 'knobs' 200-500 feet high are almost continuous, with deep gorges and river-bottoms between. Much of the north-western regions is inundated with water the greater part of every year; but this land is being actively reclaimed by a system of drainage. The fertility of the soil, whether clay or sandy loam, is greatly increased by a vast system of under-draining, there being in 1888 nearly 25,000,000 yards of drain-tiles in use.

The minerals include coal, bog and hematite iron ores, and stratified limestones and sandstones in abundance, ochre beds, kaolin, fireclays, and some gold. The actual workable coalfield covers an area of 6900 sq. m. The production of coal of all kinds amounted in 1870 to 437,870 tons, in 1880 to 1,449,496 tons, and in 1888 to 3,140,979 tons, mostly block coal, although there is also abundance of bituminous and some cannel coal. The natural gas field, the centre of which is in Delaware county, 40 miles N.E. of Indianapolis, has been developed since 1886, and \$6,000,000 was invested in 1888 in the business of supplying it for fuel, there being 395 wells in twenty-three counties. In 1897 there were 2000 wells in twenty-eight counties, with an average flow for each of 2,000,000 cubic feet daily. In the gas region, and in the districts within reach of its pipes, it became for a time almost the exclusive fuel, and also came into use as an illuminant. But by-and-by the supplies of gas began to give out (see GAS-LIGHTING), and the coal supplies resumed their old importance. In 1897 the number of tons of coal raised was 3,706,401, while 65,000 casks of petroleum were obtained. Building-stone and whetstones are plentiful. Devonian, Silurian, and Carboniferous are the chief geological formations. The climate is healthy, but very variable; the winter is severe but short; and summer is hot in the 'Hoosier State,' as Indiana is nicknamed—nobody knows why, though many stories are told.

The principal industry is agriculture, the chief crops being maize, wheat, oats, rye, barley, buck-wheat, potatoes, and tobacco. Some 250,000 gallons of wine are made yearly. The state is surpassed only by Minnesota and Kansas for the amount of its wheat crops, and by Iowa for maize. Flax and sorghum are raised, as are also enormous quantities of apples and peaches. Dairy produce is exported. Wool, honey, maple-sugar, cider, and vinegar are made, and fruit and vegetables are preserved. About a third of the state is still under wood.

The manufactures of Indiana present great variety, and are often important. Among the largest manufacturing concerns of their class in the world are the wagon and plough factories at South Bend, the manufacturing of flour-mill machinery and carriages at Indianapolis, the plate-glass works at New Albany, and the encaustic tile works at Indianapolis. Indianapolis has also the second largest packing establishment, and is at the head of the

sofa-manufacture; Indiana, indeed, turns out more furniture than any other state of the Union, largely made from the valuable timbers of the Wabash and its tributaries. In 1886 there were 11,885 manufactories, with a capital of \$51,490,656. The value of raw material used during the year was \$91,872,291; of products, \$158,562,729; wages and other expenses, \$31,211,152. In 1890 there were 12,384 manufactories with 124,349 workers, producing in the year a value of \$227,000,000. At that date (the census year) the manufactures of the state had increased tenfold in thirty years. The trade is almost wholly internal, though Michigan city has trade with Canada; navigable rivers and canals greatly facilitate commerce. The central position of Indiana compels all main through-lines from the east and west to cross the state. In 1880 there were 4020 miles of railway in operation; in 1895, 10,000. The Wabash and Erie Canal, the largest in the United States (476 miles), has 374 miles in Indiana; and another canal (75 miles) extends from Lawrenceburg to Hayestown. The Ohio is navigable throughout its length within the state, and on it over fifty Indiana steamboats ply; the Wabash is navigable to Lafayette, and its branch, the White River, for about 60 miles.

The population in 1800 numbered 4577 whites and 163 coloured, 135 of the latter being slaves. In 1860 the population was 1,350,428; in 1880, 1,978,301; and in 1890 it was 2,600,000. The cities with over 30,000 of a population in 1890 were Indianapolis (165,436), Evansville (50,756), Fort Wayne (35,392), and Terre Haute (30,217). Great attention is devoted to education. In 1888 the children of school age numbered 756,989, of whom 514,463 were enrolled in the common schools. The number of teachers was 14,204, of school-houses 9882; the revenue for the year was \$5,235,032. There are a state university at Bloomington, the Purdue University and state institute of technology at Lafayette, and the state normal school at Terre Haute, as well as a hundred high schools; instruction at all these is free. Not under state control are 14 universities and colleges, and numerous academies and special schools. In most of the colleges, as in the common schools, the sexes are educated together.

The state is divided into ninety-two counties. The governor is elected for four years. The general assembly, composed of fifty senators and one hundred representatives, meets every two years. Indiana has two senators and thirteen representatives in congress. The judges of the supreme court, five in number, are elected for six years.

History.—Indiana was discovered by La Salle in 1671, and constituted part of New France. In 1763 France ceded the country to Great Britain; by the treaty of 1783 it became a part of the United States, under the general term of the north-west territory, which later was divided into the territories of Ohio, Indiana, Michigan, Wisconsin, and Illinois. In 1816 Indiana was admitted to the Union, and the state government was finally settled at Indianapolis in 1825. By the ordinance of 1787 slavery was prohibited in the territory. The Indian troubles resulting from the influx of settlers culminated in the battle of Tippecanoe (see HARRISON, W. H.) in 1811. Indiana supplied five regiments for the war with Mexico, and during the civil war furnished for the government service 208,367 men, of whom 24,416 were killed or died of disease.

Indianapolis, the capital and largest city of Indiana, is on the west fork of White River, on a level plain, near the centre of the state, 195 miles SSE. of Chicago by rail. It is a regularly-built and beautiful city. Its streets, many of them 100 feet wide, for the most part cross at right angles; but

four main avenues, radiating from a central park, cross the others diagonally. The principal buildings include a handsome new state-house (completed 1888), a fine county court-house, a city hall, a prison for women, a large state asylum for the insane, and other asylums for the blind and deaf and dumb; and the city possesses an imposing monument to the soldiers and sailors who fell in the civil war. It has also two medical colleges, numerous schools, and nearly a hundred churches. Indianapolis is one of the chief railway centres of the United States, fifteen main lines converging here. The trade in agricultural produce is very considerable. Pork-packing is the leading industry, but there are also large flour and cotton and woollen mills, numerous foundries, and manufactories of furniture, carriages, tiles, &c. (see INDEX A). The site of Indianapolis, then covered with dense forest, was selected for the future capital in 1820, and the city was founded in 1821. In 1860 the pop. was 18,113; (1870) 48,244; (1880) 75,056; (1890) 105,436.

Indian Ocean. The Indian Ocean is bounded on the W. by Africa, on the N. by Asia, on the E. by Australia and the Australasian Islands. According to modern geographers it is limited to the S. by the 40th parallel of south latitude, in which region it opens widely into the Southern and Antarctic oceans. It gradually narrows towards the north, and is divided by the Indian peninsula into the Bay of Bengal on the east and the Arabian Sea on the west, the latter sending northward two arms, the Persian Gulf and the Red Sea. Within these limits the Indian Ocean is estimated to have an area of 17,320,500 sq. m.

At the dawn of history the Indian Ocean was known as the Erythrean Sea; the Phenicians are said to have been familiar with this southern ocean at a very early date. Necho, an Egyptian monarch who flourished about 610 B.C., is reported by Herodotus to have sent some of his vessels, manned by Phenicians, into the Erythrean Sea with orders to return by the south of Africa and the Columns of Hercules. Whether or not this voyage ever took place, it appears certain, from their reports as to the position of the sun to the north of them, that these early navigators penetrated far south (see GEOGRAPHY, Vol. V, p. 145). From a very early date there was a coasting trade between India and the Persian Gulf, but the voyage of Nearchus, one of Alexander's generals, from the Indus to the Persian Gulf, is the earliest reliable record of these coasts. Hippalus, an Egyptian navigator who flourished about the beginning of the Christian era, was the first to observe the regular alternations in the direction of the monsoons of the Indian Ocean, and to profit by them to open up a direct route across the high seas from the Red Sea to India. The shore routes were henceforth abandoned, and a fresh impulse was given to voyages into oriental waters. In the 9th century the Arabs made frequent voyages across the Indian Ocean, Soleiman of Sirof being probably the first to cross the Bay of Bengal and pass into the China Sea. In 1486 the Portuguese rounded the Cape of Good Hope, and in 1498 Vasco da Gama reached the coasts of India by the same route. In 1521 the one remaining ship of Magellan's squadron crossed the southern Indian

Ocean in completing the first circumnavigation of the world.

The mean depth of the Indian Ocean is estimated at about 2300 fathoms, or slightly greater than that of the Atlantic (q.v.). The greatest depths are in the eastern part to the south of the equator, where it is estimated that there are fully 50,000 sq. m. with a depth of over 3000 fathoms. Over 13,000,000 sq. m. of this ocean's floor lie between the depths of 2000 and 3000 fathoms.

The area of land draining into the Indian Ocean is estimated at 6,813,600 sq. m., and the annual rainfall on this land is equal to 4379 cubic miles of water. The rivers flowing from the Asiatic continent are by far the most important, and they carry an immense amount of detrital matter into the Bay of Bengal and Arabian Sea, these forming extensive deposits of lime mud. Along the African coasts, in depths from 100 to 1000 fathoms, there are great deposits of glauconitic sands and muds, and on these as well as other coasts there are coral muds and sands, and lime and green muds in the shallower depths. In the deeper parts of the ocean, far from land, there are vast deposits of red clay, Radiolarian ooze, and Globigerina ooze. In the Southern Ocean, towards the Antarctic, the bed of the ocean is covered with a Diatom ooze.

The temperature of the surface waters of the Indian Ocean varies much in different parts of the ocean, and at the same place at different times of the year or states of the wind. In tropical regions the temperature usually varies from 70 to 80° F., and the yearly range is only 7° or 8° F. Off the Cape of Good Hope and off Cape Guardafui, however, the annual range of temperature may be from 20 to 30° F. For instance, sudden and great changes of temperature are often noticed off Cape Guardafui when the wind blows off shore, for in this way cold and deep water is drawn up along the African coast to take the place of the warm surface water which is driven eastward by the wind.

The temperature of the water at the bottom of the Indian Ocean is very uniform and subject to little, if any, annual variation. In the Bay of Bengal and Arabian Sea temperatures of 33·7° F. and 34·2° F. have been recorded at the bottom; these are not more than the fraction of a degree higher than those observed by the *Challenger* in 50° of south latitude. It is certain, therefore, that this deep cold water is slowly drawn into the Indian Ocean from the Antarctic to supply the place of the warm surface currents that are driven southward by the winds. The currents of the Indian Ocean are less constant than in the other great oceans, and are largely controlled by the direction and strength of the monsoons (see MONSOONS). Some of the most characteristic coral atolls and islands are to be found towards the central part of the Indian Ocean, such as the great Maldive group, the Chagos, Diego Garcia, and the Cocos Islands. Almost all the tropical shores are skirted by fringing and barrier reefs. Christmas Island is an unpraised coral formation. St Paul's, Mauritius, Rodriguez, and others are of volcanic origin, while Madagascar, Ceylon, and Socotra are typical continental islands.

Indian Orders. Three British orders of knighthood take their name from India. (1) The Imperial Order of the Crown of India, instituted 1st January 1878, consists of the Queen, certain of her daughters and daughters-in-law, of numerous native Indian princesses, and the wives and other female relatives of the viceroy of India, the governors of Madras and Bombay, and the Principal Secretary of State for India. (2) The Most Exalted Order of the Star of India, instituted in 1861, and enlarged in 1866 and 1878, consists of

the sovereign, a grand-master (the viceroy for the time being), and three classes of members—Knights Grand Commanders (G.C.S.I.), of whom there may be 30; Knights Commanders (K.C.S.I.), of whom there may be 72; and Companions (C.S.I.), 114 in number. The badge of the order is a light blue ribbon with thin white stripes, and the motto 'Heaven's Light our Guide.' (3) The Most Eminent Order of the Indian Empire, instituted in 1878 to commemorate the proclamation of the Queen of England as Empress of India, and enlarged in 1886 and 1887, consists of the sovereign, a grand-master (the viceroy for the time being), and three classes of members—Knights Grand Commanders (G.C.I.E.), Knights Commanders (K.C.I.E.), and Companions (C.I.E.). The motto of the order is *Lapromptis Auspiciis* ('Under the favour of the Empress').

Indian Red, a silicate of iron, imported from the Persian Gulf.

Indians, RED. See AMERICAN INDIANS.

Indian Shot (*Canna indica*), a plant common in almost all tropical countries; a herbaceous perennial, with a creeping root-stock (*rhizome*), and a simple stem, formed by the cohering bases of the large, tough, ovate oblong leaves. It belongs to the natural order Marantaceae. It derives the name Indian Shot from the seed, which is hard, round, and about the size of a very small pea. The seed yields a beautiful red colour. The root-stocks are very large, spongy, and jointed, and are used in Brazil for emollient poultices in tumours and abscesses. The root-stocks of some of the other species of *Canna* are more valuable, yielding the starch called Tons-les-mois.

Indian Territory comprises a portion of the region originally set apart by the United States government as a home for Indian tribes. It is bounded N. by Kansas, from which it is separated by the parallel 37° N., E. by Missouri and Arkansas, S. by Texas, from which it is separated by the Red River, and W. by Oklahoma Territory. The line dividing these two territories is exceedingly irregular, and Oklahoma lies both W. and N. of Indian Territory. Beginning at the N. this boundary is formed by the meridian 96° W., the parallel 36° 10' N., and the meridian 96° 37' 30" W. to the N. Fork of the Canadian River. S. and W. of this stream the line is continued by the meridian 96° 47' W. to the Canadian River, by that river to the meridian 98° W., and thence S. to the Red River. The section of land situated S. of Kansas and E. of Texas and the Public Land Strip, known as the Cherokee Outlet, is also described as a part of Indian Territory, although it is under the jurisdiction of Oklahoma (q.v.), of which it will ultimately become a part. The area, not including the Cherokee Outlet, is 31,000 sq. m.

The surface of the territory consists mainly of rolling prairie land rising gradually from the southeast toward the N. and W. In the south east the surface is broken by low ranges of the Ozark Mountains which cross the Arkansas border. The most important groups are the San Bois and Shawnee. In the south-west are the Arbuckle Mountains. The mineral resources are practically undeveloped, but coal, copper, iron, marble, and building stones are known to exist in considerable quantities. The territory is well watered, and is drained by the Red and Arkansas Rivers and their numerous tributaries. The river bottoms are wide and fertile, subject to overflow in the spring, and usually enclosed between bluffs which rise abruptly to the intervening uplands. The north-eastern part is well wooded, and a belt of forest, known as the 'Cross-timbers,' extends from the Arkansas River to the

Brazos in Texas. The black bear, brown bear, antelope, and deer are abundant; wild turkeys, prairie-hens, and sage-hens also abound.

Indian Territory when first established included all the hitherto unmorganised portion of the Louisiana Purchase, and was designed for occupancy by the tribes then east of the Mississippi. During the years 1833 and 1834 the Creeks, Choctaws, Chickasaws, and Cherokees were removed to their new home. In 1838 the Seminoles were added, and the remnants of several other tribes followed shortly after. Treaties were made by the government, covenanting to maintain the title of the country to the Indian tribes. The original grants extended northward from the Red River, including portions of what are now Kansas and Nebraska, and westward to the 100th meridian. By subsequent treaties with the Indians, the United States acquired control of the country N. of parallel 37°. A strip of land between the parallels 36° 30' N. and 37° N., and between the meridians 100° W. and 103° W., later known as the Public Land Strip, was, after the annexation of Texas, for a time erroneously reckoned as a part of Indian Territory.

In 1866 the United States purchased the western portion of the various grants to be allotted to other Indian tribes or to freedmen. At the same time, the Seminoles, who had parted with their entire domain, purchased a portion of the land ceded by the Creeks. Tribes whose homes were west of the Mississippi have at various times been settled on these lands. By consent of the Indians, part of these lands were in 1889 and 1890 thrown open to white settlers, and the organisation of Oklahoma reduced Indian Territory to its present limits.

The Cherokees, Choctaws, Creeks, Chickasaws, Seminoles, and some of the smaller tribes at or near the Quapaw Agency in the north-east have made considerable progress in civilisation. Schools and churches have been established. There are excellent farms and cattle ranges, and commerce has gained some foothold. The Missouri, Kansas, and Texas Railway crosses the territory from N. to S. Before the civil war the Indians owned negro slaves, and during the war some of the civilised tribes sided with the South, and for a time were considered to have forfeited their lands. The territory comprises three divisions, partly under the jurisdiction of United States courts and partly under tribal jurisdiction. The judicial centre of the first district is at the Quapaw Agency, of the second at McAlester, and of the third at Ardmore.

Population at the census of 1890, 186,490, of whom 177,682 are members of the five civilised tribes (with descendants of former negro slaves), and the remainder are Indians on reservations. See the articles AMERICAN INDIANS, OKLAHOMA, CHEROKEES, &c.

India-rubber. CAOUTCHOUC, or GUM ELASTIC, a substance which, on account of its peculiar properties, is extensively used in the arts. It is found in the milky juices of plants, and most abundantly in the natural orders Moraceae, Artocarpaceae, Euphorbiaceae, Apocynaceae, and Asclepiadaceae. It exists in the milky juice of plants growing in temperate climates; but it is only in tropical and subtropical countries that it occurs so abundantly as to be of economical importance. The principal South American tree is the *Hevea brasiliensis* or *guianensis*, also called *Siphonia elastica*, or *Jatropha elastica*, a Euphorbiaceous tree; also the Mexican *Castilleja elastica*, which is Artocarpaceous. In the East the *Ficus elastica* (of the order Moraceae), akin to the Banyan (q.v.), is a tree of noble proportions, the appearance of whose glossy leaves is well known in Europe from small specimens grown in pots as ornamental plants. Various Apocynaceous trees (Willughbeia, Landolphia, Ureola,

&c.) yield commercial quantities of rubber in Malaya, Borneo, and Central Africa. The name *Caoutchouc* is from a Carib or Central American word *Cachucha*.

Some of the properties of india-rubber must have been known in America at a very early period, because balls made by the Haytiens of the *gum of a tree*, bouncing better than the wind-balls of Castile, are mentioned by Herrera in his account of Columbus's second voyage. In a book published in 1615 Juan de Torquemada mentions the tree which yields it in Mexico, describes the mode of collecting the gum, and states that it is made into shoes; also that the Spaniards use it for waxing their canvas cloaks to make them resist water. More exact information was furnished by M. de la Condamine in 1735. India-rubber was at first known as *Elastic Gum*, and received its present name from the discovery (about 1770) of its use for rubbing out black-lead pencil marks, for which purpose it began to be imported into Britain in small quantities about the end of the 18th century, being much valued by artists, and sold at 3s. the cubic half inch. Even before this time its employment for the manufacture of flexible tubes for the use of surgeons and chemists had been successfully attempted; but it was not till 1820 that its employment began to extend beyond the rubbing out of pencil marks. Its application to the manufacture of waterproof cloth first gave it commercial importance. About the same time a method was discovered of fabricating articles of various kinds by casting india-rubber in moulds. Its elasticity and flexibility, its insolubility in water, and its great impenetrability to gases and fluids in general have now been found to adapt it to a great variety of uses; but for by far the greater number of its applications it is now employed in the vulcanised state.

The india-rubber of commerce is obtained most largely from South America, but considerable quantities are also procured from British India, the Indian Archipelago, the west coast of Africa, and the Mauritius. During the year 1888 the imports of this material into Great Britain were as follows:

From Brazil	cwt.
West Coast of Africa	196,617
Africa, other parts	43,443
United States and Central America	7,352
British India	9,435
Portugal	21,889
Other Countries	11,276
	29,288
Total	229,350

In 1852 the total imports were only 15,269 cwt.; in 1862, 59,703 cwt.; in 1876, 157,509 cwt.; in 1883, 229,101 cwt.; in 1887, 237,511 cwt.; in 1888, 218,171 cwt.; and in 1889, 236,275 cwt. In 1883 the average price per cwt. was 318s.; in 1885, 220s.; in 1887, 228s.; and in 1894, 216s. The value of imports in 1883 was £3,652,817, and in 1888, £2,553,341. In 1894 the import was 302,451 cwt. (including that from Nyassaland and Congo Free State) valued at £3,272,104. India rubber goods worth over £1,000,000 are exported from Britain.

India rubber is sometimes collected by cutting the trees down, which is a very ruinous process, and resorted to mainly that a greater quantity may be obtained. The more usual method, however, is by making simple incisions in the trunks. In a few hours the juice which flows out fills clay basins placed to receive it. It is solidified and dried by various methods, sometimes spread out in thin layers and dried in the sun or the smoke of fires, sometimes (in Central America) coagulated by leaves of a kind of vine. A good tree will yield four ounces of juice daily, and twenty gallons in a season; a gallon producing 2 lb. of good rubber. Adulteration is not uncommon.

Pura india-rubber is the best, and commands the highest price in the market (averaging about 3s. per lb.). The other South American kinds are of fair quality. East Indian rubber, though naturally a fine quality, is often injured by adulteration and careless collecting.

Commercial india-rubber is a tough fibrous substance, possessing elastic properties in the highest degree. Reduced to the temperature of freezing water (32 F.) it hardens, and in greater part, if not entirely, loses its elasticity, but does not become brittle. When heated, as by placing in boiling water, it softens and becomes very much more elastic than at ordinary temperatures, though it does not in any degree dissolve in the water. If suddenly stretched to seven or eight times its original length it becomes warm; and if kept in this out-stretched form for several weeks it appears to lose in great part its elastic properties, and in this condition is readily cut into those thin threads which are used in the *elastic* put in bonnets, &c., and the elasticity of which is readily renewed by the application of gentle heat. Of late years, however, elastic thread is usually prepared with vulcanised rubber. Commercial india-rubber is insoluble in water and alcohol, is not acted upon by alkalis or acids, except when the latter are concentrated and heat is applied, but is soluble in ether, chloroform, bisulphide of carbon, naphtha, petroleum, benzol, and the essential oils of turpentine, lavender, and saffrafs. Many other essential and fixed oils, when heated with rubber, cause it to soften, and produce thick glutinous compounds, especially linseed-oil, which, in the proportion of $\frac{1}{4}$ lb. of the oil to 4 oz. rubber in thin strips of films, yields a solution which, when strained, is of great use in rendering shoes, cloth, &c. waterproof. When heated to 248 F. rubber fuses; and at 600 it is volatilised, at the same time undergoing decomposition, and yields a liquid called *Caoutchoucine*, possessing great solvent powers over india-rubber and other substances.

To purify the raw material it is boiled for some time in large tanks, which softens it and in some measure releases the solid impurities with which it is often mixed. It is then put through powerful machines which masticate and reduce it to shreds, and while undergoing this operation a stream of water is constantly running over it and thoroughly cleansing it from all impurities. It is then rolled out into thin sheets and hung up to dry in a room heated by artificial means, and thus freed from all moisture. Or, after cleansing, the material undergoes a process of kneading under very heavy rollers, which causes the adhesion of the various pieces of rubber to each other, and ultimately yields a mass or block of rubber in which the condensation is so perfect that all air-holes and other cells and interstices disappear. The block of rubber is then cut under water by powerful knives or shears into sheets, from which bands or thread may be obtained. In the manufacture of square threads mere cutting is had recourse to; and the delicacy of the operation may be understood when it is stated that one pound of rubber will yield 32,000 yards of thread. The round elastic thread is prepared from rubber which has been treated with about double its weight of bisulphide of carbon, containing about 5 per cent. of alcohol, which yields a soft material resembling in consistence bread-dough or putty; and this being squeezed through a series of small holes, produces minute round threads, which are first received on an endless piece of velvet, and ultimately on an endless web of common cloth 500 to 600 yards long, during the transit of the threads across which the solvent or bisulphide of carbon evaporates, and

leaves the india-rubber. When it is wished to weave these threads into cloth they are wound upon bobbins, taking care to stretch the rubber as much as possible, so as to deprive it for the time being of its elasticity; and, after it has been woven into the cloth, a hot iron is passed over the fabric, and immediately the rubber resumes its elasticity.

The method for making waterproof clothing or 'Mackintoshes,' the first application of rubber on a large scale, suggested by Professor Syme in 1818 was patented in 1823 by Charles Macintosh of Glasgow. In this manufacture the caoutchouc has to undergo many and varied processes. It is first reduced to a solution with naphtha or other solvent, and it is then amalgamated with other ingredients according to the nature of the material it has to be applied to. It is then spread on the surface of the cloth, a process formerly done by hand, but now by means of spreading machines, which apply it in very thin coats, so thin that with pure para proofing as many as twelve coats are spread to make the cloth air-proof, but so thin is each coat that the twelve only measure one ninety-sixth part of an inch; for ordinary waterproof purposes, however, five or six are generally sufficient. For double textures the cloths are then pressed together between heavy rollers. These cloths are all vulcanised, and this can be performed by a number of processes—by the 'cold' process, by vaporising, by steam, and by dry heat. The garments are then cut out from the cloth, and fastened together by means of pure rubber cement, which make the edges adhere.

The variety of garments now made up are almost endless, and every year the demand for them in fashionable designs and cloths is increasing.

Vulcanised or Solid India-rubber.—Pure india-rubber is now used only to a limited extent in the arts, but it is applied in the vulcanised state to a very large extent. The remarkable change which caoutchouc undergoes when mixed with sulphur and heated, according to circumstances, from 240° to 310° F., was discovered by Charles Goodyear, in America, in 1834-44, and independently, about the same time, by Mr Thomas Hancock, in England. In the process of vulcanising, the rubber, as a preliminary step, is either torn into shreds or crushed into thin pieces by machinery, and afterwards washed. There are two principal kinds of vulcanised rubber, one hard and horny in its texture, the other soft and elastic. In the case of the former the caoutchouc is mixed with about one-third of its weight of sulphur, and heated for several hours, the temperature finally rising to fully 300° F. For the soft kind of vulcanised rubber, on the other hand, a much smaller proportion of sulphur is required—viz. from 2½ to 10 per cent., and the heat to which it is subjected in the vulcanising chamber is considerably less. Usually, too, with this latter kind, the articles are made before the rubber is heated. The sulphur is commonly added in the ground state, but sometimes the rubber is treated with some solution containing this element, such as the bisulphide of carbon.

Although sulphur is the only essential ingredient required for vulcanising rubber, yet other substances are usually added. Thus, in the case of machinery belting, pipes, and some other articles, the silicate of magnesia (French chalk) is used to prevent adhesiveness. Litharge, or carbonate of lead, again, is frequently mixed with the rubber and sulphur for certain purposes; but there is really a long list of materials more or less used in preparing different qualities of vulcanised caoutchouc, each manufacturer using mixtures the exact nature of which he is careful not to divulge. Asphalt, tar, lime, lampblack, whiting, rosin, sulphide of

antimony, and ground cork are some of the ingredients most commonly employed in this way. Belting for machinery and some kinds of tubing are formed of alternate layers of canvas and vulcanised rubber.

Natural caoutchouc, as already stated, is elastic, cohesive, impervious to gases, insoluble in water, and resists many chemical reagents; but it loses its elasticity by cold, softens by heat, and is destroyed by many fixed oils. After being vulcanised caoutchouc has its elasticity greatly increased, is not hardened by cold, and does not soften or become viscid at any temperature short of its absolute decomposition. Besides, it is barely soluble in turpentine, naphtha, and the other solvents of pure caoutchouc; nor does oil readily penetrate or soften it. Very often, however, the natural oil in some cloths, or oils used in manufacture, tend to make the rubber decay, and this has often caused rubber-manufacturers a large amount of trouble.

It would be a hopeless task to attempt to specify the many useful purposes to which vulcanised caoutchouc is applied, even if we had the space to spare. From the year 1843, when it was first made, to the present time the various patented applications of it must be thousands in number. The mere abridgments of the specifications connected with this material, issued by the English Patent Office, form a thick volume. Under the head GOLOSRES will be found a brief description of the process of making india-rubber shoes. Both coats and shoes of this material have, however, the objectionable property of preventing the escape of moisture from the skin. Belting, linkers, wheel tires, washers, valves, pipes, fire-hose, and other engineering appliances form a large branch of the rubber-trade. For medical and surgical purposes many articles are made of this material. Of such an apparently trivial matter as vulcanised rubber thread one English firm turns out about 3000 lb. per day, and another single small article—viz. tobacco-pouches—is made in another factory at the rate of 3000 per diem.

Hard vulcanised rubber, termed vulcanite, and sometimes ebomite, is made into a great many small articles, such as combs, chains, bracelets, boxes, penholders, paper-knives, knife-handles, buttons, &c., as a substitute for materials like horn, bone, ivory, and jet. Like these substances themselves, it is formed into various objects by moulding, cutting, carving, polishing, and other processes. Vast numbers of these articles are now sold. The black colour of vulcanite ornaments has still a tendency to turn gray, but the brittleness which was a fault of combs made of it a few years ago seems to be overcome. With respect to objects of considerable size, vulcanite has been made into furniture, ornamental tiles, and even rails for railroads and paving for footpaths, for which latter purpose it suits admirably. A kind of vulcanite is now very largely employed as an insulator in electric cables.

India-rubber when melted at 308° F., and mixed with half its weight of slaked lime, forms a useful cement or lute, which can be easily loosened, but it will dry and harden if red lead is added. A very tenacious glue is formed by heating caoutchouc, coal-tar, and shell-lac together. It forms an ingredient in some special kinds of varnishes, and it also improves the lubricating qualities of mineral oils when a small quantity is dissolved in them.

In Great Britain some of the large india rubber factories employ over 1000 hands, and smaller works are springing up all over the country. The exports are sent all over the world, principally to the Continent, North America, and Australia. The duty levied on this class of goods is prohibitive of the expansion of the trade with the United States. The manufacture of india rubber is also carried on

extensively in the United States and France. In most rubber factories a large number of the work-people are females; and, as no great skill is required on the part of the operatives engaged in some departments, employment in such works has proved a boon to many persons who have never learned a trade.

The high price of raw india-rubber has led to many attempts to produce a substitute, but none of them equal in durability the pure caoutchouc.

Indicator-diagram, a diagram drawn on an *indicator-card* by the pencil of the *indicator* of an engine at work. The object in view is to ascertain the relations between, and also the product of the varying pressure and the corresponding variations of volume of, the working substance—steam, explosive gas mixture, hot air, or other material. The latter, the variations of volume, are, in a cylinder, well represented by the movements of the piston; the former, the varying pressure, may be followed by making the steam, &c. press out the piston of a small side-cylinder against the resistance of a spring. If a pencil be attached to this piston it will mark on a piece of paper or card held in contact with the point a straight line traced and retraced with varying velocity. If the steam be shut off from this side-cylinder the pencil assumes the position of 'no pressure.' If now, on the other hand, the piston of the main cylinder be made to draw the paper or card past the pencil point in a direction at right angles to the former, the varying velocity with which a straight line is traced and retraced on the paper will reproduce the varying velocities of the main piston itself. If these two actions be now combined the pencil will move, say, up and down, while the paper will oscillate or be unrolled backward and forward. The pencil-point will accordingly describe upon the paper an irregularly-curved figure which will, in uniform working, be a closed curve, and will always tend approximately to reproduce itself during each successive cycle of the engine. Upon the scales on which the linear traces of the pencil represent, in directions at right angles to one another, the variations of pressure and the piston-movements respectively, the *area* enclosed by this curve will represent the work done by the engine during each cycle; and its *form* enables the actual pressures and volumes of the working substance to be traced out for each successive portion of the cycle, and thus enables the working of the engine to be carefully studied in detail. For examples see *Holmes, The Steam-engine*; and *Dugald Clerk, Gas-engines*. See article GAS-ENGINE for diagrams.

Indiction, a period or cycle of fifteen years, the origin of which is involved in obscurity, but which was originally a fiscal term. It began to be used in reckoning time, chiefly by ecclesiastical historians, during the life of Athanasius; it was afterwards adopted by the popes, who still continue to use it, and through whose influence it came to be so generally employed during the middle ages that the dates of charters and public deeds of this era are expressed in indictions as well as in years of the Christian era. The first indiction is supposed to have commenced on September 24, 312, the day of Constantine's victory over Maxentius. If we reckon backwards to the commencement of the Christian era it will be seen that 1 A.D. does not correspond to the 1st, but to the 4th year of an indiction—hence, *if to any given year of the Christian era 3 be added, and the sum divided by 15, the remainder will give the position of that year in an indiction*—thus, 1890 A.D. was the third year of an indiction. Of course such a method of marking time was necessarily incomplete, for it included no statement of the number

of indictions which had elapsed since the first adoption of that method of computation.

Indictment. See CRIMINAL LAW.

Indies. See EAST INDIES, and WEST INDIES.

Indigestion, or DYSPEPSIA, properly includes only such derangements of the digestive process as do not depend on any recognisable structural change. But it is very common to apply the term loosely to any digestive disorder, whatever its cause may be. In this sense dyspepsia is a symptom of a multitude of diseases, in the description of which, when it is sufficiently important, it will be found noticed. Functional dyspepsia, the dyspepsia of otherwise healthy people, is what will be considered here. Of this there are two chief varieties, the *atonic* and the *irritative* or *acid* dyspepsia. The former is caused by deficient secretion of the gastric juice and diminished movement of the stomach walls, and it is often associated with a want of vitality in the system. The latter is frequently found in persons of vigorous and robust frame and of active habits; and in many cases it is to be looked upon as the result of an excess of digestive activity leading to the accumulation of an abnormal amount of acid products in the stomach, especially toward the end of digestion. This form is more common in men than in women, and is rarely met with before adult life.

The symptoms of dyspepsia differ considerably in different individuals. The appetite is often good, and sometimes voracious, but it may be deficient. For some time after eating there may be no discomfort; but sooner or later pain comes on in the region of the stomach, at first dull, afterwards more severe. A feeling of fullness and distension follows, accompanied by flatulent discharge and the eructation of a sour liquid. The discomfort may sometimes deepen into nausea and vomiting. The pain occasionally shoots up towards the shoulders, and may run down the left arm, like the pain of angina pectoris. From this, however, it may be distinguished by the fact that it comes on after food. The pain is due partly to over-sensitiveness of the stomach, and partly to the irritation of its acid contents, especially of butyric acid. When the pain is of a paroxysmal character it is called Gastralgia or Gastrodynia. Cardialgia or heartburn, and Pyrosis or water-brash, are common symptoms which have also been dignified with special names. The former is said to be caused by the irritation of the upper end of the stomach by the fumes of its acid contents, while the latter is essentially an abortive act of vomiting accompanied by a gush of saliva (Roberts).

In the treatment of indigestion the diet should be strictly regulated. The experience of the patient is often a better guide as to details than all the dicta of the faculty. The food should be properly cooked and well masticated, and the interval between meals should neither be too long nor too short. Where the appetite is feeble food must be taken frequently, in small quantities at a time; and it is often advantageous to use substances which have been partially digested with pancreatic or peptic extract. A mixture of animal and vegetable food is in general more easily digested than either kind taken exclusively. Mutton, fowls, and game are the most digestible kinds of animal food; roast beef is to be preferred to boiled; but pork and all cured meats, such as salted beef, ham, tongue, and all greasily-cooked dishes should be avoided. Cheese, pastry, raw vegetables, such as salads, cucumbers, &c., must also be prohibited. As a rule, dyspeptic persons would probably do well to avoid all stimulating drinks; but in some cases a little cold, weak

brandy and water, or a glass of old sherry, or a little bitter ale may be taken with advantage.

It is of great importance to attend to the bowels (see CONSTIPATION). Regular exercise in the open air should be enjoined. Riding exercise is of special service where the liver is out of order. In some cases change of scene and occupation is of more benefit than anything else. In the medicinal treatment of dyspepsia a host of remedies are in vogue. Acids (especially nitro-hydrochloric acid), either before or after meals, bitters (such as quinine, calumba, gentian, quassia, and hops), and nux vomica increase the appetite and aid digestion. Pepsin is a valuable adjuvant. Nausea and vomiting may be checked by hydrocyanic acid, chloroform, and creosote in very small doses, or by ice and alkalis. Hyposulphite of soda, sulphurous acid, and carbolic acid act well when the vomiting depends on fermentation. For flatulence, bismuth, cardamoms, charcoal, sulpho-carbolate of sodium, hot water, and many other remedies are in use. For the pain in the stomach the subnitrate of bismuth in drachm doses has a well-merited reputation. Spirits of chloroform, followed by hot water, may also be used. The subcutaneous injection of morphia gives effectual relief for the time, but it should not be employed without advice. In nervous dyspepsia, hydrochlorate of cocaine in doses of a quarter of a grain has lately been used with success.

Indigirka, a river in the Siberian government of Yakutsk, rises in a western off-set of the Stanovoi Mountains, and, after a northerly course of 870 miles through a desolate and frozen desert, falls into the Arctic Ocean in 71° N. lat. and 150° E. long.

Indigo (Gr. *Indikon*, 'Indian drug'), a most important vegetable dyestuff, yielding a beautiful blue and very durable dye, the basis also of the best black dye in woollen cloths. It has been used in India from a very early period, and was imported thence by the ancient Greeks and Romans, but was lost to Europe during great part of the middle ages—although the cultivation of the plant and preparation of the dye were described by Marco Polo in the 13th century—until re-introduced by the Dutch about the middle of the 16th century.

Indigo Plant (*Indigofera tinctoria*);

a, raceme of seed-pods. (From Bentley and Friemen.)

The plants that yield the best indigo belong to the genus *Indigofera*, of the natural order Leguminosae, sub-order Papilionaceae. *Indigofera tinctoria* is the species most generally cultivated in India. Central American and West Indian indigo is the produce of *I. anal* and *I. quatinola*.

Indigo is, however, obtained from plants of other genera, particularly from *Wrightia tinctoria* (natural order Apocynaceae), East Indies; *Baptisia tinctoria* (natural order Leguminosae), North America, which yields indigo of a pale colour and very inferior quality; *Tephrosia tinctoria* (natural order Leguminosae), Malabar; *T. Apollinea*, Egypt

and Nubia; *Marsdenia tinctoria* (natural order Asclepiadaceae), in Sylhet; and *Polygonum tinctorium* and *P. Chinense* (natural order Polygonaceae), China and Japan.—In times when East Indian indigo was not known, or was brought to Europe only in small quantity, the same dyestuff was obtained from Wood (q.v.).—A coarse kind of indigo, called Bastard Indigo, was also at one time made in North America from the young shoots of *Amorpha caerulea* and *A. fruticosa* (natural order Leguminosae).

In cultivating the indigo plant the seed is sown in drills about one foot apart at the beginning of the rainy season. Hoeing and weeding require to be assiduously attended to prevent the plants from being overpowered by weeds. The first crop is obtained in about three months after sowing. The stems are cut as the plants begin to flower, and quickly shoot up again, and in this way two and sometimes three crops are taken from the same plants in one season. Immediately the crop is cut it is tied in bundles and carried to the steeping vats to undergo the process of extracting the indigo; for an account of which see DYEING.

Commercially speaking, indigo may be said to be the produce of India and Central America, as these are the only localities which supply the recognised form of the article. Bengal is the chief seat of indigo produce; and Bengal indigo is the most esteemed. From 1740 till the civil war indigo was much grown in Georgia and South Carolina, but thereafter the United States depended on imported indigo. British imports fluctuated from above 1,000,000 cwt. (value £2,500,000) to under 60,000 cwt. (value £950,000) in the last years of the 19th century, when the trade was menaced by German artificial indigo. The essential constituent of natural indigo is *Indigotin* or *Indigo Blue* (C₁₆H₈N₂O), but it likewise contains *Indigo Brown*, *Indigo Red*, and other ingredients. In 1878 Baeyer of Munich announced the successful synthesis of an artificial indigo from phenylacetic acid, a coal-tar product; and Nenmann of Zurich made the synthesis commercially practicable. By 1897 Germany supplied its own wants from this source; by 1901 one company at Ludwigshafen produced as much as could be grown on 230,000 acres of Indian land, and it was a question whether the growers of natural indigo in Behar and other parts of Bengal would be able to compete with the German aniline companies (see ANILINE, DYEING, SYNTHESIS). The costly so-called *green indigo* of China, used by Chinese artists and for silk-dyeing, is obtained from a tree called *hau-li*.

Indigo Bird (*Cyanospiza cyanea*), a North American bird of the Finch family (Fringillidae), a native of the United States, as far north as the Missouri, which it visits in summer, and of Central America, where it spends the winter. It is about 5½ inches in length, of a beautiful blue colour, variously tinged and shaded. It frequents open places on the edges of woods, and has a very sweet song.

Indium, a metal (trivalent; atom. wt. = 113.1), soft, silver-white, malleable, soluble in hydrochloric acid; its sulphate forms alums with alkaline sulphates. It was discovered in 1863 by Reich and Richter in Freiberg zinc-blende, through observing in its spectrum two characteristic indigo-blue lines.

Individualism. See SOCIALISM.

Indo-China, the eastern of the two great Asiatic peninsulas which extend southwards into the Indian Ocean, sometimes called Further India. It is washed on the east by the Gulfs of Tonquin and Siam and the Chinese Sea, and on the west by the Bay of Bengal. Accounts

of the various states which it embraces will be found under the headings ANNAM, BURMA (with map), CAMBODIA, COCHIN-CHINA, MALACCA, SIAM, and TONQUIN.—The term *Indonesia* is sometimes used for the Indian Archipelago, the islands to the south-east of Asia.

Indo-Europeans. See **ABYAN.**

Indore, a Malhatta principality of India, comprising the territories of the Holkar dynasty, and consisting of several detached tracts, covers an area of 8400 sq. m. The bulk of it lies between Sindhia's dominions on the north and Bombay Presidency on the south, its length from north to south being 120 miles, and its breadth 82. It is traversed from east to west by the Nerbudda, which almost bisects it; by the Vindhya Mountains, their loftiest point within its limits being 2500 feet above the sea; and by the Satpura Mountains. Principal products, poppy, cotton, tobacco, wheat, rice, millets, &c.; principal industries, cotton and opium manufacture. Pop. (1891) 1,099,990. The Vindhya and Satpuras have from time immemorial been the home of the Bhils (q.v.), the wildest of the aboriginal tribes in India. The Holkar State Railway connects the Rajputana railway-system with that of Bombay. The climate is sultry, the thermometer ranging from 60° to 90° F. in the shade. The state was founded about the middle of the 18th century by Malhar Rao, a soldier of fortune, who served the Peshwa. In 1818 the ruler of the Holkar dominions was reduced to the position of a feudatory prince of the British Indian empire. He keeps up an army of 8000 men.

Indore, the capital of the Maharaja Holkar's dominions, is situated in 22° 42' N. lat. and 75° 54' E. long., 1786 feet above sea-level. Pop. (1891) 92,329, mostly Hindus. During the revolt of 1857, though the maharaja remained faithful to the British government, his troops mutinied on 1st July, holding their prince a prisoner in his own palace, and butchering many Europeans in cold blood. The town dates only from 1770. Close to the town is the district specially set apart for the residence of the Governor-general of India's agent for Central India. Within this district stands a celebrated European hospital.

Indorsement, the term generally used to denote the writing of the name of the holder on the back of a bill of exchange or promissory note, on transferring or assigning it to another. Signing the name 'A. B.' alone is a blank indorsement; and if the transferee is named it is an indorsement 'in special' or 'in full.' The usual form is 'Pay C. D. or order. (Signed) A. B.' In Scotland it is 'Pay the contents to C. D. or order. (Signed) A. B.' When personal liability is to be avoided the words 'without recourse' are added, and in this case no demand can come back on the indorser, who would otherwise be liable. The word indorsement is also frequently used in English law to denote any matters written or indorsed on the back of writs or deeds, as indorsements on declarations, on writs of summons, &c.

Indra, the name of one of those Hindu deities that were worshipped more especially in the Vedic period of the Hindu religion, but enjoyed a great legendary popularity also in the Epic and Puranic periods. In these Rig Veda hymns which form the oldest portion of Vedic poetry Indra is a mighty ruler of the bright firmament, and his principal feat is that of conquering the demon *Vritra*, a symbolical personification of the cloud which obstructs the clearness of the sky and withholds the fructifying rain from the earth. All his wonderful deeds are performed by him merely for the benefit of the good, which, in the language of

the Veda, means the pious men who worship him in their songs, and invigorate him with the offerings of the juice of the Soma plant. He is therefore the 'lord of the virtues,' and the 'discomfiter of those who neglect religious rites,' and at the same time he has all the attributes of a warlike god, and is invoked as the destroyer of cities. During the Epic and Puranic periods, where ethical conceptions of the divine powers prevail over ideas based on elementary impressions, Indra ceases to enjoy the worship he had acquired at the Vedic time, and his existence is chiefly upheld by the poets, who, in their turn, however, work it out in the most fantastic detail. A remarkable trait in this legendary life of Indra is the series of his conflicts with Krishna, an incarnation of Vishnu, which end, however, in his becoming reconciled with the more important god. When represented in works of art Indra is generally seen riding on his elephant; and where he is painted he is covered with eyes.

Indre, a department of France, formed principally out of the western portion of the old province of Berry, lies immediately south of the department of Loir-et-Cher. Area, 2623 sq. m., of which about four-fifths are in tillage and pasture. Pop. (1872) 277,693; (1886) 296,147; (1891) 292,868. It is quite flat, and well watered by the Indre (which flows, from the department of Creuse, 152 miles north-westward to the Loire) and the Creuse. It contains three well-marked districts—a stony, woody region with sandy soil in the south, a fertile agricultural region in the east, and in the north-west a region of moors, marshes, and ponds, interspersed with forests. The more notable products are wheat, oats, potatoes, turnips, fruits, and wine. The sheep are excellent as food, and produce first-rate wool. Much poultry is reared. The principal industries are ironworks and manufactures of cloth, paper, leather, and porcelain. The department is divided into four arrondissements—Châteauroux, Le Blanc, Issoudun, and La Châtre. The capital is Châteauroux.

Indre-et-Loire, a department of France, formed chiefly out of the ancient province of Touraine, is crossed by the Loire from N.E. to S.W. Area, 2360 sq. m.; pop. (1872) 317,027; (1886) 340,921; (1891) 337,298. It is watered by the Loire and its tributaries, the Cher, Indre, and Vienne, all of them navigable. The valley of the Loire is very fertile, studded with orchards and gardens and vineyards; it is called the 'garden of France.' South of this lies the monotonous but productive plateau of St Maure, north of it the sterile region of Gâtine. The products include grain, wine (about 22,000,000 gallons annually), fruits (especially plums), and hemp. The industry has never recovered from the blow struck by the Edict of Nantes. The chief manufactures are powder, files, cloth, paper, and leather. The department is divided into the three arrondissements of Tours, Chinon, and Loches; capital, Tours.

Induction, one of the great processes of scientific discovery and proof. It is the operation of *discovering* and *proving* general propositions; while deduction, on the other hand, is the method of *applying* general propositions once discovered to particular cases considered to be included within their scope. By induction we establish the law that heat expands bodies; by deduction we apply it to explain why a clock goes slower in summer than in winter, owing to the changes of the length of the pendulum. It should be mentioned that what has been called *perfect* induction—the observation of *all* the instances and a statement of the result in one general proposition—is not by Mill or the moderns recognised as proper induction at all.

Induction is the process of real inference in other words, by it we proceed from the known to the unknown; or from a limited range of facts we affirm what will hold in an unlimited range. All things that we do not know by actual trial or ocular demonstration we know by an inductive operation. Deduction is not real inference in this sense, since the general proposition already covers the case that we apply it to; in a proper deduction the conclusion is more limited than the premises. By the inductive method we obtain a conclusion much larger than the premises; we adventure into the sphere of the unknown, and pronounce upon what we have not yet seen. Nothing is more common than the making of bad inductions, and accordingly it is now considered a part of logic to lay down the rules for the right performance of this great operation. For the principles and rules of induction, see Mill's *Logic* (book iii.), Fowler's *Inductive Logic*, and Venn's *Principles of Empirical or Inductive Logic* (1890); and see the article LOGIC.

Induction is a term used in England to denote the investing or giving possession of a benefice to a clergyman. This is done by a mandate from the bishop to the archdeacon (in some places the dean and chapter) to make the induction. The inductor takes the clergyman by the hand, and lays it on the key of the church-door (or some part of the church itself), then opens the door and causes him to enter the church alone, and to toll one of the bells as a public notification to the parishioners. The incumbent's possession of the benefice is completed by 'reading himself in'—i.e. reading, generally on the following Sunday, the Thirty-nine Articles, and immediately thereafter making a formal declaration of assent to their doctrine, and giving a pledge of his conformity to the rules of the church.—In Scotland the presbytery inducts the minister.

Induction, in Electricity and Magnetism, is a term of various application. In every case, however, there is a certain idea present—the idea, namely, of an effect produced at an apparent distance from the producing cause, the effect being essentially a reproduction of the cause. More accurately stated, induction is the name of a method or mode by or in which a particular electric or magnetic condition is made to pass from one material system to another without the intervention of any obvious material connection. Thus, in static electricity a metallic body or other conductor brought into the neighbourhood of an electrified body becomes itself electrified by induction. Similarly, a piece of iron or other magnetisable metal, when brought near a magnet, or, more generally, when brought into a magnetic field, becomes itself magnetised by induction. Indeed, according to Faraday's view, induction is the essential feature in all electric and magnetic interaction. These two fundamental cases of induction will be found treated in full under ELECTRICITY and MAGNETISM.

There is, however, a third and very important group of electric and magnetic phenomena to which the name induction belongs. These were discovered by Faraday, and will be treated in a general way under MAGNETISM. The essential peculiarity of this class of induction phenomena is the production of electric currents in conductors or circuits in which there exists no source of electrical energy. These induced electric currents are in all cases the result of some magnetic change in the region occupied by the conductor. This magnetic change may be produced by the approach or withdrawal of a magnet; or it may be produced by the motion of the conductor in a constant

magnetic field; or it may be due to variations of primary currents in neighbouring conductors, or even in the conductor itself. In this last case the variations of these primary currents cause corresponding variations in the magnetic fields existing with them, so that the induced current can always be explained in terms of a magnetic change. According to Ohm's Law (see ELECTRICITY), the strength of a current flowing through a given circuit depends on the electromotive force which excites the current, and on the resistance of the circuit through which the current is made to flow. In the case of induction of currents the electromotive force is directly due, and is measured in terms of, the rate of change of the number of lines of magnetic force embraced by the circuit; and this rate of change depends on the geometrical form of the circuit and on its space relations to the magnetic field surrounding it. Thus the induced current depends on three things—viz. the form of the circuit, the varying space relations of the circuit and the magnetic field, and the ordinary ohmic resistance of the circuit.

One of the readiest ways of producing induced currents is to have two coils of wire, one placed inside the other, and to pass through the inner or *primary* coil a current of varying strength. At every variation of the primary current a current is induced in the outer or *secondary* circuit. The direction of the secondary current depends on the manner of change of the primary. If the primary current is decreasing in strength, the induced current in the secondary circuit flows in the same direction as the primary in its circuit; but if the primary current is increasing, the secondary current flows in the reverse direction. The best effects are produced at the 'making' and the 'breaking' of the primary circuit; for by these operations the primary current is made to have its greatest variations. This is the principle of action of the *Rohmkoff Induction Coil*, one of the many forms of which is shown in the figure. The coils are wound, the primary inside the secondary, on the

portion marked W. The battery wires, attached to the binding screws, *p, n*, are brought into connection with the terminals of the primary coil by means of the commutator, C. The terminals of the secondary coil are fixed to the brass heads of the glass pillars, P, P, which are furnished with pointed rods capable of universal motion. The true way of looking at the action of this instrument is to regard the primary current as the source of a magnetic field within and around the coils. To intensify the magnetic field it is usual to introduce a soft iron core into the centre of the coils. In virtue of magnetic induction this iron core, under the influence of the magnetic force due to the primary current, becomes powerfully magnetised, and the magnetic field within the coil greatly increased. When the primary current is interrupted the iron core loses nearly all its magnetism, and accompanying this great decrease in the strength of the magnetic field an intense induced current flows in the secondary circuit. Now

it is only when the magnetic field is varying that the induced electromotive force exists; and, since in a given secondary circuit the total current induced is proportional to the total change in the magnetic field, it follows that the more abrupt this change the more concentrated will be the flow of the secondary current.

In the induction coil matters are so arranged that the induced current is sufficiently concentrated to pass across a considerable air-space, which really forms part of the secondary circuit. By taking the terminals of the secondary circuit in our hands we may make ourselves part of this circuit, and experience the curious throbbing sensation of a galvanic shock. Or we may attach the terminals to the platinum wires of a Geissler tube, and produce the beautiful effects of electric discharge through gases in a state of great rarity. In most forms of induction coil the primary current is broken and made automatically, the varying magnetic strength of the iron core being used for this purpose. When the primary current passes, the iron core becomes a powerful magnet, and attracts a small iron disc set opposite one end. By means of a simple form of lever attachment this disc when so moved interrupts the primary circuit. The current then ceases to flow, the iron core loses most of its magnetism, and the small iron disc thus freed returns to its original position. With this return of the disc the primary circuit is again completed, the current flows as before, and the same order of effects is repeated, and so on indefinitely. In the secondary coil there is, of course, a possible induced current at make as well as at break. But, as in such instruments the corresponding magnetic change is not nearly so rapid at make as at break, the induced current is not so concentrated. Hence, practically, in working with an induction coil we have to do only with the induced current due to the interruption of the primary circuit.

The Telephone (q.v.) is an instrument whose action depends largely upon the laws of electro-magnetic induction; and in the same category we may include the induction balance of Professor Hughes, which illustrates in a marvellous way the sensitiveness of a variable current flowing in a circuit to the presence of a small piece of metal or other conducting material.

Indulgence, in Roman Catholic theology, means a remission, by church authority, to a repentant sinner of the *temporal* punishment which, in the Catholic theory, remains due after the sin and its eternal punishment have been remitted. By the discipline of the first centuries a severe course of penitential observance was exacted of all who fell into any grievous crime, especially apostasy, murder, and adultery, such sinners being excluded from church communion for various periods, in some cases even till the hour of death. These penitential observances, which Protestants regard as purely disciplinary, were designed, according to the Catholic view, as an expiation on the part of the penitent for the *temporal* punishment which, after sin and the *eternal* punishment due to it have been remitted by God, still remains to be undergone; and some of the most acrimonious of the early controversies, the Montanist and the Novatian, arose as to the power of the church to relax these penitential observances, and to admit grievous sinners to communion. These ancient relaxations (of which they regard that referred to in 1 Cor. v. 5 and in 2 Cor. ii. 10 as a type) are considered by Catholics as examples of the modern indulgence; and the practice which grew up in the 3d and 4th centuries, and which even then was carried to great extremes, of granting such relaxations on the

recommendation of martyrs or confessors, is held by Catholic theologians to be an illustration of that principle of vicarious atonement according to which, in the theory of indulgences, the church is supposed to supply from the inexhaustible treasure of the merits of Christ, and of the 'supererogatory' works of the saints, what may be wanting to the completeness of the atonement of the less perfect but yet truly penitent sinner to whom she grants the indulgence. That this practice of relaxation, whatever may have been its real import, was to be used according to the judgment of the bishop as to the disposition of the penitent, is expressly laid down by the Council of Ancyra in 308 and by that of Nice in 325. In all cases, however, the person granting the relaxation was to impose certain good works as a partial substitute for the penalty which had been relaxed; and among these works, which had at first been purely personal, came by degrees to be included money payments for certain religious or charitable objects, as the building of a church or the foundation of a monastery or hospital.

The name indulgence appears to have originated late, the first recorded instance of its use being by Alexander II. in the 11th century; but the institution itself is found in full development during the wars of the Crusades, the serving, or the contributing to service in which, 'provided it were for devotion alone, and not from motives of greed or of glory,' was accepted in the Council of Clermont 'as an equivalent substitute for all penance.' Such an indulgence was called 'plenary;' where a portion only of the penitential works was relaxed it was called 'partial;' and in order to put a bar to their excessive multiplication and to other abuses Innocent III. declared the power of granting 'plenary indulgences' to be reserved to the pope alone, bishops being only authorised to grant the 'partial' or limited indulgences described above. The fourth Lateran council condemns the 'indiscreet and superfluous' granting of indulgences; and among the abuses which grew up in the church during the western schism one of the most remarkable was the lavish dispensation of indulgences, in the granting of which the contending popes rivalled each other in prodigality. The last extreme, however, was not reached until the beginning of the 16th century, when, with a view to raising the funds necessary for the erection of the great church of St Peter's at Rome, the pope, Leo X., published a plenary indulgence, the principal condition for the gaining of which was a contribution to this work. Catholic historians contend that in itself such a condition was perfectly justifiable, and that if duly explained to the people it might be lawfully and even meritoriously complied with; but they admit that Tetzel and many more preachers of the indulgence in extolling its natural effects went to indefensible extremes, and that, even making the fullest allowance for exaggeration, it cannot be denied that grievous abuses both of doctrine and of practice were committed in Germany and in Switzerland. Hence the decree of the Council of Trent, while it affirms that the use of indulgences, as being 'most salutary for the Christian people, and approved by the authority of councils, is to be retained in the church, yet orders that 'in granting them moderation be observed, lest by excessive facility discipline may be enervated.' Upon the special instructions of this council all the modern legislation on the subject of indulgences has been founded; but as the decree of the council does not explicitly declare what is the precise effect of an indulgence it is further explained by Pope Pius VI., in his celebrated bull *Auctorem Fidei*, that an indulgence received with due dispositions remits not alone the canonical

penance attached to certain crimes in this life, but also the temporal punishment which would await the penitent after death to be endured by him in purgatory.

From the above explanation it will be gathered that Catholics do not understand by an indulgence a remission of sin, much less a permission to commit sin or a promise of forgiveness of future sin. They contend, moreover, that, since the benefit of an indulgence can only be enjoyed by a sinner who has repented of sin and resolved to embrace a new life, the imputation of introducing laxity of principle and easy self-indulgence is entirely unwarranted. And although for the most part the good works which are required as the condition of obtaining indulgences may appear easy and even trivial, yet the one indispensable preliminary—sorrow for sin and sincere purpose of amendment—involves the highest effort of Christian virtue.

See vol. iii., H. C. Lea's *History of Auncular Confession and Indulgence* (1896).

THE DECLARATION OF INDULGENCE, proclaimed by James II. in 1687, promised to suspend all laws which tended to force the consciences of his subjects. His real aim was, of course, merely to relieve the Roman Catholics; hence the declaration was very unpopular, and the refusal of the Seven Bishops to command their clergy to read it from their pulpits was but the culminating point of universal public dissatisfaction. Two similar indulgences in English history were those issued by Charles II. in 1662 and 1672, both of which were equally displeasing to the dissenters alike in England and Scotland, who declined to share their toleration with their Roman Catholic fellow-subjects.

Indus (Sansk. *Sindhu*), a river of India, which rises in an unexplored region in Tibet, near the sources of the Sutlej, in 32° N. lat. and 81° E. long. The precise spot is said to be 16,000 feet above the level of the sea, and to be on the north side of the Kailas Mountain. Its general course is at first towards the north-west, through Tibet and Cashmere. Here it is known as the Singh-ka-bab. In the north-west of Cashmere, in about 34° 50' N. lat. and 74° 30' E. long., it turns abruptly southwards, and follows that direction, varied by stretches to the south-south-west, right down to the sea. In the mountains its current is very rapid; the river passes through deep, wild gorges (one near Iskardoh, in north-west Cashmere, having a sheer depth of considerably more than 10,000 feet), and is liable to floods, which come with terrible swiftness, rise very high, and cause tremendous damage. The Indus enters the Punjab 812 miles from its source. Near Attock (q.v.), 48 miles lower down, it receives the Kabul River from Afghanistan, and then becomes navigable. Here it is only 2000 feet above sea-level. 150 miles below Attock it receives, on the left, the accumulated waters of the Punjab through the single channel of the Panjnad. Each of the five water-courses, as well as the Kabul, is practicable for inland craft to the mountains. Below its confluence with the Panjnad the Indus, instead of increasing in volume, becomes gradually less. Its basin is narrow, and the affluents are insignificant, while there is a great loss by evaporation. The river also divides into numerous channels, many of which become lost in the sand, while others return much shrunken in volume. The delta of the river covers an area of about 3000 sq. m., and extends for some 125 miles along the Arabian Sea. The main channel is constantly shifting. The delta is not on the whole very fertile, and is almost entirely destitute of trees. In both Punjab and Sindh the bed of the river is littered with islands and sandbanks. The cultivation of the arid plains

through which the lower Indus passes is dependent upon the annual overflow of the river and artificial irrigation fed by that overflow. The total length of the river is estimated at somewhat more than 1800 miles, and the area of its drainage basin at 372,700 sq. m. The Indus abounds with fish of excellent quality, and is infested by crocodiles. Before the opening of the Indus Valley Railway in 1878 the river was necessarily the principal means for the transmission of commerce; but since that event the railway has very greatly superseded navigation.

Industrial Schools. This term is used very variously, sometimes being synonymous with Ragged Schools, in which mechanical arts are taught; sometimes designating ordinary elementary schools, in which agricultural or some other industrial art is taught to the boys during one portion of the school-day, or in which sewing, cooking, washing, and ironing are taught to the girls. See EDUCATION, TECHNICAL EDUCATION, RAGGED SCHOOLS.

Inebriates. **RETREATS FOR.** The Habitual Drunkards Act, 1879, amended and made permanent by the Inebriates Act, 1888, made provision for the licensing of institutions for the reception and treatment of habitual drunkards. By these acts an inebriate might sign a bond before two justices of the peace for a period not exceeding twelve months, under which the licensee of the retreat had power to detain and control him during the time specified. No provision was made for the committal of any one against his will, nor for the establishment of retreats for the reception of persons unable to pay for their maintenance. The Inebriates Act of 1898, which came into force on 1st January 1899, gives power to courts of justice to commit persons convicted of penal offences whose offence may be traced to drink, or who may be found to be habitual drunkards, to three years' detention in a state (or certified) inebriate reformatory. The Secretary of State is empowered to establish state inebriate reformatories, or, on application from county or borough councils or private persons, to certify private inebriate reformatories. Full provision is made for the conducting and management of these institutions. The act applies to the whole United Kingdom. An amending act (1899) provides for the payment of expenses of prosecutions under the act.

In America there were in 1895 above fifty such hospitals, with over 1000 patients. In some states of the Union, inebriates may be compulsorily committed to these institutions. It is claimed that 'in fully 3000 cases, 35 per cent. of those who had remained under treatment at least one year had been permanently restored.'

Inertia (Lat., 'inactivity'), a universal property of matter, fully described in Newton's first law of motion, which asserts that *every body perseveres in its state of rest or of uniform motion in a straight line except in so far as it is compelled by force to alter that state*. Part of this principle was known to the ancients, and by them attributed to a certain repugnance to motion, which was a characteristic of all matter; but it was shown by Galileo that just as the body at rest could not of itself begin to move, so the body in motion could not of itself come to rest.—The *Moment of Inertia* is the sum of the products of every particle of a mass into the corresponding distance from a given point or axis of rotation.

Ines de Castro. See CASTRO.

Infallibility, the immunity from error, in all that regards faith and morals, which is claimed by the Roman Catholic Church, and, at least as regards the past, by the Greek Church, as represented in the decrees of the

councils which that church looks upon as œumenical. The latter claim, however, which does not go beyond that of *inerrancy*, or actual exemption from error up to the present time, differs widely from that of infallibility, as put forward by the Roman Church, which involves not alone an actual historical immunity from error, but also such a positive and aiding assistance of the Spirit of God as will at all times both protect against the possibility of error and guide and direct in the faithful teaching of all necessary truth. The infallibility claimed by the Roman Church is thus of two kinds, *passive* and *active*—the first (Matt. xvi. 18), in virtue of which the church never can receive or embrace any erroneous doctrine, no matter by whom proposed; the second, in virtue of which she is charged with the function (Matt. xxviii. 19; Mark, xvi. 15; Ephes. iv. 11-16) of permanently *teaching* to the world the essential truths of God, of actively resisting every access of error, and of authoritatively deciding every controversy by which the oneness of belief among the faithful may be endangered. Catholics regard this gift as a natural and necessary accompaniment of the authority in matters of faith with which they believe the church to be invested, and which, if not guided in its exercise by such infallible assistance, would be but a false light and an attractive but dangerous instrument of delusion.

Such is the notion of infallibility as claimed by the Roman Church. Two very important and practical questions, however, arise regarding it, both of which have been the occasion of much controversy even among Catholics themselves: (1) as to the *subject*—the seat or the organ of this infallibility, and (2) as to the *object*—the matters to which it extends.

As to the first, all Catholics have been agreed that the body of bishops, morally speaking, throughout the church, acting in common with the pope, constitute the most perfect organ of the infallibility of the church; and hence, that when they unite in any way, whether assembled in a general council or separated in place, their judgment is infallible. Thus, if a doctrinal decree was addressed officially by the pope to the whole church, and either expressly confirmed or tacitly accepted by the bishops, this decree was held to be infallible. In like manner, if a doctrinal decree, emanating even from a local council, as that of a national, or even a provincial church, was universally accepted by the pope and the bishops, that decree also was held to be infallible. In a word, wherever there is found the *united* judgment of the pope and the bishops, all have agreed in accepting it as the infallible judgment of the church. But should the pope alone judge without the bishops, then arose the well-known dispute of the Gallican and Ultramontane divines; the latter affirming, the former denying, the papal judgment to be infallible; but all agreeing that it was not binding *as an article of Catholic faith* so long as it had not received the assent of the body of the bishops. By the decree of the Vatican Council (1870) this controversy was decided after much dissension; the constitution *Pastor Æternus* teaches 'that when the Roman Pontiff speaks *ex cathedra*—that is, when he, using his office as pastor and doctor of all Christians, in virtue of his apostolic office defines a doctrine of faith and morals to be held by the whole church—he by the divine assistance, promised to him in the blessed Peter, possesses that infallibility with which the Divine Redeemer was pleased to invest his church in the definition of doctrine on faith or morals, and that therefore such definitions of the Roman Pontiff are irreformable in their own nature and not because of the consent of the church.' See PORE.

On the matters or subjects to which the gift of infallibility extends Catholics are agreed in one principle, that it embraces all those subjects, and those only, which are necessary for the maintenance of divine truth in the church. Hence, presupposing divine revelation, either written or oral, it embraces all questions of faith and morality, all subjects of general discipline, so far at least as to preclude the introduction, by authority of the church, of any discipline which should be injurious to faith or to morality. On the other hand, it does not embrace questions of science, or matters of fact, or abstract opinions unconnected with religion. On this point all Catholics have been agreed. But a very celebrated dispute arose in the 17th century, on occasion of the *Augustinus* of Jansenius, as to the infallibility of the church in judging of books, out of which originated the well-known Jansenist distinction of *law* and of *fact* (see JANSENISM). On this subject it will be enough to say that all Catholics are now agreed in recognising as a necessary condition to the effective infallibility that it should extend to the judgments upon books so far as to decide whether the doctrine contained therein may or may not be opposed to sound faith or morality.

[The Vatican Council produced a large literature, including Cecconi, *Storia del Concilio Vaticano* (1873); Frond, *Actes et Histoire du Concile Œcumenique de Rome* (8 vols. 1870-73). Salmon's *Infallibility of the Church* (1889) discusses the doctrine controversially from the Protestant point of view.] See also BASEL (COUNCIL OF), POPE, ROMAN CATHOLIC CHURCH, &c., and Rev. D. Lyons, *Christianity and Infallibility—Both or Neither* (1892).

Infamy, in law, was a stigma attaching to the character of a person so as to disqualify him from being a witness. It was distinguished into infamy of fact and infamy of law. Infamy of fact results from a depraved course of life and abandoned character, of law from the sentence of a court finding the person guilty of any crime to which the character of infamy attached. Since 1843 it has not been possible to exclude a witness on the ground of infamy, though questions as to character and as to crimes committed by a witness may be asked with a view of affecting his credibility.

Infant, in English law, is a term which includes all persons under the age of twenty-one. Such persons are subject to special rules of law, which may be summarised as follows:

(1) *Crime*.—A child under seven cannot be convicted of crime; a child between seven and fourteen can be convicted if it is shown that he knew the nature of his act. A boy under fourteen is presumed incapable of rape.

(2) *Marriage*.—Boys under fourteen and girls under twelve cannot contract marriage. As a general rule, infants of marriageable age require the consent of parents or guardians to marry; but the absence of such consent does not affect the validity of a marriage actually solemnised. A person procuring the marriage of an infant by fraud forfeits any property which accrues to him or her from the marriage.

(3) *Property and Contract*.—An infant may acquire and dispose of property, enter into contracts, and carry on business; but he is privileged to repudiate liability for his acts, except in certain cases. Contracts for necessaries (i.e. for things suitable to the infant's position in life) are binding on him; and settlements, &c., executed with the approval of a judge, in terms of certain acts of parliament, are also binding. On coming of age an infant may confirm or rescind any act by which he has acquired or disposed of property during infancy; if he continues to hold property acquired, he must perform obligations connected with it; if e.g. he has acquired shares in a company, he must

pay calls on them. If he has entered into a continuing contract (e.g. a contract of partnership), he is taken to have confirmed it, unless he rescinds and ceases to take the benefit of it within a reasonable time. As for his other contracts, he might formerly have confirmed them by an *express* ratification; he is now precluded from doing so by the Infants' Relief Act of 1874, which enacts that no action shall be brought on the ratification of a promise made during infancy. No will made by a person under twenty-one is valid. An infant may bring an action by his *prochein ami* or next friend (usually his father, if living). If an action is brought against him, a guardian *ad litem* may be appointed. A parent or guardian is not liable for the debts of an infant, unless he has expressly or by implication contracted to pay them. An infant may contract as agent for a person of full age; in this case his acts are regarded as the acts of his principal.

In Scotland the law differs in many respects from the law of England on this subject. The term infant is not used at all in a technical sense. All persons, if male, are in legal strictness called pupils till fourteen, and if female, till twelve; and from fourteen or twelve to twenty-one they are technically called *minors*. In general, the contracts of a pupil are absolutely void, and he is under the care of tutors, who are either his parents or others appointed by the court. A minor, on the other hand, may enter into contracts; but if they are to his lesion or prejudice he can reduce or set them aside any time within four years after majority. Moreover, if a minor go into trade, his contracts bind him, as they do other persons. Further, a minor can make a will or testament, operating on his movable estate, though he cannot alienate his heritable estate in like manner. The four years which are allowed to him after majority to consider whether he will set aside contracts are called *quadrimum abile*; and if he can prove lesion he is in that period entitled to restitution. In Scotland, also, a minor may marry as freely as if he were a major, and, indeed, he is in general his own master, or *sui juris*, at the age of fourteen (a female at twelve). See the article AGE.

Infant, FEEDING OF. When the health and strength of the mother admit of it, there is no doubt that the food provided by nature is far the best suited for infant nourishment. In this case the child should be fed entirely on breast milk for the first six or eight months at least, and partially for the remainder of the first year of life. Beyond this period, nursing is usually injurious to mother and child, but is often continued because of the idea that it tends to prevent pregnancy. If from any cause the mother is unable to nurse her infant, a wet-nurse is the best substitute; though the improvement effected in the preparation of artificial foods has rendered this method of bringing up infants less common than it used to be. The selection of a suitable nurse should be entrusted to the medical adviser, and is a responsible and difficult duty. When neither of these methods is available, the milk of some animal has to be used. Goats' milk and asses' milk have both been recommended, as more nearly resembling human milk than cows' milk does; but, as they are almost always difficult to procure, while cows' milk is abundant and cheap, it is this which in the vast majority of cases must be employed. The differences between human milk and cows' milk must therefore be recognised and allowed for. They may be summed up as follows: Cows' milk contains much less sugar, rather less fat, and considerably more albuminoids than human milk; and under the action of acids a much larger proportion of albuminoids coagulate, and form a much firmer

clot in the former than in the latter. To assimilate cows' milk as closely as possible to the natural food of the infant, it must be modified in some such way as the following: One tablespoonful of milk to be mixed with half a tablespoonful of cream, two tablespoonfuls of water (boiled), and a quarter of a teaspoonful of milk sugar for each meal during the first month. If the cows' milk still forms too firm a clot, a tablespoonful of lime water, or of barley water, may be substituted for one tablespoonful of plain water; or a little solution of gelatine, or of one of the prepared foods for infants, such as Mellin's, may be added. The quantity of milk, &c. must be gradually increased as the child grows, till at the sixth month it has nine tablespoonfuls of milk, one of cream, two of water, and a teaspoonful of milk sugar at each meal. It is sometimes, but not generally, necessary to secure a supply of milk from one cow. If ordinary milk disagrees, predigestion (by Fenger's liquor pancreaticus or Fainchild's peptonising powder) may overcome the difficulty. If milk cannot be borne in any form, some substitute (prepared 'infants' food, chicken broth, raw meat juice, &c.) must be used. But in all such difficult cases, medical advice should be sought.

There is no more fruitful source of illness in infants brought up on the bottle than imperfect attention to cleanliness, which leads to souring of the milk and severe indigestion. There should always be at least two bottles, tubes, &c. in use; and after a meal the apparatus should at once be taken to pieces, thoroughly cleansed with soda and water, and left steeping in fresh boiled water till it is required. No cork, wood, or other absorbent substance should be used in the construction of the fittings of the bottle, as this renders perfect cleanliness almost impossible.

Till after the sixth month at least the infant is unable to digest starchy foods, unless specially prepared as in the 'infants' food'; and the giving of rusks, biscuit-crumbs, &c. before this period cannot be too strongly condemned.

It is no less important to the infant than to the adult, but rather more, that the meals should be taken regularly. During the first six weeks, whatever method of feeding is adopted, a meal should be given on the average every two hours from 5 A.M. to 11 P.M. From this period to the eighth month the interval should gradually be increased to three or four hours, and always as far as possible the time of the meals should be the same from day to day. Of course these are merely general statements; the contentedness and thriving of the infant are the true guides in each individual case. To give it a meal every time it cries merely overloads the stomach and provokes disorder of the digestion.

After the eighth month five meals a day should be enough, and two should consist of farinaceous food, well cooked (rusks, stale bread crumbs, oat, barley, or wheat flour), as well as milk. About the tenth month the yolk of an egg may be given once or twice a day, or chicken soup in its stead. After the first year the range of the diet may be gradually increased, bread, mashed potato, meat broth, fish, chicken, well-boiled vegetables being gradually added. But many children thrive well on milk and farinaceous food alone up to two or three years of age, and if so may be allowed to continue on that diet.

Infante (from the Lat. *infans*, 'an infant'), the title given in Spain and Portugal to the princes of the royal family, the corresponding title of INFANTA being given to the princesses. Since 1388, however, the heir-apparent to the throne in Spain has been styled the Prince of Asturias, and the heir-apparent in Portugal, until the separation of Brazil from the mother country, bore the title

of Prince of Brazil. The personal domain of an Infante or Infanta is called the *Infantado*.

Infanticide, or the murdering of infants, was common in ancient times, and still prevails in some barbarous communities. The practice existed in Greece and Rome, and even found defenders in Plato and Aristotle. The latter in his *Politics* said the law should forbid the murturing of the maimed, and, where a check to population is required, abortion should be produced before the quickening of the infant. In Sparta, as in other Greek states, the law directed that when a child was born the father should carry it to an appointed place, there to be inspected by the elders of the community. If it was a promising child, they returned it to its parents to be educated; otherwise it was thrown into a cavern at the foot of Mount Taygetus. In ancient Rome the Twelve Tables directed malformed infants to be immediately destroyed, and by the *Patria Potestas* the father had an absolute power over his children extending to life and death; but the rigour of the paternal law both as regards the killing and the sale of infants was softened by subsequent legislation, and especially by Numa. Among the Norse the child's life hung in the balance till the father handed it to the nurse to be reared. If it was weak or malformed, or if the father disapproved of its living, the child was killed by exposure to the weather and to wild beasts. According to Cæsar the Gauls were invested with the power of life and death over their children, and so late as the 13th century the Poles killed imperfect children. Amongst the Arabs it required an ordinance to prevent the crime of killing children lest the parent should be reduced to want, and this element of anxiety for the father's independence and comfort entered largely into the calculations of many states, barbarous and civilised, with regard to their posterity. The Arabs also buried female infants alive.

In modern times infanticide prevails only amongst barbarous or semi-civilised nations, and even amongst these the increased intercourse with civilised states is gradually stamping out the practice. Until comparatively recent times child-murder prevailed throughout the whole of the South Sea Islands. In the Fijian island of Vanna Levu, or some parts of it, the infanticide reached, till the middle of the 19th century, a half and in others two-thirds of the child population. Amongst the Hindus the practice of destroying children, especially females, prevailed to a fearful extent, until it was checked under the Marquis of Wellesley's rule (1798-1805). The practice was forbidden by the Vedas; but, in consequence of the expense and the disgrace attached to girls remaining unmarried, the practice prevailed amongst the Rajputs—who destroyed all females except the first-born—and the native races. The methods of killing were poisoning by pills of tobacco, drowning in milk, smearing the mother's breasts with opium, and plastering the mouth with cow-dung. Notwithstanding the Koran, the Moham medans were inclined to the practice, but effected their object by means of abortion. Efforts began to be made towards the close of the 18th century, amongst others by Jonathan Duncan and Major Walker, for the suppression of the practice, and in 1853 these efforts were at last crowned with success at a dinner arranged for by Lord Lawrence. It was thought expedient to continue a system of surveillance by the police in some districts, and to institute a system of average numbers in families, which concentrated their vigilance upon those families which reached the lowest average. Amongst the Japanese the father had, but has not now, absolute power of life and death over his children. In China infanticide was, and in the

remoter parts of that vast country still is, common. One of the causes here is the right possessed by Chinamen of periodically repudiating their wives. Sometimes the infants were stilled by the midwives at birth, and sometimes they were cast into a neighbouring stream, where in some cases they were humanely kept afloat by a gourd, so that they might be saved from destruction by any compassionate person who might feel disposed. In early missionary times it was a part of the duty of missionaries to pick up and rear, or entrust to others for the purpose of rearing, the waifs who had been abandoned through the avarice, poverty, or callousness of their parents.

In nearly all the cases mentioned infanticide was prompted by religious or economic reasons, or indulged in from caprice or indolence; and it was permitted in deference to the power with which in primitive communities as well as in advanced states like Greece and Rome the father was endowed. Modern civilisation deals very differently with the subject. In all European states, although they differ widely in their treatment of infanticide and cognate crimes, human life is from its first to its last hour held sacred, and whoever puts an end to it is a murderer. Almost the only motive which in such countries now leads to infanticide is that of shame—the parents incurring the risk of committing child-murder to escape social disgrace. The efforts therefore of legislators and criminal lawyers on the one hand have been directed to the repression of abortion, concealment of pregnancy, and murdering the new-born infant, and of philanthropists on the other to remove temptation to commit the graver crimes by providing Foundling Hospitals (q.v.), where the offspring of sin may find a refuge. See also ILLEGITIMACY.

In England and Scotland the inexcusable killing of infants is theoretically murder, and the only excuse for killing the foetus is the safety of the mother; otherwise, Abortion (q.v.) is a criminal offence. The concealment of birth is also a criminal offence; see BIRTH (CONCEALMENT OF). The destruction of children may be effected negatively by not supplying food and clothing, as well as by the positive act of wounding or ill-treating; and if a parent or other person who is bound by law to supply food and clothing to the child refuses or neglects to do so, thereby causing its death, such refusal or neglect amounts either to murder or manslaughter, according to the circumstances. Moreover, the unlawful abandoning or exposure of any child under the age of two years, whereby the life and health of the child are endangered, is a misdemeanour punishable with three years' penal servitude. Where a person is charged with the murder of a very young child it is essential to prove that the child was in life. Under a statute of James I. there were presumptions against the mother, but in 1803 the trials for offences of this class were placed under ordinary rules of evidence. The presumption which now obtains that every new-born child found dead was born dead is believed by certain jurists to have encouraged infanticide. The test of a child being born alive is not that it breathed, or had an independent circulation after it was separated from the mother; it is enough that the child was fully born. Hence, if a man strike a woman with child, so as to cause the death of the child, he is neither guilty of murder nor of manslaughter of the child. In all cases of the murder of infants the question whether the child was fully born, and so the subject of murder, is generally one of medical jurisprudence. In England and Wales the annual number of verdicts of murder of infants one year old and under varied in 1879-88 from 65 to 103. The above offences in reference to infanticide are

punished in a similar manner in Scotland, where, though the killing of a completely born infant is murder, a verdict of culpable homicide is frequently returned. Concealment of pregnancy is the usual charge under 49 Geo. III. chap. 17.

It has been stated that every day an impost is held upon the bodies of children destroyed through the design, the neglect, the ignorance, or the mental infirmity of the mothers. Even when the act may fairly be regarded as a crime, its enormity is generally greatly lessened in the eye of the law by the consideration of the physical condition and moral disturbance of the parent.

An Act of 1872 obliges those who undertake for hire to nurse infants under the age of one year, for a longer period than twenty-four hours, to have their house registered, and to keep records of the children they take charge of. They must also give notice to the coroner or procurator-fiscal of such infants' deaths, and are under obligation to keep sanitary houses. By an important statute passed in 1889 any person over sixteen who wilfully ill-treats, neglects, abandons, or exposes a boy under fourteen or girl under sixteen years of age, or causes or procures this to be done, in a manner likely to cause the child unnecessary suffering or injury to its health, is guilty of a misdemeanour, and is liable to £100 of fine or imprisonment for two years, or to both. Lesser penalties are inflicted on summary conviction. The fine may be increased where the offender is proved to be interested in the death of the child. See CHILDREN (CRUELTY TO), and BURIAL SOCIETIES.

Infantry. See ARMY.

Infant Schools. The subject has been already treated under Education (q.v.). But there still remain a few points to be adverted to. Pastor Oberlin (q.v.) may be regarded as the founder of infant schools. He appointed women in his own parish to assemble the little children between the ages of two and six, to interest them by conversation, pictures, and maps, and to teach them to read and to sew. The first infant school attempted in Great Britain was in connection with Robert Owen's socialistic establishment in Scotland. The education and training of young children were matters of great interest and study to Pestalozzi (q.v.). His system was adapted to English requirements by the Home and Colonial Infant School Society, founded in 1836. This society has done excellent work in training teachers and instituting model infant and juvenile schools. But the most successful system of educating quite young children is the Kindergarten (q.v.).

Infection. The grounds for believing that each of the large class of communicable diseases depends upon the presence within the body of a distinct living organism have already been stated (see GERM). The manner in which each of these supposed organisms behaves in originating fresh cases of disease is, however, almost as characteristic as the effects it produces on the body.

(1) In malarial or miasmatic diseases, chief among which is ague, though they present many analogies to truly infectious diseases, there is no evidence that the malarial can be transmitted from the sick to the healthy. The disease poison is derived from soil, water, or air, in which it seems to live and multiply.

(2) Intermediate between these and the more characteristic infectious diseases is a group of which cholera and typhoid (enteric) fever may be taken as types. Here the infectious material has its origin chiefly from the defects of the patient, but seems to acquire infectious properties only after it has been some time (probably for several days) outside the human body.

(3) The largest and most typical class includes typhus, smallpox, measles, scarlet fever, whooping cough, and many others. In all these the disease is directly and immediately communicable from the sick to the healthy. But there are striking differences in the conditions under which infection usually takes place. The poison of typhus, the dreaded 'jail fever' of past times, is rapidly destroyed by admixture with air, and the danger of its spreading can be much diminished by free ventilation. In smallpox the infection can retain its vitality for years on the walls of a room, or in the artificially dried discharge from the pustules; in scarlet fever it may exist for many months in articles of clothing. Measles is not least infectious in the early stage, when it presents merely the symptoms of a bad cold; scarlet fever infection is not at its worst till the rash has faded and the skin begins to be shed.

(4) The last group consists of those diseases in which the poison does not diffuse itself through the air, but requires to be directly inoculated to produce the disease—e.g. syphilis and hydrophobia.

This classification of diseases believed to be dependent upon organisms, though practically convenient, cannot be considered a strictly accurate one; for many of the diseases in group 3, perhaps all, can be propagated by inoculation, and the infection of some may be able to develop outside the body and behave like those in group 2. Enough has been said to show the complexity of the problems, both practical and scientific, presented by the subject. As to the Infectious Diseases Notification Act of 1889, and other cognate matters, see HYGIENE, DISINFECTANTS, CONTAGION, and the articles on the several diseases.

Infefment, or **SASINE**, a Scotch law term, used to denote the symbolical giving possession of land, which was the completion of the title, the mere conveyance not being enough. The instrument of sasine was the notarial instrument embodying the fact of infefment. The old ceremony, which was not abolished until 1845, was thus performed. The baillie of the superior of the lands, the attorney of the vassal, a notary, and two witnesses proceeded to the lands in which sasine was to be granted. The attorney delivered to the baillie the superior's precept of sasine, and required him to perform his duties. The baillie delivered the warrant and relative deeds to the notary, who read and published them to all present. The baillie thereupon delivered the symbols of possession, sometimes a pen, to the attorney, and the attorney then took instruments in the hands of the notary by giving him a piece of money. But now the necessity of a separate formality is unnecessary, it being sufficient to register a conveyance in the register of sasines in Scotland. In Scotland an *infefment in security* is a temporary infefment to secure payment of some debt; and an *infefment of relief* is a similar security to relieve a cautioner.

Inferral Machines, contrivances made to resemble ordinary harmless objects, but charged with some dangerous explosive. An innocent-looking box or similar receptacle is partly filled with dynamite or other explosive, the rest of the space being occupied by some mechanical arrangement, mostly clockwork, which moves mandibly, and is generally so contrived that, when it has run down at the end of a predetermined number of hours or days, it shall cause the explosive substance to explode. For a statement of the uses to which this class of inferral machines has been put by the anarchist parties, see DYNAMITE. Fire-ships (q.v.) were employed in former times; and modern nations apply a similar principle in their torpedo boats (see TORPEDOES). Bombs or hand grenades,

in so far as they have been employed for the felonious destruction of human life, must also be accounted infernal machines. The most notorious instances have been the unsuccessful attempt on Napoleon III. by Orsini (q.v.) in 1858 and the killing of Alexander II. of Russia in 1881. See also CHICAGO, ANARCHISTS.

Infidel, amongst Christians, popularly means one who rejects Christianity as a divine revelation, but is not used of heathens (though they are *infideles*, Lat. 'unfaithful') or heretics. By Moslems Christians are called by a corresponding term ('*giaour*,' '*kafir*,' &c.). See ATHEISM, DEISM, APOLOGETICS, CHRISTIANITY, HERESY, PERSECUTION.

Infinite. In philosophy, infinite is that which is without any limitation, and, like absolute and unconditional, is used especially of the Infinite, of God. As to our knowledge of the infinite, some (as Hamilton and Mansel) hold that the idea is purely negative; Descartes affirmed that the idea of the infinite was not merely the idea of an objective reality, but is implied as a necessary condition of every other. See ABSOLUTE, CONDITION, RELATIVITY OF KNOWLEDGE; Hamilton's *Discussions*, Mansel's *Limits*, Calderwood's *Philosophy of the Infinite*, Spencer's *First Principles*.

In mathematics, the term infinity and the phrases infinitely great and infinitely small are of constant occurrence; and the symbol ∞ is usually said to denote a magnitude infinitely great, the symbol 0 a magnitude infinitely small. Are these magnitudes infinitely great and infinitely small to be reasoned about in the same way as ordinary finite magnitudes? Are these symbols ∞ and 0 to be treated in the same way as ordinary algebraic symbols, a , b , x , y , &c.? With respect to the symbol 0 there seems at first sight to be little difficulty, for we are accustomed to regard it as denoting the absence of all quantity, or as the result obtained by subtracting any finite quantity from a quantity equal to it. It is found convenient however, though it would be impossible to explain in short compass the grounds of the convenience, to give another meaning to the symbol 0. The new meaning will perhaps be understood from the following illustration. Take the algebraical expression $\frac{1}{x}$, and suppose x capable of increasing so that it may become greater than any assignable quantity; then the value of $\frac{1}{x}$ will diminish and become less than any assignable quantity, and the limit towards which it tends, that is to say, the value from which it may be made to differ as little as we please, is symbolised by 0. The same expression will enable us to give a meaning to the symbol ∞ . Suppose x capable of diminishing so that it may become less than any assignable quantity; then the value of $\frac{1}{x}$ will increase and become greater than any assignable quantity, and the limit towards which it tends, that is to say, the value from which it may be made to differ as little as we please, is symbolised by ∞ . The symbols 0 and ∞ therefore, denoting the limits towards which certain variable quantities tend when particular suppositions are made, cannot be used absolutely like the symbols denoting finite quantities; because $a \div a = 1$, it would be erroneous to conclude that $0 \div 0 = 1$ or $\infty \div \infty = 1$. Expressions such as $0 \cdot 0$, $\infty \div \infty$, $\infty \cdot \infty$, $0 \cdot \infty$, and some others are called indeterminate forms; for methods of evaluating them, see Chrystal's *Algebra*, chap. xxv., or De Morgan's *Differential and Integral Calculus*, chap. x.

Infinitesimals is the name applied to the method adopted by Leibnitz as the foundation of his Differ-

ential Calculus. Leibnitz considered magnitudes as composed of infinitely small elements or infinitesimals. Those elements which are infinitely small compared to any finite magnitude are infinitesimals of the first degree; those which are infinitely small compared to infinitesimals of the first degree are infinitesimals of the second degree; and so on. The principle of the method briefly stated is that two finite magnitudes are equal if they differ only by an infinitely small magnitude. Though the results obtained by the application of infinitesimals are seen to be always in accord with the results obtained by other methods, and a method which always leads to correct conclusions must be logically sound, yet the fundamental principle does not at first sight seem rigorously exact, and the method looks as if it were merely one of approximation. In consequence it has now come to be usual to found the calculus on the doctrine of limits.

Infinitesimal Calculus. See CALCULUS.

Infirmaries. See HOSPITAL.

Inflammation is the most important of all the morbid processes that fall under the notice of the physician or surgeon. The most obvious symptoms or phenomena of inflammation, when it attacks an external or visible part, are pain, redness, heat, and swelling. If a healthy man gets a splinter of wood or any other foreign body imbedded in any fleshy part he begins to experience pain at the part, and this is soon succeeded by redness of the skin. In its early stages the process is known as irritation; but soon, if the foreign body be not removed, the pain and redness increase, and are accompanied by a firm and extremely tender swelling at and around the spot, and a sense of abnormal heat. These purely local symptoms are succeeded, if the inflammation reach a certain degree of intensity, by a general derangement of the vascular and nervous systems, to which various names, such as constitutional disturbance, symptomatic or inflammatory fever, &c., have been applied.

Numerous observers have attempted to trace the exact phenomena of inflammation, by microscopic examination of the transparent parts of animals in which the process has been artificially excited. From observation made on the web of the frog's foot and other transparent parts of animals by Wharton Jones, Paget, Cohnheim, Burdon Sanderson, Ziegler, and many others, the main features of the process are now well known.

In inflammation of moderate severity the blood-vessels of the part are seen to dilate, and the current of blood through them, at first sometimes a little accelerated, becomes much slower than the normal. In consequence of this retardation the white blood-corpuscles, being somewhat sticky in consistence, fall out of the central stream, and drag along the sides of the vessel, where, as the inflammation increases, they are arrested. Then follows the most remarkable part of the process. Minute buds are seen to form on the outside of the walls of the veins and capillaries, each one corresponding to a white blood-corpuscle in the interior. These buds grow larger at the expense of the corpuscles, which thus pass through the wall of the vessel without any break in its continuity; and the migration continues till the tissue around the vessels is crowded with corpuscles. At the same time an abnormal quantity of fluid exudes through the walls of the blood-vessels, and in part coagulates, forming with the corpuscles what is known as coagulable or plastic lymph. From the capillaries red as well as white blood-corpuscles pass into the tissues. If the inflammation be more intense complete arrest of the flow of blood in the vessels (stasis) takes place.

We may now consider the explanation of the cardinal symptoms of inflammation. The *redness*

depends upon there being more blood than usual in the blood vessels of the affected part; sometimes also upon the occurrence of hemorrhage in the inflamed tissue. The *swelling* depends in part upon the distension of the blood-vessels, but mainly upon the effusion of fluids and blood-corpuscles above described. These are termed the *products* of inflammation; and many changes, some of a reparative nature and others of an injurious tendency, depend upon their presence. The *pain* may vary from mere discomfort to intense agony. It is probably due to compression of the sensory nerves of the affected part by the dilated vessels, and the exudation. It is often throbbing. There is usually most pain in those parts in which the tension produced by the swelling is the greatest, as in bone, serous and fibrous membranes, &c. The pain occurring in inflammation is always aggravated by pressure, and by this means the physician can often distinguish between inflammatory and non-inflammatory disorders. The *heat* is seldom so much increased as the sensations of the patient would lead him to believe; it does not rise above the maximum heat of the blood in the interior of the body. This increase of heat depends upon the increased flow of arterial (or highly oxidised) blood to the part.

The blood obtained by bleeding a patient suffering from inflammation of any important organ usually presents a peculiar appearance after coagulation known as the *buffy coat* (see BLOOD). Another and a more important change in the blood in inflammation is the augmentation of the fibrin, which often rises to two, three, or more times its normal quantity.

The further course of inflammation is much more variable. The most favourable termination is *resolution*, where the products of the inflammation are gradually removed by the lymphatics, and the tissue returns to its normal state. If the exuded blood-corpuscles accumulate in large amount (*suppuration*) they form an Abscess (q.v.), and must in general be evacuated before cure can take place. If the inflamed tissue be superficial its outer layers may die and be thrown off (*ulceration*), leaving a sore which heals by Cicatrization (q.v.). If the inflammation be severe and extensive Gangrene (q.v.) or *necrotification* may ensue.

In the return to health of inflamed tissues, where neither resolution nor death of the patient has taken place, formation of new tissue is necessary to fill up the gap which is left by suppuration or ulceration. This is effected mainly by the action of the exuded leucocytes present in the 'plastic lymph,' which under suitable conditions becomes gradually organised into fibrous tissue, bone, &c.; but the restoration of the epithelial covering, where a breach in the surface either of skin or mucous membrane has occurred, is effected only under the influence of epithelial cells present at the edge of the gap. The process is essentially similar to the healthy repair of broken bones (see FRACTURE), or incised wounds, though many authorities do not apply the term inflammation to these cases. It is thus that parts recently severed from the body may be some times replaced and still live. The success of the Taliæotian operation, by which a new nose is grafted in the position of that which had been lost, of the operation of injecting a stimulating fluid into cystic tumours, with the view of setting up adhesive inflammation, and of various other surgical operations, essentially depends upon the property of organisation possessed by inflammatory exudation, or closely allied products. Although the organisation of plastic lymph is thus essentially a conservative and reparative process, it leads in many cases to untoward results. Thus, when a serous membrane (e.g. pleura, pericardium, peri-

tonium) is inflamed, the exudation between its contiguous surfaces often becomes transformed by the same process into fibrous tissue, forming layers or bands which seriously interfere with the functions of the organs involved (lung, heart, intestine, as the case may be) after the inflammation has subsided. In inflammation of the iris the pupil may be rendered irregular or immovable, or may even be closed up by inflammatory exudation. In endocarditis, or inflammation of the lining membrane of the heart, exudation may be deposited in wart-like masses on the valves, and may thus occasion some of the worst forms of cardiac disease.

The causes of inflammation are very various. Among predisposing causes must be reckoned any condition which lowers the vitality of the whole body, or of any particular part of it. The most obvious exciting causes are mechanical violence, chemical irritants, excessive heat or cold, producing injury of a part of the body which leads directly to inflammation in that part. Less obvious, but not less certain, is the effect of exposure to cold in exciting inflammation of internal organs. But of all the causes the most important undoubtedly, though they have only been recognised within the last three decades of the 19th century, are micro-organisms—bacteria, &c. (see GERM). Besides the numerous *specific* diseases attended by inflammation of various organs and tissues proved or believed to be due to these bodies, many forms of what is known as *simple* inflammation—e.g. acute abscess—have been shown to be associated with them. Some authorities go so far as to say that no true inflammation can take place without them; and though this opinion has not been proved, it is certain that almost all the most severe forms of inflammation are characterised by the presence of some form of micro-organism.

The inflammatory diseases of the most important organs are described under their specific names, and, as a general rule, the termination *itis* is employed to indicate an inflammation. Thus, peritonitis signifies inflammation of the peritoneum; iritis, inflammation of the iris; &c. Inflammation of the lungs, however, is usually known as pneumonia instead of pneumonitis, and of the pleura as pleurisy instead of pleuritis. See PNEUMONIA, PLEURISY, ENTERITIS (for inflammation of the bowels), PERITONITIS, STOMACH (for gastritis), LIVER (for hepatitis), EYE (for iritis), BRAIN, &c.

It is unnecessary to enter into the consideration of the treatment of inflammation further than to remark (1) that if possible we must remove its exciting cause, which can seldom be done except when the inflammation is external; and (2) that the patient should be placed on a strictly anti-phlogistic regimen (which implies a total abstinence from solid animal food and stimulating drinks, due attention to ventilation, temperature, &c.). Of the direct remedies, one of the most powerful, both for good and evil, is blood-letting, although at present it is rarely used. The medicines chiefly employed are purgatives, preparations of mercury, tartar emetic, and opium; while, as external applications, hot fomentations or poultices (sometimes applications of cold water or ice are preferable), and counter-irritation by means of blisters, sinapisms, setons, &c., are often of service.

Inflection. See GRAMMAR.

Inflorescence. This term is applied by botanists in a concrete and special, as well as in an abstract and general sense—i.e. first to any single group or natural aggregate of flowers arising upon a common main axis, and secondly to the various modes or principles of floral arrangement themselves. Despite that endless superficial diversity upon which the characteristic aspect of different

species and larger groups so much depends, these apparently indefinite variations may readily be reduced to a small number of easily intelligible types. For, while the earlier botanists naturally tended to develop a nomenclature corresponding to the multiplicity of outward forms which inflorescences acquire, the progress of research has simplified this by centering attention upon the few and simple modes of branching by which they arise. We naturally set out with any plant of which the axis continues to grow indefinitely, but of which a number of secondary axes arising in the axils of the leaves are developed as flowers. When the pedicels of these flowers tend to reach a moderately equal length the inflorescence is known as a *raceme* (fig. 1, *a*); or when the process of floral development arrests them, so that the flowers are practically sessile, we have a *spike* (fig. 1, *d*). The growing point of most racemes and spikes, however, tends to be checked by the reproductive stress, and the axis thus frequently ends, or rather seems to end, in a terminal flower. Good examples of this essentially racemose or spikeate type are furnished by many Liliaceae, Scrophulariaceae, &c. —

Fig. 1.

a, raceme of lily of the valley (*Convallaria*); *b*, corymb of candy-tuft (*Iberis*); *c*, umbel of fruits of fennel (*Foeniculum*); *d*, spike of vervain (*Verbena*); *e*, head of fruits of dandelion (*Taraxacum*); *f*, *Dorstenia*; *g*, *fig* (*Ficus*) in vertical section.

e.g. *Tritoma*, foxglove, mullein, &c. Even such a curious inflorescence as that of the pine-apple may now easily be interpreted as a greatly condensed spike of fruits, crowned by its leafy growing point.

The shortening of the main axis of a raceme may take place after ordinary development has begun, so that the upper internodes are much less developed than their predecessors. The pedicels of the younger flowers naturally share the same arrest of development, and thus it is that the comparatively long pedicels of the lower flowers place them on much the same level as the higher ones, and even as the summit of the axis. This variety is known as the *corymb* (fig. 1, *b*), so familiar in the candy-tuft. When all the internodes are so shortened that the pedicels arise from practically the same level, we have the *umbel* (fig. 1, *c*), so characteristic of the Umbelliferae.

Suppose this vegetative arrestment and floral precocity to be continued still further, internodes and pedicels alike become arrested, and the result is a crowded cone or excessively shortened spike of sessile flowers. By continuing the same process which gave us the corymb, the cone necessarily tends to appear more and more depressed through the more rapid upgrowth of its lower portions; thus we have that characteristically expanded axis, so compactly set with florets as to resemble at first sight a single flower, familiarly

known as the head or capitulum of the Composites (fig. 1, *e*). The spiral arrangement of the florets so obvious in a sunflower is simply that of the depressed cone, which we may again draw out in imagination into the corymb, the spike, or the raceme, with which it is in principle identical.

A capitulum fundamentally similar may, however, be evolved in a slightly different way, by the more or less complete arrestment of the secondary axes of an umbel. Hence it is that a few umbelliferous plants, like *Astrantia*, or still better the sea-holly (*Eryngium*), &c., come to present that appearance which so often induces the beginner to confuse them with Composites.

But, since it is manifest that the same embryonic shortening may occur in any type of inflorescence whatsoever, it becomes evident that we must reserve the term capitulum for the type of inflorescence presented by the Composite or Scabious, leaving the various superficially resemblant forms or *pseudo-capitula*, as of sea-holly already referred to, or those of sea-pink, of bergamot, &c., to be separately analysed according to their true origin.

Returning, then, to the capitulum proper, we must continue to keep clearly in view that conception of vegetative growth (as reaching its maximum rate only at some distance behind the growing point) which may be actually verified by measurements of any growing shoot or root. The conical axis thus not only tends to broaden and flatten, but its lower portion must at length overtake the apex, and a perfectly flat receptacle, as in some species of *Dorstenia*, results. The margins next outgrow the apex, and the cone is now becoming a shallow saucer (other species of *Dorstenia*, fig. 1, *f*). The saucer next becomes a cup, or even flask; and the remarkable hollow inflorescence of the fig (fig. 1, *g*) is thus seen to be morphologically akin to the capitulum, and through this by the corymb even to the original raceme itself.

The study of vegetative branching (see BRANCH) has, however, shown us that we may have to do with compound or sympodial axes as well as simple or monopodial ones. That is to say, in our primary axis the growing point may perish, leaving, however, of course, all the more opportunity for the development of the secondary axes latent in its lateral buds. This disappearance of the primary growing point, having once set in, soon works back, until we have it occurring immediately after the development of the first lateral bud. This then readily takes its place for practical purposes, just as a larch or pine which has lost its top renews it by the upgrowth of a branch. But the new axis dies in turn after giving birth to its successor, and so on; thus the *falsæ axis* or *sympodium* is formed. Inflorescences of this type are known as *cyms*. The simplest in principle is that of the Day-lily (q.v.). It is commonly known as the *helicoid cyme* (fig. 2, *h*), since the origin of the new axes winds on in the same spiral order as that of the leaves upon the primary axis itself. The distinction from a raceme is, however, easily made when we notice that the so-called bracts are not really bracts at all, but are more or less opposite to the flowers; being really only the axillant leaves of the next axis, which bears its flower only after producing a leaf with the bud of its successor.

But in other cases the spiral may change its direction with each new axis, and the false axis thus assumes a very different appearance, that of the *scorpioid cyme* (fig. 2, *i*), of which the classical example is furnished by the Boraginaceae (Goebel, however, regards these as unilateral racemes, and offers *Tradescantia*, *Echeveria*, &c. as more real types). The reversal of the spiral has been prettily verified by noting how in the scorpioid cyme of the

Rock-rose (*Helianthemum*) the spiral of the calyx runs in an opposite direction in each successive lower.

So far we have been dealing with cymose inflorescences as arising in plants with alternate leaves: in opposite leaved plants (e.g. Caryophyllaceae and Begonia (q.v.)) the resultant form is necessarily very different. Let the growing point terminate in a flower as before; but since each of the two leaves immediately below is in an equally favourable condition, both as regards radiation and aliment, we have two secondary axes instead of one. Hence, instead of one secondary axis continuing in the line of the primary one, we have necessarily two of equal strength and divergent at an equal angle. The main axis thus at first sight

Fig. 2.

Diagrammatic representation of *b*, helioid cyme; *a*, scorpioid cyme; *c*, dichloasium.

seems to have forked, especially when the terminal flower disappears, just as in the false dichotomy so apparent in the branches of the lilac or mistletoe; and hence the old name of *dichotomous cyme*, which, however, it is evidently necessary to correct, as *dichloasium* (fig. 2, *b*), *biparous cyme*, or the like.

This inflorescence may undergo shortening, or in more physiological language remain more or less embryonic, as in most Labiate (which, however, present all gradations, from the fully-developed cymes of *Hyssopus*, through the 'false whorls' or 'verticillasters' of the majority of genera, to the terminal pseudo-capitulum of *Bergamot*). The apparent umbel of geraniums and the pseudo-capitulum of the sea-pink have also this origin.

Not only modifications of these leading types, but various combinations, simple, compound, and complex, and in all degrees of reduction or exuberance, may also arise; the question of separating all the preceding types of inflorescence as *radial* from a small residuum as *basal-central* also presents itself. See Goebel's *Outlines of Classifications* and Van Tieghem's *Traité de Botanique*.

Influenza (Ital., 'influence'; called in French *le grippe*), one of the class of diseases to which the term zymotic has been applied, has been long recognised by medical writers. The popular application of the name to any severe cold in the head is not sanctioned by medical authority. Cullen called it *catarrhus cataractae*, but although, in most cases, it closely resembles ordinary catarrh, it presents certain points of difference from that disease. In addition to the ordinary symptoms of catarrh, there is a sudden, early, and very striking debility and depression of spirits. This early debility is one of the most marked and characteristic signs of influenza. The mucous membranes (especially those of the respiratory organs) are much affected. The tongue is white and creamy, the sense of taste is lost, there is no appetite, the

pulse is soft and weak, the skin, although at first hot and dry, soon becomes moist, and the patient complains of pains and soreness in various parts of the body.

In simple, uncomplicated cases convalescence supervenes in the course of a week or sooner; but influenza is very frequently conjoined with bronchitis or pneumonia, in which case it is much more persistent and dangerous. There is, moreover, an extreme proneness to relapse on the slightest exposure, even after the patient feels perfectly recovered.

Influenza affords an excellent example of an epidemic disease, a whole community being often attacked in the course of a few hours. From this it may be inferred that the occurrence of this disease is connected with some particular condition of the atmosphere, but what that condition is is not known. Not infrequently influenza follows close upon a sudden thaw; sometimes it is preceded by thick, ill-smelling fogs; but hot and cold, wet and dry weather have all been attended by severe outbreaks of the disease. Like cholera, influenza generally, but by no means constantly, follows a westerly direction, or one from the south-east towards the north-west, and its course seems to be altogether independent of the surface currents of air, as it often travels against the prevailing wind.

The epidemic which prevailed during the winter of 1889-90 in most parts of the civilised world, the first of importance in Britain for nearly forty years, presented some points of difference from most of the previously recorded outbreaks. In particular, there was in many places a much larger proportion of cases without any catarrhal symptoms whatever than appears to have been observed before. Such cases present a close resemblance to Dengue (q.v.), and many observers have come to the conclusion that there is a much closer relation between the two diseases than has been hitherto supposed; while some believe that the epidemic in question was itself dengue modified by climate, and not influenza at all.

The most important point in the treatment of influenza is *not* to bleed the patient, or in any way to depress his vital powers. He should be kept in bed; his bowels should be gently opened, his skin slightly acted upon, if dry; and, if the cough be troublesome, a mustard-poultice should be applied to the chest, and an expectorant mixture prescribed. Antipyxin and antifebrin were during the epidemics of 1889-95 found very valuable in combating the feverishness and pain of the early stage. In persons of weak or broken-down constitutions, ammonia, beef-tea, and wine and water must be given from the outset. The debility that often remains for a considerable period after the establishment of convalescence is best met by the preparations of iron, quinine, and strychnia.

Few diseases increase the death-rate to such an extent as influenza; more, however, in consequence of the great number of persons who are attacked in a severe epidemic than in consequence of its danger in individual cases. See EPIDEMIC, GERM.

In Forma Pauperis (in the character of a poor person). Persons are said to sue *in forma pauperis* when the law allows them to conduct lawsuits without paying fees to court-officers, counsel, or solicitors. In England a statute of Henry VII. affirming the common law, provided that such as would swear themselves not worth £5, except their wearing apparel and the matter in question in the cause, should be exempt when plaintiffs, but not when defendants, from the payment of court fees, and should be entitled to have counsel and attorney assigned to them by the court without fee. They were further exempted from costs when unsuccessful; a privilege which, according to Blackstone, amounted

in former times only to the rather uncomfortable alternative of choosing between paying and being whipped. This indulgence, first confined to plaintiffs, was afterwards extended to defendants. It was at first restricted to the Common Law Courts, but afterwards adopted in the practice of the Equity and Probate and Divorce Courts. No one can sue *in forma pauperis* unless the opinion of counsel on his case, and an affidavit by the party or his solicitor that the same case contains a full statement of the material facts, be produced to the court applied to. A suitor *in forma pauperis* is not entitled to costs unless by order of the court. In Scotland an Act of 1424 established the poor's roll to secure a like privilege to poor persons there.

Information. See CRIMINAL LAW.

Informers. In English law, the person who sues for a penalty under some statute. In many statutes which define offences—not criminal, but savouring of criminality—encouragement is often given to persons who are willing to sue on behalf of the crown, the pecuniary penalty or part of it being given to the informer. This kind of action is called a *qui tam* action, from the use of the words *qui tam pro domini regniū quam pro seipso*, &c. In criminal proceedings an accomplice who turns king's evidence, if accepted as a witness by the crown, is called an approver or prover. Ever since the days of the professional 'sycophant' at Athens the informer has been regarded as an odious character. In Ireland, owing to the unsatisfactory relations between the government and the people, almost any person who gives evidence against a prisoner runs the risk of making himself unpopular. In Chancery proceedings at the suit of the attorney-general the informer is called a relator. In Scotland an informer is the party who sets the Lord Advocate in motion in criminal prosecutions, and the Lord Advocate is bound to give up the name of the informer, who is liable in case of malicious prosecutions. See APPROVER, SPY.

Infusions are aqueous solutions of vegetable substances obtained without the aid of boiling. In this respect only do they differ from decoctions, in the manufacture of which boiling is resorted to. Infusions are prepared by digesting the vegetable substance (root, bark, &c.) in hot or cold water in a covered earthenware vessel. Cold water is preferable when the active principle is very volatile, or when it is desired to avoid the solution of some ingredient in the vegetable which is soluble in hot, but not in cold water. For example, in preparing the infusion of calumba cold water is preferable, because it takes up the bitter principle (which is the essential ingredient), and leaves the starch-matter undissolved. In most cases, however, boiling water is employed. Infusions are preferred to decoctions when the active principle volatilises at a boiling heat, as in the case of essential oils; or when ebullition readily induces some chemical change, as in the case of senna.

Infusions may also be prepared by Percolation (q.v.), a process which is extensively employed in the preparation of tinctures. When thus prepared they are less liable to decay than when prepared on the old system.

The fresh infusion, while possessing a finer flavour, is in danger of being superseded in pharmaceutical practice by the concentrated infusion. On account of the trouble and expense involved in making small quantities of the fresh preparations, recourse is frequently had to the concentrated ones, which, when diluted with seven times their bulk of distilled water, more or less represent the fresh article. Where the active principle is a volatile one it is very difficult to retain the full aroma in the concentrated state, and to

this question much pharmaceutical attention has been turned. The concentrated infusions contain from 20 to 25 per cent. of alcohol, which is essential for their preservation. The simple infusions may be preserved for a short time by the addition of a trace of chloroform.

Infusoria, a name given to several classes of active Protozoa, some of which appear in great numbers in stagnant *infusions* of animal or vegetable matter. The great majority are provided with vibratile locomotor processes of their living matter, usually in the form of cilia or flagella; and, though these may be retracted when the animal occasionally encysts itself, they are practically permanent, and express the predominantly active constitution of these cells. Most are microscopic, but many are readily seen when foul water is held in a glass vessel between the eye and the light. Yet there may be more Infusorians in a cup of stagnant water than there are people on the globe. Infusorians occur both in fresh and salt water, and a few are parasitic; they feed on vegetable or on animal matter, on bacteria or on one another, while some possessed of a green pigment, closely allied to, if not identical with chlorophyll, probably absorb carbonic dioxide after the manner of plants. Most Infusorians possess a 'mouth'—i.e. a special aperture through which the food-particles are wafted in by the cilia or flagella. As single cells, comparable to the units of ciliated epithelium in multicellular animals, to the active spores of plants, and to male cells or spermatozoa, they exhibit the usual protoplasmic structure and the central differentiation or nucleus. There is usually a definite rind, often with cuticular structures; and there are generally contractile vacuoles, probably excretory in function. Many Infusorians occur not as single individuals, but as members of a colony, the results of multiplication remaining clubbed together, and often forming masses easily visible to the unaided eye. They multiply with great rapidity by dividing into two, or by rapid successive division into a larger number (spore-formation); and thus a single Infusorian, with favourable temperature and nutrition, may in four days become the ancestor of a progeny of a million, in six days of a billion, in seven and a half days of a hundred billions—weighing one hundred kilogrammes! If the life of the species, however, is to be sustained, conjugation or incipiently sexual union of two Infusorians (not of the same family) must occur, for if the descendants of one individual be left by themselves the whole family falls victim to 'senile degeneration,' and the members dwindle away. In many cases among ciliated Infusorians the researches of Maupas and others have shown that the conjugation of two forms means an interchange of nuclear elements; in other cases the two individuals fuse into one. When the two conjugates are of unequal size, as in the common *Vorticella* or bell animalcule, it seems justifiable to call the smaller male and the larger female.

The classes included under the title of Infusorians are as follows, beginning with those ciliated forms to which zoologists often restrict the term.

Ciliata.—Infusorians characterised by the predominance of alternately bent and straightened motile processes known as cilia. The usual nucleus is accompanied by a second neighbour nucleus (para- or micro-nucleus), the elements of which are interchanged in conjugation. They are classified according to the relative position and size of their cilia. The slipper-animalcule (*Paramecium*), and *Opalina* parasitic in the intestine of the frog illustrate those which are more or less completely ciliated (*Holotricha*); the beautifully coloured species of *Stentor*, the genus *Balantidium*, with one species parasitic in man, and the common *Bursaria*

are among those with heterogeneous cilia dissimilar in size and form (Heterotricha); the stalked bell-animalcule Vorticella and its beautiful allies Epistylis and Carchesium, the jumping Halteria, with a girdle of springy, bristle-like processes, and Opalidium, which multiplies into large hollow colonies, sometimes 5 inches across, have a special wreath of cilia round the mouth (Peritricha); and lastly, those with cilia restricted to the under surface are well illustrated by Euplotes, Oxytricha, and Stylonielia.

Flagellata.—Infusorians with a vibratile or undulatory flagellum, or with more than one, used for locomotor or food-catching purposes, including a vast number of forms, some of which are often called Monads, while others—e.g. Volvox—approach if they do not unite with the Algae. One of the very commonest flagellate genera is Englena. To the flagellates proper there have to be added the Choanoflagellata, with a single flagellum surrounded by a beautiful wine-glass like collar—e.g. Salpingoeca, and the interesting Proterospongia—a colony with slight division of labour among its members and like a little fragment of sponge flesh; also the Dinoflagellata, with two flagella, one parallel, the other transverse to the long axis of the body—e.g. Peridinium, an extremely common marine form, affording food to some fishes; lastly, the Rhynchoflagellata, with a large locomotor flagellum, including two genera—the phosphorescent marine ‘night-light’ (Noctiflumen), and Leptodiscus, a beautiful bell-like form, which seems within the compass of a single cell like a far-off prophesy of medusoid architecture.

Suctoría or Suctorialia.—Infusorians with cilia only in their free-living youth, usually fixed as adults, and always with prehensile or suctorial processes like tentacles, by means of which they prey upon other Protozoa. Acineta and Podophrya are suctorial; the common Acineta is only prehensile.

In beauty of form and movement, in the liveliness of their behaviour, and in the intricate phases of their life-history, Infusorians afford almost inexhaustible material for investigation, which many workers have shown to be at once captivating in itself and full of biological suggestiveness. In the general economy of nature Infusoria are especially important as a food-supply to small animals, and in so far as they unite with Bacteria in working decaying matter once more into the cycle of life, or in reducing it to simpler elements.

See BACTERIA, MONAD, PARAMOECIUM, PROTOZOA, VORTICELLA; Claparede and Lachmann, *Études sur les Infusoires* (Geneva, 1858-61); Stein, *Organismus der Infusorien-Theorie* (Leip. 1859-83); Saville Kent, *Manual of the Infusoria* (Lond. 1880-82); Ray Lankester, article ‘Protozoa,’ *Encycl. Brit.* (1885); Maupas, *Archiv. Zool. Expér.* (vi. 1888); Batschli, ‘Protozoa,’ in Bronn’s *Thierreich*.

Infusorial Earth. DIATOM EARTH, KIESELGÜHR, a siliceous deposit formed chiefly of the frustules of Diatoms (q.v.). It is used as *Tripoli Powder* for polishing purposes, and as an absorbent of nitro-glycerine in making Dynamite (q.v.).

Ingelheim. LOWER and UPPER, two small German towns, 10 miles E. of Bingen. The former (pop. 3000) claims to be the birthplace of Charlemagne, and has ruins of the magnificent palace he built here; the latter (pop. 3300) was once a free city of some importance.

Ingelow. JEAN, a popular poetess and novelist, was born at Boston, Lincolnshire, in 1820. Her first efforts in verse were published anonymously in 1850 under the title of *A Rhyming Chronicle of Incidents and Feelings*. These gave indication of considerable power, as well as of the influence of Tennyson and Mrs Browning, to whose writings she appears to have been strongly drawn in youth.

A good deal of Miss Ingelow’s poetry is of a devotional or religious cast, introspective in quality and melodious in style. But she has also written some powerful ballads, and of her minor pieces *The High-tide on the Coast of Lincolnshire, 1551*, is probably both the finest and the best known. Of her larger poems *A Story of Doom* (1867) has been the most successful. To about the same time belong *Deborah’s Book and the Lonely Rock, Grandmother’s Shoe, The Suspicious Jorklaw, The Life of John Smith, The Minnows with Silver Tails, Studies for Stories*. Among her novels may be mentioned *Off the Skellogs, Fated to be Free* (1875), *Don John* (1876), and *Sarah de Berenger* (1880). An edition of poems appeared in 1880-87 (3 vols.) She died 20th July 1897.

Ingemann. BERNHARD SEVERIN, Danish poet and novelist, was born, May 28, 1789, at Thorkildstrup, in Falster. He first wrote lyrics (*Proem, &c.*), and then collections of *Fairy-tales and Stories*. But his best works were a series of historical novels, in which he took Walter Scott for his model—*Valdemar Seier* (1826), *Erik Menved’s Childhood* (1828), *King Eric* (1833), and *Prince Otto of Denmark* (1835). The poems *Valdemar the Great and his Men* (1824), *Queen Margaret* (1836), and *Holger Danske* (1837), which are based, like his novels, on incidents of Danish national history and tradition, rank among Ingemann’s most successful efforts. Besides being prolific he was also versatile, and essayed his hand in nearly all branches of pure literature, not the least estimable of his productions being *Psalms* (1825). From 1822 he taught Danish language and literature in the Royal Academy of Sorø, near Copenhagen. His collective works were published in 39 vols. (1843-64). He died 24th February 1862.

Ingermanland. the old Swedish name for which is now the government of St Petersburg.

Ingersoll. JARED, an American jurist, born in Connecticut in 1749, studied at Yale and in London and Paris, and became a prominent lawyer in Philadelphia. He was a member of congress in 1780-81, was in 1787 a delegate to the convention that framed the Federal constitution, and in 1812 was the Federalist candidate for the vice-presidency of the United States. He was a judge in the district court of Philadelphia at the time of his death, 31st October 1822.—His son, CHARLES JARED, born in Philadelphia, 3d October 1782, sat in congress in 1813-15, and there advocated the principle that ‘free ships make free goods;’ was for fourteen years United States district attorney for Pennsylvania; and was a prominent leader of the Democrats in congress from 1841 to 1847. He died 14th May 1862. He was the author of some poems and a drama, a political satire entitled *Washington’s Letters* (1810), and an *Historical Sketch of the War of 1812* (4 vols. 1845-52).

Ingersoll. ROBERT GREEN, was born at Dresden, New York, 11th August 1833, the son of a Congregational minister of very broad views. With his brother he opened a law office at Shawneetown, Illinois, but removed in 1857 to Peoria. In 1862-65 he was colonel of a Federal cavalry regiment; in 1866 he was appointed state attorney general. He was a successful lawyer, a well-known Republican campaign orator, and attracted more notice than he deserved by his lectures directed against the Christian religion, and by many pamphlets and books published with the same object. He died 21st July 1899.

Ingleby. CLEMENT MANSFIELD, an eminent Shakespearean scholar, was born at Edgbaston, Birmingham, 29th October 1823, was educated privately, and afterwards proceeded to Trinity College, Cambridge, where he graduated B.A. in

1847, and became M.A. in 1850, and LL.D. in 1859. He entered his father's office as a solicitor, and practised for a short time, though by no means assiduously; or *con amore*; and after his father's death in 1859 relinquished the profession altogether to devote himself to a busy life of letters. He was one of the two English honorary members of the Weimar Shakespeare Society, an original trustee of Shakespeare's birthplace, a vice-president of the New Shakespeare Society (a post he afterwards resigned), and successively foreign correspondent and vice-president of the Royal Society of Literature. He died 26th September 1886.

His earliest work, *Outlines of Theoretical Logic* (1856), was followed by *An Introduction to Metaphysics* (1864-69) and *The Revival of Philosophy at Cambridge* (1870). But the most important work of his literary life began when he published *The Shakespeare Fabrications* (1859) and *A Complete View of the Shakespeare Controversy* (1861). These were followed by *Was Thomas Lodge an Actor?* (1868); *The Still Lion* (1874), enlarged into *Shakespeare's Heresies* (1875); *The Centurie of Praise* (1874); *Shakespeare: the Man and the Book* (1877-81); *Shakespeare's Bonus* (1883); *Shakespeare and the Enclosure of Common Fields at Wilton* (1885); and an edition of *Cymbeline* (1886). A selection of admirable *Essays* on a wide range of subjects was issued in 1888 by his son, Holcombe Ingleby, who prepared in the same year, for private circulation, a brief memoir of his father, with a collection of his epigrams, translations, and verses.

Ingoldsby, THOMAS. See BARHAM.

Ingolstadt (called *Auracant* and *Chrysopolis*, i.e. 'the golden city'), a town and first-class fortress of Bavaria, on the left bank of the Danube, 53 miles by rail N. of Munich. It contains two castles of the former dukes of Bavaria-Ingolstadt (now used for military purposes); the Gothic church of Our Lady (1425), in which is the tomb of Eck, Luther's opponent; and the former Jesuit college. Brewing, cannon-founding, and the manufacture of gunpowder and salt are the only industries. Pop. (1875) 14,474; (1885) 16,390, mostly Roman Catholics. A university was founded here in 1472, which reckoned Renclin and other eminent scholars among its professors, and a century after its foundation had 4000 students. It was removed to Landsbut in 1800, and to Munich twenty-six years later. Ingolstadt was the first German town at which the Jesuits were permitted to establish themselves, and to teach publicly from the university chairs. Loyola gave it the fond title of 'his little Benjamin.' Here, too, Adam Weishaupt established the Illuminati (q.v.). Ingolstadt, which existed in the 9th century, was first fortified in 1539. In 1827 the fortifications, which had been destroyed by the French in 1800, were restored upon a first-class scale. See works by Gerstner (1853) and Kleemann (1883).

Ingraham, JOSEPH HOLT, author of *The Prince of the House of David*, was born at Portland, Maine, in 1809, was for some time a sailor, and afterwards taught languages at a college in Mississippi. He published a string of wild romances, such as *Captain Kyd* and *Lafitte, or the Private of the Gulf*; but after he was ordained to the Episcopal ministry, in 1855, he chose biblical subjects for his stories, and wrote *The Prince of the House of David* (1855), *The Pillar of Fire* (1859), and *The Throne of David* (1860). He died in 1860.

Ingres, JEAN DOMINIQUE AUGUSTE, French painter, was born at Montauban, 15th September 1781. He became a pupil of David in 1796, and five years later gained the 'Grand Prix.' In 1806 he proceeded to Rome, where he resided for four teen years. He then spent four years in Florence, where he painted 'The Yow of Louis XIII.,' a picture which, on being exhibited at the Paris

Academy in 1824, broke down the indifference of the public to the work of David. In Italy he had adhered to the style of David, but had modified it by the inspiration he got from Raphael and other old masters. To this period belong his best portraits, and his 'Edipus and the Sphinx,' 'Venus Anadyomene,' 'Romulus and Aeron,' 'Virgil reading the *Æneid*,' 'Raphael and Fornarina,' 'Roger and Angelique.' Returning to Paris in 1826, Ingres was appointed professor of Fine Arts at the Academy, and became the recognised head of a great school. But the acrimonious criticism passed upon his 'Apotheosis of Homer' (1827) and 'Martyrdom of St Symphorian' (1834) made him gladly embrace the opportunity of succeeding Horace Vernet as director of the French Academy in Rome in 1834. There he painted 'Stratonice' and the 'Portrait of Cherubini.' The exhibition of these and other pictures in Paris at length turned the tide of popular admiration full and strong in his favour. He relied more upon form and line than upon colour; some of his best productions ('Girl after Bathing,' 'Edipus and the Sphinx,' the 'Odalisque,' and the 'Fontaine'), compositions of a few figures each, are unquestionably deserving of admiration; but of late it is commonly held that for a time he was unduly overrated. At the exhibition of 1855 he was awarded the grand medal of honour for his collection of pictures, and was nominated a grand officer of the Legion of Honour. He returned to Paris in 1841, and died there on 14th January 1867. See Lives by Delaborde (1870), Blanc (1870), and Schmarsow (1884; in Dohme's *Kunst und Künstler*).

Ingrossing. See ENGRASSING.

Ingulph, abbot of Crowland, long considered the author of the *Historia Monasterii Croylandensis*, according to Ordericus Vitalis, was secretary to Duke William of Normandy, and was by him in 1086 made abbot of Crowland, where he died, 16th November 1109. The *Historia Monasterii Croylandensis* was printed by Sir Henry Savile in his *Scriptores Rerum Anglicarum post Bedam* (1596), and in a more complete edition, with the continuation by Peter of Blois, in vol. i. of the *Rerum Anglicarum scriptores ceteros* (Oxford, 1684). There is a translation by H. T. Riley in Bohm's *Antiquarian Library* (1854). Some writers even of the 18th century questioned the entire genuineness of the book; but their scepticism did not proceed further than the hypothesis of interpolations by a later writer. But in 1826, in the *Quarterly Review*, Sir Francis Palgrave endeavoured to prove that the whole so-called History was little better than a novel, and was probably the composition of a monk in the 13th or 14th century. This has been conclusively proved, as the student will find, by Mr Riley in the *Archæological Journal* (vols. i. and ii.), and by Sir T. D. Hardy in the *Descriptive Catalogue* (vol. ii.).

Inhambane, a Portuguese station, capital of a district on the east coast of Africa, lies just south of the tropic of Capricorn, and is beautifully situated on its bay, but unhealthy. The town dates from 1764, and has 6500 inhabitants, of whom some 70 only are Europeans.

Inheritance. See HER. INTESTATE, WILL, SUCCESSION, HEREDITY.

Inia (*Inia geoffrensis*), a toothed fresh-water Cetacean, not unlike a dolphin, but with certain anatomical peculiarities which keep it outside that family. It is found in some of the upper tributaries of the Amazons, and in the lakes near the Cordilleras. It measures about 8 feet in length, has a long cylindrical snout with stiff hairs, and a very

slight dorsal fin. It feeds chiefly on fish, and is hunted for the sake of the oil which it yields. It

Inia.

is generally found in little troops of three or four. The females show great affection for their young.

Initials. Though in general it is usual and regular in all legal deeds and writings for a party to write his ordinary signature in full, yet in many cases, especially in documents of a mercantile nature, signature by initials will bind equally with the full signature. If, however, the subscription to a bill of exchange be by initials or marks it will not warrant summary execution; and the pursuer of an action on the bill will have to prove that such initials or marks are the party's usual mode of subscribing.

Injections. This term is applied in medicine to fluids thrown into the passages or cavities of the body by means of a syringe or elastic bag. The fluids thus injected into the *rectum* or lower bowel are termed *Clysters* (q.v.). Hypodermic Injections are treated under that head. See also TRANS-FUSION OF BLOOD.

Injector. Fig. 1 shows in section a simple form of injector for raising water. Steam issuing from the pipe S, into the vessel WR, will first create a partial vacuum above W by dragging air with it, and then, when the water-level is above the nozzle, will, on collapsing by condensation, impart its energy to the water and drive it up through the narrow neck below R, to a height of about one foot for every pound of steam-pressure per square inch. It is doubtful whether these injectors can work so economically, as regards expenditure of steam, as ordinary slow-moving pumps do; but they possess many conveniences and advantages which are bringing them into use.

Feed-pumps, for feeding water into steam-boilers, are difficult to keep in order when driven at high speed. The very rapid action of the valves severely tries their durability. In the case of locomotives inconvenience was often occasioned by the fact that their feed pumps acted only when they were running; and thus, if an engine happened to stand still for any length of time, the water occasionally got too low in the boiler. M. Henri Gillard's injector, now in general use in place of high-speed feed-pumps, acts equally well whether the engine is running or at rest.

The diagram fig. 2 will give an idea of the essential parts of Gillard's injector. A is the steam-boiler, B the water-level, CDE a pipe into which steam is admitted; this pipe terminates in a cone DF, which is enclosed in a larger cone III. In the cone DF the pointed plug E can be raised or

lowered so as to increase or diminish the area of the aperture at its lower end E. G is a pipe communicating with the water cistern, and admitting water into the external cone III. K is a pipe communicating with the boiler under the water-level. On opening communications between the boiler and this apparatus it might be expected that steam would rush out at F, and water at K, both currents meeting with great force, and escaping into the atmosphere between the two openings.

Paradoxical as it may appear, the water at K, although it is actually, by reason of the head of water arising from the difference of level between the aperture at K and the water-level at B, subject to a greater boiler-pressure than is the steam in the cone DF, is yet overpowered, and driven back into the boiler by the stream of water and condensed steam issuing from H; and thus water, from the pipe G and the

Fig. 2.

tender or cistern, is introduced into the boiler, and constitutes the feed-water. The energy of the collapsing steam at F is transferred to water in III; this is driven forward in a stream, which is at its narrowest at K; in this stream the actual energy per unit of bulk at K thus comes to exceed the potential energy of the boiler-water at K, and its actual velocity to exceed the possible velocity of outflow from K; whence the outflow from K is overpowered. In practice this injector is a somewhat expensive apparatus in consequence of the number of adjustable parts required. Variations in the pressure of steam require alterations in the area of the steam-passage, and in the distances between the mouths of the conical openings for the outflow and inflow of steam and water.

Injunction. in English law, is an introductory writ, by which a superior court stops or prevents some inequitable or illegal act being done. If the party disobeys the injunction he may be attached for contempt of court, and imprisoned till he obeys. In Scotland a remedy of a similar kind is called an Interdict (q.v.).

Ink is a general term for any fluid substance which, when applied to a suitable surface, leaves upon it a partially or wholly indelible impression. Any such fluid may be used for writing purposes; but, as the recording material is generally paper, this fluid must have either an affinity for the fibrous matter of which the paper is made, or for the sizing material used to produce upon it a homogeneous surface. This is necessary to prevent the removal of the ink by water; and this power of mounting itself is one of special importance, as upon it depend the permanency and indelibility of the records. Certain salts have this property, especially salts of iron, which when exposed to the air absorb oxygen, the result of which is that the pale blue

green solution produced by mixing proto-salts of iron with vegetable matters containing tannic or gallic acid is converted into a dense blue-black insoluble compound, which cannot be removed from the paper unless it is tampered with by means of chemicals capable of decomposing or destroying it. It is owing to the formation of this insoluble compound that writing-ink, when left in open vessels exposed to the air, becomes thick andropy, and unfit for use. Other black inks are prepared from salts of chromium and vanadium. These inks are in some cases more suitable than the simple writing-inks described above. Sulphate of indigo is also used as a colouring matter. A black ink which lays claim to indelibility is prepared from nigrosine, one of the aniline compounds; but the colour is much inferior to that of ordinary inks, and is not absorbed by the paper fibre to the same extent. Writing-inks are generally acid in character, which causes the corrosion on metal pens; but this property rather tends to enhance the value of the ink, as it retards the bleaching action noticeable in old documents. Creasote, or common wood vinegar, is added to most inks to prevent moulding.

The following will be found excellent recipes for the manufacture of black writing-ink on a small scale: *With galls and sulphate of iron*.—1 lb. bruised galls, 1 gal. boiling water, 5½ oz. of sulphate of iron (copperas) in solution, 3 oz. gum-arabic, previously dissolved, and a few drops of an antiseptic, such as carbolic acid. Macerate the galls for twenty-four hours, strain the infusion, and add the other ingredients. *With Logwood*.—Boil 10 oz. logwood in 20 oz. of water; boil again in 20 oz. more water, and mix the two decoctions; add 2 oz. chrome alum, and boil again for quarter of an hour; and 1 oz. gum-arabic. The product is 25 oz. deep black ink.

Copying-inks are prepared by adding sugar, gum, or glycerine to ordinary writing-inks. These substances protect the colouring matter (combined with the iron) from the oxidising influences of the air, by forming a skin or impervious varnish over the writing. Thus, when the damp 'tissue' is pressed upon the writing, sufficient unoxidised ink is transferred to stain the paper from back to front, and expose a legible copy on the upper side. Aniline colours dissolved in water holding gum or sugar in solution are also used as copying fluids. Owing to their intense colouring power these inks are useful where many copies from one document are required, but only for temporary use, as on exposure to air or light these colours quickly fade, and the record is lost. Copyable printing-ink is prepared from these materials; and, when written and printed matter is to be copied, as on way-bills or invoices, its use is a great convenience. Copyable pencils are prepared from the same materials (in a solid form). But there is a very serious objection to the use of such inks and pencils: the printed or written matter can be entirely removed by means of alcohol or other solvents.

Many attempts have been made to produce writing-inks which would hinder or render impossible tampering with documents, but without much success. The necessity for such inks seems exaggerated, as it has been found that even with the best manipulative skill and chemical knowledge it is practically impossible wholly to remove writing produced with the common iron and tannin ink, such as is almost universally used.

Coloured Inks. These are essentially solutions of colouring matters. Red ink is best prepared by dissolving pure carmine in ammonia; blue, by dissolving Prussian blue in oxalic acid; green, by dissolving one per cent. methyl green in warm water. Other colours can also be simply prepared, but not being in demand are not usually met with in

commerce. The desirable properties in all writing-inks are that they shall flow freely and not gum or clog the pen, that they shall remain perfectly fluid (without depositing the colouring matter), and that they shall be reasonably permanent in character.

Sympathetic Inks.—These are of great variety, and although possessing an interest to the lover of the marvellous, are not in common use. When weak solutions of cobalt are used (chloride or nitrate), the writing remains invisible until the paper is heated; it then assumes a red colour, which on being exposed to damp air (or breathed upon) changes to green. Salts of lead or bismuth, on being treated with sulphuretted hydrogen, give a black impression. When a weak solution of galls or tannic acid is used the paper on being plunged into a bath of a per-salt of iron will show the characters in black. This is a useful method of restoring faded old writing, and in cases where chemicals have been used with the purpose of removing it.

Printing-ink.—This is a greasy or oily compound in which solid pigments are held in suspension, and is altogether different both in appearance and composition from the writing-inks we have described. It also is usually applied to paper surfaces, and amongst other qualities it must possess the property known to printers as 'distribution'—i.e. of being easily spread out in a layer, the tenacity of which will not cause it to fill up the interstices of and between the types; it must also attach itself to the paper when the type is pressed upon it, detaching itself from the latter entirely; it must possess the apparently opposite properties of drying on the paper within reasonable time, whilst it shall not do so on the type, rollers, or ink-tables; and lastly, it should be permanent in so far as the impressions on paper should have no tendency to change. The various qualities of printing-ink may be described under three heads—viz.: (1) newspaper inks; (2) bookwork inks; and (3) lithographic inks. With the common and consequently cheap printing-inks it is not necessary that the more expensive drying oils be employed as a vehicle or varnish for the colouring matter. Common oils made from paraffin and resin are used, mixed with ordinary lampblack. From this compound, when applied to the surface of printing paper, the oily matter is absorbed, leaving the colouring matter as a stain on the outside, which does not 'set off' to such an extent as to prevent its employment for cheap periodicals and newspapers. The better class of printing-inks, however, must actually dry upon the surface of the paper in the same manner as paint will dry when applied to a wall. This result is obtained by the employment of drying oils—that is, oils which have the property of absorbing oxygen and becoming gum-like or resinous in character. Thus, when the ink, prepared from linseed, poppy, or walnut oil, is exposed to the atmosphere, especially if assisted by heat, the colouring matter becomes imprisoned or varnished over with a resinous coating, which prevents it setting off or staining any substance brought in contact with it. In preparing the varnish of such inks the oils already mentioned are heated to 500 or 600 F., at which temperature they are kept for a period varying with the degree of viscosity or thickness of the varnish required. In this operation the oil (a compound of fatty acids with glycerine) gradually thickens, without much loss of colour or weight, pungent fumes of acrolein, due to the decomposition of the glycerine, being given off. The varnish so produced is mixed with lampblack, prepared either from coal or burning oil, or from the imperfect combustion of gas, and after very careful grinding is in a condition for use.

The manufacture of coloured inks is practically

much the same as for black inks, only great care must be exercised to secure the purity of the varnish, and to see that the chemicals employed do not react upon one another. For example, when vermilion (which is a compound of sulphur and mercury) is employed with colours containing iron or lead, the splendid colour of the vermilion is entirely destroyed by the formation of black sulphur compounds with the iron and lead. It is impossible in such an article to give more than the general outline of this manufacture, with which are connected many mysterious processes for which there is no chemical explanation. The technical manuals are said to contain reliable recipes to guide to its manufacture, and we must refer our readers to those for details. The chief drawback in regard to coloured printing-inks is their tendency to fade on exposure to the air and light. This drawback has become more accentuated since the introduction of coal-tar colours, with which it seems to be the rule that the more brilliant and beautiful they are the less are they fit to resist these destructive influences.

In lithography both writing and printing inks are employed, these being of a peculiar character. The former consists of a soapy fluid holding in suspension fatty matters (shellac, white wax, and tallow), which on being transferred to the stone are absorbed and retained by its porosity. The subsequent application of lithographic printing-ink (which is only the finest variety of printing-ink prepared in an especial manner) to the damp surface of the stone causes it to collect and form a layer on the portions which the lithographic writing-ink has penetrated. As in the case of letterpress-inks, those for lithographic purposes are prepared in black and coloured varieties.

Special inks are prepared for colotype and tinplate printing. Stamping or obliterating inks may either be prepared by thinning down black or coloured letterpress printing-inks with linseed-oil or turpentine, or by grinding aniline colours with glycerine and treacle.

Indian Ink or China Ink.—This is a mechanical mixture of the purest and densest lampblack, with a solution of gum, gelatine, or of agar-agar. The black paste is dried and pressed so as to form cakes, in which condition it is sold. The lampblack is prepared by burning sesame or other oils, controlling the supply of air so that in place of a clear flame the carbon from the burning oil is deposited in fine flakes in the form of lampblack. For the very finest varieties the material used for this purpose is camphor. The lampblack or carbon so produced is amorphous, and of an intensely black colour. In this condition it is seldom used for the purpose of ordinary writing, but when rubbed down with water forms a material used by draughtsmen for plans, &c. Inks of a similar nature can be prepared by mixing the solutions already mentioned with colouring matter.

Marking-ink.—When certain salts of silver or platinum are applied to textile fabrics these materials are reduced in the fibres of the fabric, and the writing so produced is not removed by the ordinary scouring process to which such articles are subjected. Aniline in the presence of oxidised substances also produces a useful indelible ink.

Ink-stains.—The removal of writing ink stains from linen is easily effected, by alternately dipping the parts in a solution of oxalic acid and hypochlorite of lime (or soda). If the stains be old and have assumed the brown colour of iron mould, warm diluted muriatic acid will be found effectual in their removal. Where the fabric is coloured the removal of ink stains is more difficult, as the chemicals employed in the former case are inadmissible. In this case a solution of pyrophosphate of

soda may be used with advantage, as this salt does not seriously affect even delicate colours. It is of course necessary to thoroughly wash the fabric after the removal of the stains.

Inkermann, a village in the Crimea, situated near the eastern extremity of the harbour of Sebastopol. See CRIMEAN WAR.

Inland Revenue. See EXCISE, TAXATION.

Inlaying is the art of decorating flat surfaces by the insertion of materials differing from the ground or body in which they are inlaid, in colour, texture, or other qualities. The body or basis may be wood, stone, or metal, and the inlaid or encrusted substances may be woods of various colours, ivory, mother-of-pearl, tortoiseshell, precious and other metals, marbles, and hard and precious stones, all these substances being selected principally on account of the brilliancy and variety of their colours. Inlaying in wood is known generally as *marquetry*; in metals the inlay principally practised is called *Damascening* (q.v.); and in marble and precious stones it forms a variety of *Mosaic-work* (q.v.). As is the case with most decorative arts, the origin of inlaying can be traced to eastern countries. While some kinds of inlays were known in ancient Rome, the art as practised in modern times first took root in Venice in the 15th century, when small caskets were ornamented with inlays of ivory and wood in strictly geometrical patterns, such as continue to be reproduced to this day in the familiar inlay-work of Bombay. Contemporaneously the Florentines began to ornament furniture, &c. with small inlaid dice of ivory arranged to form various patterns, and this style of inlay has since become generally known as *Certosa-work*, from the fact that the choir-fittings in the church of the Certosa or great Carthusian monastery, near Milan, are ornamented in this manner. From these beginnings developed the *Tarsia-work* of Italy of a century later, which, dealing at first with geometrical patterns in wood, developed into inlaid representations of architecture, views, figures, and drapery, and finally into foliaceous scrolls of modern marquetry. Marquetry-work in furniture was greatly elaborated in France, Germany, and Holland towards the close of the 17th century, and workers in wood found great delight in skilful elaboration of intricate designs. Towards the close of the 17th century a new development of marquetry was effected by a French artist, Charles André Boulle, in the exclusive use of inlaid veneers of tortoiseshell and brass, now known as *Buhl-work*. Both in design and execution Boulle's work was of remarkable quality; the colour of his tortoiseshell was frequently heightened by a backing of gold or vermilion, and his brass-work was enriched with skilful engraving. Towards the close of the 18th century, while marquetry of a most elaborate character was being made in Germany and Italy, the richest triumphs of the art were produced in France by the famous *ébénistes* Reiser and Roentgen; but the Revolution put an end for the time to the manufacture.

Pietra-duca, which consists of an inlay of bright-coloured, hard, and precious stones, in slabs of marble or in panels of wood, is allied to the ancient mosaic-work which flourished in the palmy days of Rome; but true mosaic, although embedded, is not inlaid. *Pietra-duca* began to be made in Italy in the 15th century, but its extreme costliness prevented its extensive application. Two varieties were made in Italy, one being an inlay of minute pieces of stones with colours so arranged as to form a design or picture, like mosaics of larger size. This is known as *Roman mosaic*, in contradistinction to *Florentine mosaic*, which consists of slices of

stone shaped and inserted to form definite portions of the required design. This latter class of inlaid-work was introduced into India by a French artist, Austin de Bordeaux, who decorated the famous Taj Mahal at Agra in pietra dura of the richest and most elaborate character. The art then took root in that region, and to this day pietra-dura of manifestly European character in design continues to be a characteristic art industry of Agra.

The ornamental treatment of metals by inlaying is principally confined to the encrusting and inlaying of wire and fine plates of gold and silver into iron, steel, and bronze. The inlaying of gold and, to a minor degree, silver wire into iron or steel is known as Damascening (q.v.). In India such damascening is known as Kuit-work, and extensively practised in the North-western Provinces. Effective combinations of inferior metals are also made in India; silver inlaid in a black alloy of copper, lead, and tin being known as Bidri-work, from Bidar, in the Deccan. Combinations of copper and brass, and of brass and tin, are also common in the household vessels of the Hindus. The Japanese, who possess many alloys, excel in combining and inlaying them, often in relief, in their art metal manufactures.

Inn (ancient *Enns*), a river of Germany, the most important Alpine alluvial of the Danube, rises in the south of the Swiss canton of Grisons, and flows north-east through the valley of the Engadine, and onwards through Tyrol and Bavaria, to its junction with the Danube at Passau in a stream (320 yards) broader than that of the Danube. Its total course is 317 miles. In Bavaria its bed is broad and sown with islands.

Inn is the legal designation of a house or hotel where lodging and refreshment are provided for travellers generally. Public houses, &c. are not properly described as inns unless some rooms are set apart for guests to lodge in. An inn may be set up without a license; but if excisable liquors are sold the innkeeper must take out a license; and even temperance hotels are made subject to police inspection, to prevent evasion of the law.

An innkeeper is bound to open his house to travellers generally; he may not refuse refreshment or lodging to any person who is able and willing to pay, unless such person is drunk or disorderly, or tainted with infectious disease. He is, of course, bound only to give such accommodation as he has. If the traveller has a horse and luggage the innkeeper is bound to receive them if he has accommodation, provided the traveller himself intends to lodge there as a guest. But the traveller is not entitled to select whatever room he pleases, and if he will not accept such reasonable accommodation as is offered, the innkeeper may order him to leave the house. An innkeeper has a lien or right to detain the horse, carriage, or goods of his guest for that part of the reckoning applicable to each respectively, and this lien he acquires even if the horse, &c. be not the property of the guest. He has no right to detain the person of his guest.

By the Roman law an innkeeper was bound to restore goods entrusted to him by his guests, unless they were lost by some *damnum fatale*, or inevitable misfortune; this was the effect of a clause in the edict beginning *Navata, carponea, stabularia*. The same rule was adopted by the English common law. Hence, if a guest was robbed of his goods at an inn the innkeeper was liable, unless the guest had taken upon himself the care of his own property, or the loss was due to the default or negligence of the guest himself, his servant, or companion; and the landlord was not permitted to escape liability by putting up a notice that he

would not be answerable for losses. But the Innkeepers Act, 1863, provides that an innkeeper shall not be liable to make good the loss of any goods, &c. (not being a horse or carriage) to a greater amount than £30, unless the loss has been occasioned by his own wilful default, or the property has been deposited with him for safe custody. A copy of the first section of the act must be exhibited in the hall or entrance to the inn. The liability of innkeepers in respect of goods belonging to their guests extends to all keepers of public-houses, &c., but not to persons who let lodgings. The keeper of a boarding-house or lodging-house is free from liability if he exercises ordinary care—i.e. such care as he takes of his own goods. The Innkeepers Act of 1878 permits a landlord (after giving notice as required by the act) to sell the property of a guest who has left without paying. In Scotland the Roman rule of law as to innkeepers' liability has been adopted, and the law is substantially the same as in England, except that no indictment would lie against an innkeeper for refusing a guest. See further, as to the licenses required by innkeepers, the articles LICENSING LAWS and LIQUOR LAWS.

Inmate Ideas. See COMMON SENSE, DESCARTES.

Inner House, the name given in Scotland to the higher divisions of the Court of Session (q.v.).

Inverleithen, a police-borough (1869) of Peebles-shire, near the Tweed's left bank, 6 miles ESE. of Peebles, and 12 W. of Galashiels. Its first woollen-factory was established in 1790, about which time its saline spring (Scott's 'St Roman's Well') came into celebrity; but the great extension of its woollen industry dates from fifty years later. Pop. (1841) 463; (1891) 2512.

Inver Temple, one of the Inns of Court (q.v.).

Innes, Cosmo, lawyer, antiquary, and historian, was born at Duns, on Deeside, 9th September 1798. His father, formerly the laird of Leuchars, was a scion of the old family of Innes of Innes. Cosmo was educated at the Edinburgh High School, and he graduated both at Glasgow and Oxford. In 1822 he passed as a Scottish advocate, became sheriff of Moray in 1840, and subsequently was appointed clerk to the Second Division of the Court of Session. In 1846 he was elected to the (unpaid) chair of History in the university of Edinburgh. Cosmo Innes is perhaps best known as the author of *Scotland in the Middle Ages* (1860), and *Sketches of Early Scotch History* (1861), but he also prepared the first volume of *Acts of the Scottish Parliament*, and at the time of his death was engaged on an index to the whole series. He was further a most industrious member of the Bannatyne, Maitland, and Spalding Clubs, and edited for them several of the register-books of the old religious houses of Scotland, with other historical documents of great importance. He published a volume of lectures on *Legal Antiquities* (1872), and was the author of several memoirs, including one of Dean Ramsay. Cosmo Innes died suddenly at Killin, 31st July 1874, in his seventy-sixth year. See the Memoir by his daughter, Mrs Hill Burton (1874).

Innes, Thomas, a Scottish historian, known better as 'Father Innes,' was born in 1662 at Drumgask, on Deeside, Aberdeenshire. At fifteen he was sent to Paris, where he studied at the College of Navarre and the Scots College, of which latter body his eldest brother Lewis (1651-1738) was principal from 1682. Thomas received priest's orders in 1692, and after three years of mission work at Invercayen, Banffshire (1698-1701), returned to Paris, and became prefect of studies in the Scots

College, where he died, 28th January 1744. To pursue his researches he had paid a visit or two to England and Scotland; and Wodrow, who saw him at Edinburgh in 1724, describes him as 'a monkish, bookish person, who meddles with nothing but literature.' Withal he was a staunch Jacobite, but no Ultramontane; not free, indeed, from suspicion of Jansenism. He may justly be looked on as the precursor of Niebuhr and Niebuhr's successors; for his *Critical Essay on the Ancient Inhabitants of Scotland* (2 vols. 1729) is much the earliest of all scientific histories. It was meant for an introduction to a *Civil and Ecclesiastical History of Scotland*, one volume of which, coming down to Columba's death, he prepared for the press, whilst another, bringing down the narrative to 831, was left incomplete. Both were edited for the Spalding Club by Dr Grub in 1853. The aim of the whole work was 'to counteract the inventions of former historians [Hector Boece], and to go to the bottom of the dark contrivances of factious men [George Buchanan] against the sovereignty of our kings;' and, though he thus wrote with a purpose, his honesty and acumen were such that the work retains a permanent value. See the Memoir by Dr Grub prefixed to the reprint of the *Critical Essay* ('Historians of Scotland' series, vol. viii. 1879).

Innocent, the name of thirteen popes, the most remarkable of whom are the following.—**INNOCENT I.**, a native of Albano, was elected Bishop of Rome in 402. Next to the pontificate of Leo the Great that of Innocent forms the most important epoch in the history of the relations of the see of Rome with the other churches, both of the East and of the West. He was earnest and vigorous in enforcing the celibacy of the clergy. He maintained with a firm hand the right of the Bishop of Rome to receive and to judge appeals from other churches, and his letters abound with assertions of universal jurisdiction, to which Catholics appeal as early evidence of the Roman primacy. Innocent I. died in 417, and was canonised.—For Innocent II. see **POPE, ANTIPOPE.**

INNOCENT III. (**LOTHARIO CONTI**), by far the greatest pope of this name, was born at Anagni in 1161. After a course of much distinction at Paris, Bologna, and Rome, he was made cardinal; and eventually in 1198 was elected, at the unprecedentedly early age of thirty-seven, a successor of Pope Celestine III. His pontificate is justly regarded as the culminating point of the temporal as well as the spiritual supremacy of the Roman see; under the impulse of his ardent but disinterested zeal for the glory of the church, almost every state and kingdom was brought into subjection. In Italy, during the minority of Frederick II., who was a ward of Innocent's, the authority of the pope within his own states was fully consolidated, and his influence among the other states of Italy was confirmed and extended. In Germany he adjudicated with authority upon the rival claims of Otto the Guelph and Philip of Swabia; in France he compelled Philip Augustus to dismiss Agnes de Meranie, whom he had unlawfully married, and to take back Ingeburga. In Spain he exercised a similar authority over the king of Leon. The history of his conflict with and triumph over John of England displays in a stronger light the extent of his pretensions and the completeness of his supremacy. Even the king of Armenia, Leo, received his legates. And, as if in order that nothing might be wanting to the completeness of his authority throughout the then known world, the Latin conquest of Constantinople and the establishment of the Latin kingdom of Jerusalem put an end, at least during his pontificate, to the shadowy pretensions of the eastern rivals of his

power, spiritual as well as temporal. His views of the absoluteness of the authority of the church within her own dominion were no less unbending than his notion of the universality of its extent. To him every offence against religion was a crime against society, and in his ideal Christian republic every heresy was a rebellion which it was the duty of the rulers to resist and repress. It was at his call, therefore, that the crusade against the Albigenses was organised and undertaken. As an ecclesiastical administrator Innocent holds a high place in his order. He was a vigorous guardian of public and private morality, a steady protector of the weak, zealous in the repression of simony and other abuses of the time. He prohibited the arbitrary multiplication of religious orders by private authority, but he lent all the force of his power and influence to the remarkable spiritual movement in which the two great orders, the Franciscan and the Dominican, had their origin. It was under him that the celebrated fourth Lateran Council was held in 1215. In the following year he was seized with his fatal illness, and died in July at Perugia at the early age of fifty-six. His works embrace sermons, a remarkable treatise on the *Misery of the Condition of Man*, and a large number of letters. The 'golden sequence' 'Veni, sancte Spiritus' has been attributed to him by some. It is from his letters and his decretals alone that the character of the age and the true significance of the church policy of this extraordinary man can be fully understood. However earnestly men may dissent from these views, no student of mediæval history will refuse to accept Dean Milman's verdict on the career of Innocent III. that 'his high and blameless, and, in some respects, wise and gentle character, seems to approach more nearly than any one of the whole succession of Roman bishops to the ideal light of a supreme pontiff;' and that 'in him, if ever, may seem to be realised the churchman's highest conception of a vicar of Christ.'

See Milman's *Latin Christianity*, vol. v.; Jorry's *Histoire du Pape Innocent III.* (1853); and the works in German by F. Hurter (1834-42), Deutsch (1876), Schwemer (1882), and Brisehar (1883).

INNOCENT XI. (**BENEDETTO ODESCALCHI**), born at Como in 1611 and elected in 1676, was one of the most distinguished among the popes of the 17th century. He was a vigorous and judicious reformer; but his historical celebrity is mainly owing to his contest with Louis XIV. The dispute began with an attempt on the part of the pope to put an end to the abuse of the king's keeping sees vacant, in virtue of what was called the *Droit de Regale*, and appropriating their revenues. The resistance to this attempt drew forth the celebrated declarations of the French clergy as to the Gallican Liberties. But the actual conflict regarded the immunities enjoyed by the foreign ambassadors residing in Rome, and especially the right of asylum, which they claimed not only for their own residences, but also for the adjoining district. These districts had gradually become so many nests of crime, and of fraud upon the revenue; and the pope gave notice that he would not thereafter receive the credentials of any new ambassador who should not renounce these abusive claims. The great powers murmured at this threat, but it was with France that the crisis occurred. Louis XIV. instructed his new ambassador to maintain the dignity of France, and sent a large body of military and naval officers to support his pretensions. Innocent persisted in refusing to grant an audience to the ambassador, Louis, in reprisal, seized on the papal territory of Avignon; but the pope was immovable, and the dispute was not adjusted till the following pontificate. Innocent died in 1689. The pope of Brown-

ing's *Ring and the Book* was Innocent XII. (Pignatelli), pope in 1691-1700.

Innocents, HOLY. See CHILDREMAN.

Innominate Artery (*Arteria innominata*) is the first large branch given off from the arch of the Aorta (q.v.).

Innominate Bone. See PELVIS.

Innsbruck, the capital of Tyrol, 100 miles by rail S. of Munich, stands on the Inn at its junction with the Sill, 1880 feet above sea-level, surrounded and overhung by mountains ranging from 7500 to 8500 feet high. It is a beautiful place, with broad tree-shaded streets, arcaded shops, and four squares adorned with statues. The Franciscan church, or Hoikirche, built in the Renaissance style in 1553-63, contains a beautiful and elaborate monument to the Emperor Maximilian I. (who, however, is buried in Vienna). It consists of a marble sarcophagus supporting the emperor's effigy in bronze, in a kneeling posture; while on both sides of the aisle are twenty-eight bronze figures of royal (mostly Hapsburg) personages, by Peter Vischer and other German artists. In the same church are monuments to Andreas Hofer and his comrades Speckbacher and Haspinger, and to the Tyrolese who fell in the wars against France (1796-1809). The parish church of St James has a picture of the Virgin by Lucas Cranach. The other chief buildings are the imperial castle, built by Maximilian I. and restored by Maria Theresa in 1766-70; the 'Golden Roof Palace'; the national museum, the Ferdinandenm.; and the university (founded in 1677, and, after several vicissitudes, organised anew in 1826), which has the usual four faculties and upwards of 800 students and 100 professors and lecturers. To the university are attached a library of 92,000 volumes, a botanical garden especially rich in Alpine flora, and the usual museums, laboratories, &c. Amongst the eight monasteries of Innsbruck is the first that the Capuchins founded in Germany (1594). Innsbruck carries on manufactures of woollen cloth, machines, and glass, and glass-painting. It is much visited by tourists in the summer. Pop. (1890) 23,320; or, including the suburbs of Hotting and Wilten, 35,800. Innsbruck has always been a place of some commercial importance, owing to its situation at the ford across the Inn and at the head of the Brenner Pass to Italy. The Romans had here their principal colony in Rhaetia. From 1180 the town belonged to the Counts of Meran; in 1363 it passed with Tyrol to Austria. The stormiest period of its history fell in the days of Hofer (q.v.). See Gwercber, *Innsbruck, and dessen Umgehung* (1880).

Inns of Court, the name given to certain voluntary societies which have the exclusive right of calling persons to the English bar. These societies had their origin in the 13th century, when the clergy ceased to practise in the law-courts, and their place was taken by lay professors, 'apprentices,' and students of law who congregated in the neighbourhood of Westminster. There are four Inns of Court—Lincoln's Inn, the Inner Temple, the Middle Temple, and Gray's Inn. Each possesses a dining-hall, library, and chapel, the Temple Church being used as a chapel by both the societies which take their name from the buildings which once belonged to the Knights Templars. Each inn derives a considerable income from houses and chambers occupied by barristers and others, and each is governed by an irresponsible body called the Benchers. New members of this body, who are usually judges or senior counsel, are chosen by the existing members. The inns possess equal privileges; since 1855, when a royal commission reported on their revenues and constitution, they

have joined in providing lectures for the benefit of students, and in examining candidates for admission to the bar. They have discretion to admit or refuse any candidate without assigning their reasons; but no objection is made to the admission of any person of good character. Each inn exercises discipline over its own members, and has power to disbar them—i.e. to withdraw from them the right to practise; but there is an appeal to the judges from the decision of the benchers. The right of disbarring is exercised only in the case of persons guilty of criminal offences or gross professional misconduct; a formal inquiry is held, but the results of the investigation are not made public. Serjeants' Inn was formerly a society composed of barristers and judges belonging to the 'order of the cof'; but this inn was abolished in 1877. The smaller societies, sometimes called Inns of Chancery, have never been of any great importance; their buildings have passed into the possession of one or other of the Inns of Court, or have become the property of small private societies of solicitors, &c. Staple Inn and Clement's Inn are interesting by reason of the collegiate character of their buildings. For further information, see the Report of the Commission of 1855. The steward of any of the Inns of Court will furnish intending candidates for the bar with information as to the terms of admission, &c. See BARRISTER, and Pease's *History of the Inns of Court* (1848).

The society known as the King's Inns in Dublin performs the duties of an Inn of Court in relation to the Irish bar. The Scottish bar is organised on an entirely different plan (see ADVOCATE).

Innuendo, a part of a pleading in cases of libel and slander, pointing out what and who was meant by the libellous matter or description.

Inoculation ('engrafting'), the communication of disease to a healthy subject by the introduction of a specific germ or animal poison into his system by puncture or otherwise, originally used of the inoculation of smallpox (for preventive inoculation, see BACTERIA, GERM, ANTHRAX, DIPHTHERIA, HYDROPHOBIA). If the matter of a smallpox pustule, taken after the commencement of the eighth day, be inserted in or beneath the skin of a person who has not previously suffered from smallpox, the following phenomena are induced: (1) Local inflammation is set up; (2) on the seventh or eighth day there is fever similar to that of smallpox; and (3) after the lapse of three more days there is a more or less abundant eruption of pustules. This process is termed inoculation, and the disease thus produced is denominated inoculated smallpox. The disease produced in this artificial manner is much simpler and less dangerous than ordinary smallpox; and as it was an almost certain means of preventing a subsequent attack of the ordinary disease, inoculation was much practised till it was superseded in the beginning of this century by Jenner's introduction of vaccination. The importance of inoculation was recognised in the East at a very early period, the Chinese practising it from the 6th century, and the Brahmins from a very remote antiquity. In Persia, Armenia, and Georgia it was in use, and it is even said to have been employed in Scotland and Wales. It was not, however, till Lady Mary Wortley Montagu wrote her celebrated letter from Adrianople in 1717 that the operation became generally known in England. In that letter she writes: 'The smallpox, so fatal and so general amongst us, is here entirely harmless, by the invention of *ingrafting*, which is the term they give it. Every year thousands undergo the operation. There is no example of any one that has died in it, and you may believe that I am very well

satisfied of the safety of the experiment, since I intend to try it on my dear little son.' Four years afterwards she had her daughter publicly inoculated in England; the experiment was then performed successfully on six condemned criminals at Newgate, and on the strength of these successful cases two children of Caroline, Princess of Wales, were inoculated, which gave a sanction to the practice.

Inoculation was not, however, thoroughly established for more than a quarter of a century after its introduction. It met with virulent opposition both from the medical profession and the clergy. A sermon is extant which was preached in 1722, by the Rev. Edward Massey, in which it is asserted that 'Job's distemper was confluent smallpox, and that he had been inoculated by the devil.' The great drawback to inoculation turned out, however, to be this: while it was invaluable to him who underwent the operation, and completely guarded him from the natural disease in its severe form, its effect upon the community at large was extremely pernicious in keeping alive the natural disease, and increasing its spread amongst those who were not protected by inoculation. While one in five or six of those who took the natural disease died, the average number of deaths at the Inoculation Hospital was only 3 in 1000; and yet, according to the authority of Heberden, in every thousand deaths within the bills of mortality in the first thirty years of the 18th century (before inoculation was at all general) only seventy-four were due to smallpox. The deaths from this disease amounted to 95 in 1000 during the last thirty years of the century; so that, notwithstanding the preservative effects of inoculation on almost all who were operated on, the total number of deaths from this disease increased in one hundred years in the ratio of about 5 to 4. At the beginning of the 18th century about one-fourteenth of the population died of smallpox; whereas at the latter end of the same century the number (notwithstanding, or perhaps rather in consequence of, inoculation) had increased to one-tenth; and this immense consumption of human lives was not the total evil, for many survivors were left with the partial or entire loss of sight and with constitutions destroyed. The benefits which were expected from inoculation were far from being realised, and smallpox would doubtless have gone on increasing in its destructive power if it had not been checked by Jenner's discovery of Vaccination (q.v.). Inoculation was forbidden by law in 1840.

Inowracław, called also **JUNG BRESLAW** ('Young Breslau'), a town of Prussia, is situated near the Polish frontier, 66 miles N.E. of Posen. Its chief industries are salt mining, the manufacture of salt and machines, and iron-founding. Pop. (1875) 9139; (1885) 13,548.

In partibus infidelium (Lat., 'in the regions of the unbelievers'). Titular bishops in the Church of Rome were from the 13th century until the pontificate of Leo XIII. styled bishops *in partibus infidelium*. They were originally bishops who had no diocese, and took their titles from places where there was no longer a bishop's see. The usage originated after the Greek schism, and became general in the time of the Crusades. The places conquered by the crusaders in the East were furnished with Roman Catholic bishops; but when these conquests were again lost the popes continued to appoint and consecrate the bishops as a continual protest against the power which had prevailed over their alleged right, and to signify their hope of restitution. But in Britain, the assumption of territorial titles being illegal and dangerous, the Roman Catholic bishops actu-

ally resident long bore titles derived from such distant places. In 1850 their assumption of titles from their actual sees gave prodigious offence in England, and led to the passing of the *Ecclesiastical Titles Bill* (q.v.), which, however, remained a dead letter, and was repealed in 1871.

Inquest. See CORONER.

Inquisition, called also 'the Holy Office,' a tribunal in the Roman Catholic Church for the discovery, repression, and punishment of heresy, unbelief, and other offences against religion. From the very first establishment of Christianity as the religion of the Roman empire laws more or less severe existed, as in most of the ancient religions, for the repression and punishment of dissent from the national creed; and the emperors Theodosius and Justinian appointed officials called 'inquisitors,' whose special duty it was to discover and to prosecute before the civil tribunals offences of this class. The ecclesiastical cognisance of heresy and its punishment by spiritual censures belonged to the bishop or the episcopal synod; but no special machinery for the purpose was devised until the spread in the 11th and 12th centuries of certain sects, reputed dangerous alike to the state and to the church—the Cathari, Waldenses, and Albigenses—excited the alarm of the civil as well as of the ecclesiastical authorities. In the then condition of the public mind, however differently it is now constituted, heresy was regarded as a crime against the state, no less than against the church. An extraordinary commission was sent by Pope Innocent III. into the south of France to aid the local authorities in checking the spread of the Albigensian heresy. The fourth Lateran Council (1215) earnestly impressed both on bishops and magistrates the necessity of increased vigilance against heresy; and a council held at Toulouse directed that in each parish the priest and two or three laymen of good repute should be appointed to examine and report to the bishop all such offences discovered within the district.

So far, however, there was no *permanant* court distinct from those of the bishops; but under Innocent IV., in 1248, a special tribunal for the purpose was instituted, the chief direction of which was vested in the then recently-established Dominican Order. The Inquisition thus constituted became a general instead of as previously a local tribunal; and it was introduced in succession into Italy, Spain, Germany, and the southern provinces of France. So long, moreover, as this constitution remained it must be regarded as a strictly papal tribunal. Accordingly, over the French and German Inquisition of the following century the popes exercised full authority, receiving appeals against the rigour of local tribunals, and censuring or even depriving the inquisitor for undue severity. In France the Inquisition was discontinued under Philip the Fair; and though an attempt was made under Henry II. to revive it against the Huguenots the effort was unsuccessful. In Germany, on the appearance of the Beghards (q.v.) in the beginning of the 14th century, the Inquisition came into active operation, and inquisitors for Germany were named at intervals by various popes, as Urban V., Gregory XI., Boniface IX., Innocent VIII., down to the Reformation, when it fell into disuse. In England it was never received, all the proceedings against heresy being reserved to the ordinary tribunals. In Poland, though established in 1327, it had but a brief existence.

It is the history of the Inquisition as it existed in Spain, Portugal, and their dependencies that has absorbed almost entirely the real interest of

this painful subject. As an ordinary tribunal similar to those of other countries it had existed in Spain from an early period. Its functions, however, in these times were little more than nominal; but early in the reign of Ferdinand and Isabella, in consequence of the alarms created by the alleged discovery of a plot among the Jews and the Jewish converts—who had been required either to emigrate or to conform to Christianity—to overthrow the government, an application was made to the pope, Sixtus IV., to permit its reorganisation (1478); but in reviving the tribunal the crown assumed to itself the right of appointing the inquisitors, and, in truth, of controlling the entire action of the tribunal. From this date forwards Catholic writers regard the Spanish Inquisition as a state-tribunal, a character which is recognised by Ranke, Guizot, Leo, and even the great anti-papal authority Llorente; and in dissociating the church generally and the Roman see itself from that state-tribunal, Catholics refer to the bulls of the pope, Sixtus IV., protesting against it. Notwithstanding this protest, however, the Spanish crown maintained its assumption. Inquisitors were appointed, and in 1483 the tribunal commenced its terrible career under Thomas de Torquemada. The popes, feeling their protest unsuccessful, were compelled from considerations of prudence to tolerate what they were powerless to suppress; but several papal enactments are enumerated by Catholics, the object of which was to control the arbitrary action of the tribunal and to mitigate the rigour and injustice of its proceedings. Unhappily these measures were ineffective to control the fanatical activity of the local judges. The number of victims, as stated by Llorente, the popular historian of the Inquisition, is positively appalling. He affirms that during the sixteen years of Torquemada's tenure of office nearly 9000 were condemned to the flames. The second head of the Inquisition, Diego Deza, in eight years, according to the same writer, put above 1600 to a similar death; and so for the other successive inquisitors-general. But Catholics loudly protest against the credibility of these fearful allegations. It is impossible not to see that Llorente was a violent partisan; and it is alleged that in his work on the Basque Provinces he had already proved himself a venal and unscrupulous fabricator. Although, therefore, he has made it impossible to disprove his accuracy by appealing to the original papers, which he himself destroyed, yet his Catholic critics—as Hefele in his *Life of Cardinal Ximenes*—have produced from his own work many examples of contradictory and exaggerated statements; Prescott, in his *Ferdinand and Isabella* (iii. 467-70), has pointed out many similar instances; and Ranke does not hesitate (*Fürsten und Völker von Süd-europa*, i. 212) to impeach his honesty. Still, with all the deductions which it is possible to make, the working of the Inquisition in Spain and in its dependencies even in the New World involves an amount of cruelty which it is impossible to contemplate without horror. When it was attempted to introduce it into Naples Pope Paul III., in 1546, exhorted the Neapolitans to resist its introduction, 'because it was excessively severe and refused to moderate its rigour by the example of the Roman tribunal' (Llorente, ii. 147). Pius IV. in 1563 addressed a similar exhortation on the same ground to the Milanese (*ibid.*, ii. 237); and even the most bigoted Catholics unanimously confess and repudiate the barbarities which dishonoured religion by assuming its semblance and its name.

The procedure of the Inquisition deserves a brief notice. The party, if suspected of heresy,

or denounced as guilty, was liable to be arrested and detained in prison, only to be brought to trial when it might seem fit to his judges. The proceedings were conducted secretly. He was not confronted with his accusers, nor were their names even then made known to him. The evidence of an accomplice was admissible, and the accused himself was liable to be put to the torture in order to extort a confession of his guilt. The punishments to which, if found guilty, he was liable were death by fire, as exemplified in the terrible *Auto da Fé* (q.v.), or on the scaffold, imprisonment in the galleys for life or for a limited period, forfeiture of property, civil infamy, and, in minor cases, retraction and public penance. It is fair to recollect that some of the usages were but the ordinary procedures in all the courts of the age, whether civil or ecclesiastical.

The rigour of the Spanish Inquisition abated in the later part of the 17th century. In the reign of Charles III. it was forbidden to punish capitally without the royal warrant; and in 1770 the royal authority was required as a condition even for an arrest. From 1808, under King Joseph Bonaparte, the Inquisition was suppressed until the Restoration; it was again suppressed on the establishment of the constitution of 1820; but it was partially restored in 1825; nor was it till 1834 and 1835 that it was finally abolished in Spain, its property being applied to the liquidation of the national debt.

The Inquisition was established in Portugal in 1557, and its jurisdiction was extended to the Portuguese colonies in India. The rigour of its processes, however, was much mitigated in the 18th century, and under John VI. it fell altogether into disuse.

The Inquisition in Rome and the Papal States never ceased, from the time of its establishment, to exercise a severe and watchful control over heresy, or the suspicion of heresy, which offence was punished by imprisonment and civil disabilities; but of capital sentences for heresy the history of the Roman Inquisition presents few instances, and, according to Balmez (*On Civilisation*, p. 156), that tribunal 'has never been known to order the execution of a capital sentence for the crime of heresy. The tribunal still exists under the direction of a congregation, but its action is confined to the examination of books and the trial of ecclesiastical offences and questions of church law; and since the Italian occupation of Rome in 1870 its supreme jurisdiction is limited to the Vatican.

See Llorente's *Historia Crítica de la Inquisición* (Fr. trans. 4 vols. 1817); Comte Joseph de Maistre's *Letters on the Spanish Inquisition* (Eng. trans. 1851); Prescott's *Ferdinand and Isabella*; Motley's works; Hefele's *Cardinal Ximenes*; Balmez, *Catholicism and Protestantism*; Hofman, *Geschichte der Inquisition* (1878); Mohner, *L'Inquisition double moti de la France au XIII. et au XIV. Siècle* (1880); H. C. Lea's *History of the Inquisition of the Middle Ages* (3 vols. 1888).

Insanity. No good definition of insanity has ever been given in any language, nor is it possible. Any definition that would have accurately fitted what was understood as insanity in Shakespeare's time would be quite inadequate now, for we count men insane who would have passed muster well enough in the 16th century. Another difficulty of definition consists in this, that the very same mental symptoms may exist in two people, and in one they may constitute true insanity, while in the other they may only be one of the brain symptoms of a fever. And if there is one thing better understood about insanity now than formerly, it is that there is no exact line of demarcation between insanity and sanity any more than there is between

light and darkness. There is an undefined borderland through which most cases of insanity pass, between technical and legal sanity and insanity. But while this is true, there is no truth and little sense in the common saying that 'all are more or less insane on some point.' Such a statement entirely mistakes the real significance of insanity as a *disease*, and is a pernicious fallacy begotten of ignorance. Insanity may be reasonably described, according to the scientific ideas of our time, as 'such an alteration in any or all of the mental functions of the brain as makes a man unfit from this cause to do his work or manage his affairs, or mingle in the society of his fellow-men, or which makes him unsafe to himself or others or to society, this alteration not being solely the result of fever, but being the result of disease or disorder in the working of, or imperfection in the development of that portion of the brain through which mind is manifested.' In defining or describing insanity we wish to exclude the delirium of fevers, comatose conditions, somnambulism, mere eccentricity, hysteria, transitory brain excitements due to religious or other strong emotions, or due to other adequate causes. A mother who loses control over herself when she hears suddenly that a child is dead may be more sane than another who shows no outward sign of emotion on such an occasion.

Tests.—There is or can be no absolute test of insanity—or of sanity, for that matter. Sanity is best proved by normal self-control, and insanity by the loss of it from disease. The presence of one or more insane delusions was at one time the legal test, but it is not a true or scientific one. The 'knowledge of right and wrong' was at one time a legal test of responsibility, in other words of sanity, by the law, but it has long been given up. Half the lunatics know right from wrong in some degree or other.

Mind and Brain.—Insanity cannot be properly studied or in any degree understood except by reference to the mental functions of the brain. A physiological view of mind can alone throw light on the complicated and wondrous phenomena of this disease. No merely metaphysical or subjective view or study of mind seems to help us in the least as to it; the facts are inexplicable on any such view of mind. Looked at from the human and social point of view, no other disease approaches it in the terror it inspires, the sense of helplessness it causes, the deep distress to relatives, and the disruption of all normal social conditions. A scientific view of it alone brings us into the mental and emotional attitude with which civilised humanity now regards disease in general. No progress was made in its study or treatment till physicians came to look at it in precisely the same way as they do ordinary disease. Mind must be regarded by all students of insanity practically as being a 'brain function' which is found in all animals in varying degrees; which in man does not at one time of life exist at all, then is seen to arise in small beginnings like any other function, then gradually to develop, attain maturity, and then fail and eventually disappear—all these conditions of mind being absolutely correlated with the structural development and decay of the mental organ in the brain. It is thus studied and looked on as sensation and motion are studied. The latest physiological and evolutionary studies of mind in relation to brain seem to lead to the conclusion on scientific and not merely *a priori* grounds that it is to the mental organ or centres in the brain that all higher evolution tends. In it are 'represented' every other organ and function of the body, and so they are all in intimate and organic connection with it and its highest function of mind, and so with each other as to make of the organism an

organic unity. If the evolutionists are right, everything that lives tends towards mentalisation, and all the nervous organs of all the types of animal life find their acme in the mental centres of the human brain. The whole of the human brain is not a mental organ. There are centres for motion and sensation and regulation of function, but they are all represented in, and correlated and largely controlled by the mental organ. It clearly resides in the convolutions of the brain. This dominant organ has necessarily become what it is in man through the hereditary influences that have gradually upbuilt it since the beginning of life. This heredity has been largely influenced by external conditions. These have been good and bad throughout the ages, and the bad have left many bad mental results, in so far as natural selection and the struggle for existence have not eradicated them. The mental organ in the human brain has thus become the most complicated, the most delicate, and yet the most potent thing in nature, impressionable to all stimuli from within the body and outside it; reactive in due amount, and yet not unduly if healthy, to all these impressions and stimuli; containing within itself, in a way that yet we are not even able to realise, hereditary qualities, bad and good, from thousands of ancestors. If this is so one is prepared to believe that through evil hereditary influences, and from evil conditions outside it, this organ may often be upset in its normal working. The most important form of such upset is insanity, because it touches the highest brain function. The student of mind physiologically finds on the threshold of his studies that every form of mental energy is just as hereditary as the colour of the hair or the shape of the nose; he finds that volitional power, reasoning acuteness, emotional keenness, moral sensitiveness, good social instincts, retentive memory, and mental resistiveness of all kinds are all transmitted hereditarily. He is therefore prepared to believe that these same laws of heredity have determined the volitional paralysis, the reasoning and the emotional perversions, the losses of memory, and the mental instability which he finds among the insane, and to believe that it is probably the most hereditary of all diseases.

General Symptoms.—The symptoms of insanity are best studied as mental and bodily symptoms. It is only since the disease was studied from the physician's point of view that the bodily symptoms have been specially noticed. Nothing in medicine was ever seen till it was looked for. Nowadays every physician knows that the bodily symptoms and the general condition of the body and its organs are often the most important matters for him to observe and attend to in a case of insanity. He finds few cases of recent insanity without such bodily symptoms. The most common mental symptoms are morbid emotional depression and mental pain, which is the dominant symptom in melancholia. It is an essential law of life that in health the performance of all function yields pleasure. The law is that to live is to energeise, and to energeise is to enjoy life. Except this is so there is abnormality or disease. In many cases of insanity to energeise mentally is to suffer pain. The essential relationship between emotion and action is thus reversed. Another symptom in other cases is an undue emotional exaltation; this is commonly associated with a loss of the great controlling or inhibitory functions of the brain, and occurs in mania. There is morbid brain excitement, commonly exhibited in restless motions or shouting. Such cases may go on to complete loss of any consciousness of all the former brain impressions and mental life. The patient remembers nothing, and does not know his nearest friends. Another most

common symptom is a diminution or loss in the power of attention. This is common to nearly all forms of insanity. Then we have perversion of the reasoning power, as seen most frequently in insane delusions. Like insanity, an insane delusion cannot be defined. It may be said to be a belief in something that would be incredible to ordinary people of the same class, education, or race as the person who expresses it, this resulting from some morbid state of the brain. Insane delusions are common in most cases and varieties of insanity. They are divided into fixed delusions and changing delusions, the former being the most serious and incurable. Some delusions are held by patients in a sort of slack theoretical way, not influencing conduct; others again are keenly held and lead to their logical results in conduct. There may be two 'prophets of the Lord' in an asylum, one of whom will insist on delivering his 'message' on every opportunity to all with whom he comes into contact, will not employ himself in ordinary occupations, and refrains from all amusement; the other will only speak of his delusion when asked about it, will be a capital blacksmith or scrubber of floors, and enjoy thoroughly a dance or a comic song. The origin of insane delusions is one of the most interesting, and often the most obscure of psychological problems. In some cases the process can be clearly traced, being analogous to the process of 'day dreaming' in children. Imagination and fancy are vivid, the reasoning and comparing power is in abeyance, and so the subjective is taken for the objective. Every time a fancy is so looked on it gets more and more 'organised' into a real delusion. Sometimes delusions result from the accentuation of the natural mental temperament by outward circumstances—e.g. when a hunchback of a naturally sensitive, suspicious disposition is in his boyhood annoyed by his fellow-boys at school, the consciousness of his deformity being thus ever brought before him, and when weak health and lack of physical power make him irritable and misanthropic and he then takes a fever, during which he is delirious, and fancies all the time that he hears the old boy-voices of opprobrium—it seems intelligible in such a case that after recovery, but with still a bloodless and weakened brain, he should still hear the voices saying 'hunchback, hunchback.' The hearing of voices when no such exist is an example of a *hallucination*, which is used to denote special sense impressions that have no outward causes. Hallucinations may be of hearing, which are the most common and the most serious as a symptom of incurability if long continued; of sight, the next most common and more likely to be recovered from; of smell and taste, which are rare, and not favourable. Hallucinations and delusions are often connected with and arise out of real sensations, which are misinterpreted by the weakened brain—e.g. a man has been drinking, and has so disordered his stomach, and irritated its lining membrane, that he feels a constant pain there and a bad taste in his mouth, and he concludes that poison has been put into his food, adding these real sensations as proof of his delusion. His mental centre had been disturbed in its working by the drink, so that he could no longer reason clearly and put the true interpretation on the facts.

A distinctive character of an insane delusion is that it cannot be in any way changed or dispelled by the clearest demonstration that it is false. A man thinks he is ruined and a pauper; you bring his bank book and show him that he has £1000 on his account; and you bring the banker with the actual money to him, but you cannot by such means eradicate the false belief. A sane man may have a hallucination (see HALLUCINATIONS), but he knows his 'brain is playing him

a trick,' when ordinary means are taken to demonstrate the unreality of his impression. Another very important and most dangerous symptom in insanity is the tendency towards suicide. This is commonly a symptom in melancholia, and usually goes with a depressed emotional state. But sometimes it exists by itself as a morbid impulse, unreasoning, unaccounted for, unexplainable. Sometimes patients attempt their lives when unconscious of what they are doing, and do not remember what they have done. Patients say that ideas of suicide come into their minds unsuggested in the midst of work and even of enjoyment. A desire to put an end to one's own life is physiologically the furthest away from health of any morbid mental symptom that can possibly occur, for it is a perversion of the primary instinct of all living beings—viz. the love of life, and the desire and effort to protect and preserve it. Without this instinct life would soon end on the earth. It is not any reasoning as to the desirability of life that keeps men and animals alive and drives to unceasing efforts to preserve it, nor is it the pleasure of eating, nor the fear of pain in death. It is the simple innate organic instinct to live which no reasoning can impair in most men. When a man attempts his life, apparently as a calm reasoning conclusion from facts which seem to prove that this is the best thing he can do, in ninety-nine cases out of a hundred the process of reasoning is not the real motive for the act, but the loss of the life instinct which started the reasoning and made the act possible. No doubt the strength of the instinct and of the love of life is much less in some persons and in some races apparently than in others. But such a lessened instinct means a bad heredity and lessened capacity for the struggle for existence. It is twin-brother to a heredity towards ordinary insanity. There may be motives that with civilised men are stronger even than the love of life, and a man with a strong will or under the impulsion of a strong emotion or in a state of despair may certainly take his own life though sane. Suicide is frequently suggested by the sight of the means of self-destruction. There are many persons not insane who cannot see a sharp weapon or go near a precipice without the suggestion of suicide, while many of the insane are entirely unable to resist attempts on their own lives when such means are seen. Some patients will use the utmost cunning to conceal their intention of committing suicide, whilst others will do it most openly. The natural courage of the person comes in very strongly in estimating the actual risk in any case; but the most timid, the most conscientious, who intellectually know it to be wrong, and see that every rational motive goes against it, the most affectionate, who know the terrible anguish it will cause to those they love, the most religious, who fear eternal damnation as its consequence, all equally commit suicide when suffering from insanity with the suicidal impulse. About 1700 persons actually take away their own lives every year in England, the proportion being much higher in some other countries. Alcohol is responsible for very many suicides every year. The same patient very often sticks to the same methods of committing suicide. He will again and again try to hang or poison himself when he has plenty of better chances of cutting his throat. The following are the common methods of suicide in Great Britain in their order of frequency—viz. drowning, hanging, starvation, wounds by firearms, poisoning, precipitation, and choking. But some patients prepare elaborate means and apparatus for the purpose. An American killed himself with a complicated apparatus worked by clockwork, which first put him under chloroform

and then decapitated him; this apparatus having taken him over two years to construct. Suicidal feeling or impulse is often recovered from, and is not a specially bad symptom except as requiring the watching of the patient.

Another mental symptom of insanity very common is impulsiveness, or action in an automatic unreasoning way, sometimes without any conscious intention on the patient's part, and without power of control by the will. A man sees a large plate-glass window, and he hurls a stone through it impulsively. Another cannot resist the impulse to tear his clothes, a third cannot resist the impulse to set a haystack on fire. Uncontrollable impulse naturally goes with diminished volition in insanity. What would be the conduct of most sane men if their wills did not stand between impulse and action? If the will is paralysed, as it is in many cases from disease, their impulse is uncontrolled. Patients may be fully conscious of morbid impulses, may intellectually see their danger or absurdity, and morally may deplore their 'wickedness' in yielding to them, yet have no power to control them; or they may be in a condition of unconsciousness, or false consciousness, during which impulsive acts are done and not remembered afterwards at all. When consciousness returns such people are surprised and incredulous when told that they have smashed furniture or tried to kill their children. A patient once attempted her own life, suddenly smashed a picture, and nearly strangled her attendant, and was amazed when told what she had done. She was a gentle, religious lady of the highest principle. Whenever she passed into this condition of false consciousness during which such impulsive acts were done she would glare at one particular picture on the wall, and would spring at it, so that it had to be removed from the room. She had no particular feeling about it when in her ordinary state of consciousness.

One of the most common and most painful symptoms of insanity is a change of natural affection towards relatives. The mother forgets her sucking child; the sister ceases to love the brother; and the husband dislikes or suspects his wedded wife. This is not universal, but in nearly half the cases of insanity the affective condition is thus perverted or reversed. The memory is not necessarily affected in insanity. In many patients it is exaggerated: things come back with unnatural vividness. A man during simple mania could repeat most of the Psalms and many of Shakespeare's plays, which he never could when well. In some cases the memory brings back only the unpleasantnesses of past life, in others only the pleasant events, and in others there is no memory of past events at all during the attack. It is a constant source of anxiety to relatives whether patients remember the events that have taken place during their attack or their own sayings, feelings, or thoughts then. No rule can be laid down as to this. It depends on the nature of the attack, and especially on whether the power of attention is affected during its continuance. It is certain the memory of events that happened during the attack is usually blurred or distorted or hazy, even though as in some cases the patients affirm they 'can remember everything.' It is frequent that after recovery they speak of the events during the attack and their own feelings then 'as if it were a dream.' Sometimes the affective nature gets changed during an attack not only in regard to persons, but to books, scenery, and food. The appetites become perverted and changed; the social instincts are commonly altered. In a few cases these are intensified, but their usual discrimination is lost. Commonly, a lunatic is unsocial, and some cases are entirely asocial. The

imaginative faculty is usually perverted, this being generally connected with the delusions present. In some cases an attack of insanity is a prolonged 'day-dream,' the condition being one rather of disjointed fancy than of coherent or constructive imagination. The normal law of association of ideas is usually altered. The same ideas do not suggest each other in sanity and insanity. The tendency is in insanity for ideas to suggest grotesque and incongruous things or trains of thought. The habits of life are notably changed in most cases, men and women becoming literally 'not themselves' in their ways and modes of living. The cleanly becomes uncleanly; the orderly man disorderly.

The chief bodily symptoms in insanity are the following. There is scarcely any symptom more common before and in the early stages of attacks than sleeplessness. 'Tired nature's sweet restorer, balmy sleep,' certainly departs when the terrible brain disturbance occurs, or is about to occur. It does not follow that because a man is sleepless he is going to be insane, but almost every kind of insanity is sleepless in its early stages. Nor does it by any means follow that sleeplessness is always the cause of the attack. It is rather in most cases an early symptom. The next bodily symptom in importance is morbidnesses of speech. On the patient's speech we chiefly depend for our diagnosis of most cases. Through it delusions are given expression to; it may be incoherent or partially coherent; it may be over rapid, slow, or entirely absent. A patient at Morningside Asylum never uttered a word for seventeen years, though he could speak quite well but for a delusion he has, and he works well, writes to express his wishes, goes out every Saturday and sees the sights of the town, and behaves mostly like a sane man, save in this particular. Often the conventionalities of speech are lost or dropped in insanity. The articulation of words is often changed. Next in importance to the speech is the expression of the face and eyes. This is given by the most delicate combined muscular and nervous apparatus that exists in nature, being in the most intimate connection with the mental part of the brain, and acting as its chief expositor and interpreter. It would be impossible to describe all the changes that take place in the expression of the eyes and faces of the insane. In the depressed and demented cases the eye loses its lustre and brilliancy; in maniacal cases it has abnormal feverish brilliancy; the pupil enlarging and the eyelids being drawn too far apart produce staring, the whole of the cornea being seen. In regard to the expression of the face, we see how the 'mind muscles' alter the man when in action and repose, in health and sickness. The natural expression is greatly changed, and little beauty of feature survives during acute attacks. The conventional control over the outward expression of the emotions is lost, and the face accurately shows the state of the melancholic, the maniacal, or the demented patient. Often too the fixed delusion shows in the patient's face. Indeed there are many cases where the expression caused by changed emotion during the first part of an attack gets fixed, and remains so after the patient has really ceased to feel the morbid emotion at all. A lady who had been intensely melancholy in feeling for five years then sank into incurable weakness of mind, and completely lost her keen feeling and memory, but for the next twenty years, till her death, the muscles of her face and her attitude expressed the melancholy which she did not feel. She constantly wrung her hands, and could not tell why she did so. There was in fact an automatic 'muscular misery.' There are important indications of certain kinds of insanity in the state of the pupils too,

In the muscular movements of the body an insane patient will often indicate his emotions far more than a sane man would do.

The skin, the hair, the perspiration, the liver, the heart, and the kidneys are often changed in working, and the temperature of the body altered during an acute or recent attack of insanity. Before an attack there are often pains or uneasy feelings in the head, which disappear when it comes on. The bodily sensations are notably dulled in most acute attacks. Patients will often cut or bruise themselves or undergo operations without feelings of pain. The body weight is rapidly lost, and the general nutrition almost invariably suffers. Thus it is seen that disease cannot attack the highest organ and function without affecting also almost every other organ and function of the body. The higher brain centres and the peripheral organs act and react on each other, so that when the one is disturbed in action the others suffer.

Forms, Varieties, and Classification of Insanity.—One case of insanity may differ from another in all its symptoms, mental and bodily, so that the two may have almost nothing in common except that in both the mind is affected from brain disorder. One case may be so near sanity that it needs an expert to say there is anything wrong; while another is 'raving mad' to any eye. One case is conscious that his mind is affected; another, much worse, believes he was never so well in his life. One case needs no control, and can do some work; another needs the control of others in all respects, and cannot do anything. One is perfectly safe to himself and others, while another is as dangerous as the popular 'madman' is supposed to be—as a matter of fact, half the insane are not dangerous at all, and very few of them are as dangerous as they are popularly supposed to be. The popular idea that the insane are all much alike is utterly wrong. Nothing is more common than for the doctor of an asylum to be asked such questions as—'Do your patients know where they are?' 'Are they the better for the visits of friends?' 'Do they enjoy each other's society?' 'Are they happy?' 'Do they like or dislike you?' 'Are they nice to do with?' To one and all of such questions the answer has to be—'They differ entirely from each other in all these respects.' Where there are differences it is the business of science to classify. Insanity has been classified most variously, but at the present time only two of the classifications can be said to hold the field. The one is that in which the prevailing mental symptoms are taken as the basis of classification, the cases with similar mental symptoms being thrown together into each group. This was first done by Philippe Pinel, who was born in 1745 and died in 1826, was the physician to the great hospital for the insane at Paris, the Bicêtre, and who during the revolutionary period asked and got permission to remove the chains and manacles from his patients there. It is the 'mental classification,' and is used more or less by all physicians. The other classification was that devised by David Skae, who was born in 1814 and died in 1873, and was physician to the Royal Edinburgh Asylum for twenty seven years, exercising during that time an enormous influence on the growth of the mental department of medicine, which is called 'alienism' in France, 'psychiatric' in Germany, and commonly medico-psychology in Britain. The 'clinical classification' goes on the principle of selecting a more real, natural, and lasting relationship between the cases than mere mental symptoms. The weak point of the mental classification is that it is one of symptoms only; and a case may change entirely in its symptoms in the course of the same attack. The weak point in the

clinical classification is that it does not cover the whole ground, many cases not being as yet classifiable under any of its divisions. The classification of the future will be a pathological one, which will supersede the two others, but our knowledge of the pathology of the various forms of insanity is not as yet sufficiently accurate to enable such a classification to be made. The forms of insanity under the mental classification, as found in Clouston's *Clinical Lectures on Mental Diseases* (1887), are as follows:

Melancholia, comprising all *states of depression*.—This has emotional depression, or mental pain and sense of ill-being, as its leading and dominant symptom. There may in addition be loss of self-control, insane delusions, which are usually suggested by the depression or impulses towards suicide, as well as incapacity to follow ordinary avocations in melancholia. These distinguish it from sane melancholy. Suicide is the great risk in such cases; four-fifths of melancholics being suicidal. The chief of the bodily symptoms are apt to be thinness, weakness, a low nervous and nutritive tone, and stomach, bowel, and liver derangements. Melancholia forms about 30 per cent. of the insanity sent to asylums; but if the cases not sent to such institutions, but treated at home, are taken into account, it forms probably half the total number. It is by far the most conscious and the most manageable form of recent insanity on the whole, being the form next to sanity. Most other kinds of mental disease begin by some amount of mental depression. Of melancholic patients sent to asylums 54 per cent. recover; but a larger percentage than this recovers if the cases treated at home are also included, because, of course, it is the worst class that require asylum treatment. The recoveries from melancholia are the most complete of all forms of insanity. It would seem to be caused by a more entirely functional and dynamical brain disturbance than any other form of insanity that may leave no trace whatever behind it after recovery.

Mania, comprising all *states of mental exaltation*.—The chief emotional forms of such mental exaltation are joyousness and rage, and are commonly accompanied by muscular excitement, restlessness, sleeplessness; the speech tends to become incoherent, the conduct violent or uncontrolled; there are commonly delusions of many kinds. The symptoms range from a joyous elevation with talkativeness and merely want of common sense and foolish conduct up to complete incoherence, delirium, and 'raving madness' or 'acute mania.' In such acute cases the temperature of the body is raised as in a fever; often there is such rapid loss of body weight that 28 lb. are lost in a week, and the patients even die of the disease in about 8 per cent. of such acute cases; while on the other hand 60 per cent. recover and 30 per cent. become incurable. The brain is very congested and hyperactive in acute mania, but this does not result from inflammation.

Folie Circulaire, or *states of regular alternation* between melancholia and mania, forms a small but distinct variety of insanity. More or less periodicity and tendency to recurrence and relapse is unfortunately a very common symptom in most attacks of insanity, and the period between each aggravation is often about four weeks; hence the name 'lunacy.' It is hardly necessary to say that the moon has nothing whatever to do with insanity. Nothing is more discouraging to those in charge of cases than this relapsing tendency; but it should not lead to despair of ultimate recovery, unless such relapses become regular and frequent for years. When this is the case the prospects of recovery are bad. Patients suffering from alternating insanity lead

three lives—one when they are in the melancholy stage, another when in the joyous, elevated stage, and another when nearly sane.

Monomania, or delusional insanity, is that form where insane delusions are the chief signs of the mental aberration. A man may have such insane beliefs of all kinds, utterly unfounded in fact and utterly unchangeable by the plainest demonstration of fact that they are false, without any general depression of mind or exaltation. The intellect is chiefly affected rather than the affective nature in such a case. There are almost no cases of a literal monomania or a morbid false belief on one subject alone. The delusions are morbid in a particular direction, the chief forms being *monomania of grandeur or pride, of aversion agencies, and of unfounded suspicions*. Electricity, mesmerism, telephones, gases, noises made by imaginary persecutors are the common subjects of the second form; while utterly perverse interpretations of the conduct of friends or strangers is the common form of the latter. The two together are sometimes classed as *monomania of persecution*. Hallucinations of the senses—i.e. imaginary sights, sounds, smells, and tastes—are very common in this form of insanity. It is not very curable when the delusions get fixed; but in the early stage, and when dependent on derangements of the bodily health, it is often recovered from. This form of insanity, and delusion generally, is of great importance from a legal point of view, but not so much from the medical side.

Dementia, or conditions of general mental enfeeblement, is the state of mind where the memory is impaired, the reasoning weakened, the feeling diminished, the will especially lacking, the attention and curiosity far below normal, these changes having occurred in a person who had at one time been normally constituted. It is in fact silliness, want of mental force, imbecility not congenital but acquired. This does not usually occur as the first symptom of an attack of insanity, but as the sequel to mania—or, more rarely, melancholia—when it is not recovered from; hence it is commonly called *secondary dementia*. It is in fact the inevitable stage in which these diseases end. The demented patients live on for many years sometimes. The most complete form of dementia occurs after mania that has not been recovered from in adolescence. Dementia is in fact a premature mental death with persisting bodily life.

Stupor embraces those cases where there is mental torpor, in which impressions on the senses produce no effect, the patient neither speaking nor taking notice of anything, and having no volition except to resist, but being able to stand, and walk, and eat. Trance and catalepsy are forms of stupor. The bodily functions are all lethargic in stupor, the heart's action low, the body cold, and the muscles flabby. Stupor commonly occurs in young people of both sexes, and is very curable, 50 per cent. recovering. It sometimes attracts popular wonder and attention, which is very bad for the patient. In some cases it results from profound and terrible shocks which paralyse mind and body. In some cases patients remember all that occurred when they appeared to be taking no notice whatever, and in others the time during which the stupor lasted was a blank to them afterwards.

Impulsive Insanity, or states of defective control, is the last or most recently invented division of the mental classification. In some ways it is the most interesting of all, inasmuch as will is the highest and most essential of all the mental faculties, and volitional disturbances have a closer relationship to morals, law, social life, and conduct than any other aspect of insanity. It is often seen that the

children of insane or drunken parents are lacking in the normal power of control and in their perception of the sense of right and wrong, their conduct being apt to be impulsive and not guided by reasonable motives. Evolutionally the highest of all qualities is thus lessened in amount, this tending towards a disruption and destruction of organised society. If lack of control, criminality, and action from impulse became hereditary and general, society would fall to pieces. All forms of insanity are more or less distinguished by lessened control, but there are persons without general depression or excitement, without insane delusions, without enfeeblement of mind, who will suddenly, and not in obedience to any sane motive, smash furniture, tear clothing, steal, set things on fire, obey gross animal impulses, or kill themselves or others, having no power of control to prevent themselves from doing these things. We now know that certain regions of the brain and nervous centres have as their function the control of other portions, quickening the pace of action or stopping it. In the very highest regions of the brain we find the function of mental inhibition. This controls mental action in other portions of the brain convolutions. In this form of insanity it is supposed that the inhibitory controlling portions or 'centres of mental inhibition' have lost their power. It is as if one's power of controlling the act of coughing on very inadequate irritation was lost. Every minutest point of dust entering the larynx would set up coughing, which would go on independently of the will altogether, as an automatic 'reflex' act. In many of the cases of impulsive insanity the mental portions of the brain act automatically without any controlling action by the inhibiting centres. It is a pitiful and most suggestive thing to see a human being who knows right from wrong, and earnestly desires to do the one and avoid the other, compelled by morbid impulses to act wrongly, all the while bewailing the diseased necessity that is thus laid upon him. The physician frequently sees such a case. Especially is this sight pathetic when the morbid impulse is to take away his own life or that of some one dearer to him than life itself. Such impulsive insanity is often set up in hereditarily unstable brains by weak health and by alcohol. They are often curable. The so-called 'moral insanity' is just one variety of this form of mental disease where the moral sense is absent from disease, and the power of doing right non-existent, while the impulses are all towards immorality.

The clinical varieties of insanity are headed by *general paralysis*, a specific disease of those portions of the brain that subserve mind and motion. It is always incurable, getting progressively worse, gradually impairing and at length destroying speech, motion, mind, and, usually in about three years' time, life itself. In this form of insanity patients commonly have extravagant delusions of wealth and power. It is found chiefly in the male sex, in large cities and manufacturing places, and as yet is almost unknown in the Highlands and the country districts of Ireland. It is a disease of modern life, and is proved to be increasing. *Paralytic insanity* is that connected with apoplexies, softenings and tumours of the brain, which cause ordinary paralysis first, and one form of dementia afterwards. *Epileptic insanity* is that accompanying epilepsy in so many cases. It is often attended by great violence and irritability, and by danger to those around the patient. Many murders are committed by insane epileptics. It is now much more manageable than formerly under modern medical treatment, but is apt to recur after apparent recovery. It prevails most variously in different parts of the country. In Scotland only 7 per cent.

of the insanity is epileptic; in some southern and midland counties of England 25 per cent. is of this character. The true cause of this difference is unknown. *Syphilitic insanity* is the result of brain-poisoning by this terrible scourge of humanity. *Alcoholic insanity* is a very frequent form indeed. Alcohol is the exciting cause of from 15 to 20 per cent. of all insanity; but all the mental disease caused by alcohol is not alcoholic insanity. There can be no doubt that some brains are so prone by heredity to be upset in their mental function that it takes little to do it. If it is not a quarrel with a friend, it is a spree on bad liquor. True alcoholic insanity always has motor symptoms, such as tremblings, convulsions, impaired speech, &c., except *dipsomania*, one variety where the insanity consists in the craving for excessive use of liquor, and lack of control over this craving. Alcoholic insanity may be intensely acute or very mild, very short in duration or very long continued, or incurable. That caused by prolonged steady soaking is the worst. *Rheumatic* and *gouty insanities* are very rare.

Phthisical insanity, or that connected with consumption, is a very interesting variety. The patients are suspicious and unsocial, and often have no cough or spit or other outward sign of consumption, which may not be discovered till the chest is examined. In some cases it is curable. The tendency to consumption and to insanity are often found in different members of the same family. There are various forms of insanity connected with derangement of the reproductive functions. *Uterine, amenorrhoeal, ovarian, hysterical, and masturbatorial insanities*; while pregnancy, childbirth, and nursing are the causes of the *insanity of pregnancy, puerperal insanity, and lactational insanity*. These form 40 per cent. of mental disease in the female sex. They are the most curable of all forms, recovering in over 80 per cent. of the cases. *Puerperal insanity* occurs commonly within a fortnight of childbirth, and is the most acute and one of the most dangerous to life of all insanities, while the most curable, and is attended by the highest temperatures, sometimes reaching 105°. The different periods of life have each their own form of insanity. *Pubescent and adolescent insanity* is always hereditary, is commonly acute and maniacal, usually has remissions and exacerbations, and recovers in over 60 per cent. of the cases, those not recovering commonly passing into the most typical form of *secondary dementia*. This form of insanity should be treated chiefly by milk diet and exercise. It is one of numerous diseases to which the period of development is subject. *Chlosteric insanity* occurs at the period of the 'change of life.' It is usually melancholic in character, and recovers in 53 per cent. of the cases, under proper treatment and conditions of life. *Senile insanity* is typically seen in the *senile dementia* of extreme old age, when the memory and all the faculties have faded away. But spurts of mental excitement and mental depression, with sleeplessness and unmanageability at home, often occur before final dotage. These are often recovered from. They are a half-way house to dotage or a quick road to it.

A number of rarer and less important clinical varieties of insanity have been described. *Traumatic insanity*, from injuries to head; *uramic insanity*, from thinness of blood; *diabetic insanity*; *insanity from Bright's disease*; *post-febrile insanity*, following all kinds of fevers, especially scarlatina; *the insanity of lead-poisoning*; and *myocardematous insanity*.

Causes of Insanity. There can be no question whatever that a hereditary tendency is the chief predisposing cause of insanity. All sorts of disturbing influences to the brain bring out this pre-

disposition into actual disease. No doubt 70 per cent. of all cases have an insane or neurotic heredity. Epilepsy, drunkenness, all nervous diseases, consumption, too exciting or depressing or exhausting employments, or unfavourable conditions of life in ancestry may cause insanity in the offspring. Marriage of near relatives causes it if the stock is bad; not if it is good. The physical causes of insanity, affecting the body, such as alcohol in excess, produce insanity in four times the proportion which mental and moral causes, such as affliction, losses, love-affairs, and religious excitement, do. For the production of a case of insanity there may be, and there usually is, more than one cause—e.g. (1) a man has a heredity; (2) he is at a critical time of life, or is run down in general health, or takes alcohol in excess; (3) he has a money loss, or domestic affliction just before his attack. A heredity to insanity does not mean a bad brain or a weak mind before the insanity comes on. Often it is quite the contrary. It is not the fools that go off their heads.

Nature of Insanity.—No one now doubts that it is due to disorder of function of a certain portion of the brain—viz. that part of the cortex which is the vehicle of all mental function. This bodily aspect of it should never be lost sight of by physicians and relations. Essentially it in no way differs from many ordinary diseases: it begins, runs a definite course, and ends like many common ailments. It may be brought on by disorder in many other parts of the body, upsetting the brain; but with a sound brain there must be a sound mind. The exact pathology of many forms of insanity has not yet been ascertained; but in 80 or 90 per cent. of the cases that die some abnormality can be found in the brain.

Treatment of Insanity.—*Asylums for the Insane.*—The general principles of modern treatment may be divided into *bodily and mental or moral*. The bodily treatment may be generally said to be to put all the organs and functions right if wrong; to get up the strength and fat of the body—the writer preaches the 'gospel of fatness' for all his insane and nervous patients; to restore the tone and right working of the nervous system; to restore the sleep; to give medicines that determine more blood to the brain in cases where there is too little, and to give those that diminish the brain's blood-supply in those where there is too much; to use suitable baths that soothe nervous irritation, and mineral waters; to invigorate and soothe by life in the open air; and to let off undue and morbid nervous energy by much exercise, gymnastics, and massage in some cases, and to secure complete brain and body rest for others. The mental treatment consists chiefly in careful observation, companionship, control, distraction of the mind from morbid thought and feeling by suitable occupations and amusements, and guarding against the dangers of suicide, homicide, and self-neglect. The whole nursing of insanity is a most difficult task, for which the best bodily, moral, and mental qualifications are needed. In old times, and even up to a very recent date, cruelty, neglect, stripes, and tortures without number were the ordinary means of 'treatment.' Cullen, and all the great authors of his time, prescribe so many 'lashes' as a doctor now does so many drops of physic. Even the very medical means used were made terrifying on purpose—'surprise baths' in which patients were without warning plunged and kept till they were nearly drowned, and 'chairs' in which they were 'rotated' till they fainted. The early Christian theory of an evil spirit having entered into an insane man, which must be 'got out of him,' was at the bottom of much of this treatment, and accounted for the utter want of sympathy shown towards

this class of sufferers. Pinel in France, and William Tuke, a York Quaker, in 1792 simultaneously began the new era of humanity, skill, and science for the insane. The next great landmark of progress was when mechanical restraint, in the shape of strait-jackets, &c., was disused, and the 'non-restraint system' of treatment was adopted. This was between 1825 and 1840, and was the work of Charlesworth and Gairdner Hill of Lincoln Asylum, and Conolly at Hanwell. The next advance was made by imitation of Belgian experience at Gheel, where the insane are largely boarded in private families. If not applicable to all, or even to many in Britain, it showed that the insane were not so dangerous as they had been considered. The next advance took place in Scotland, from 1857, through employing the insane more, classifying them better in asylums, making asylums more 'homes' with 'open-door' departments in them, almost abolishing the use of high-walled, enclosed 'airing courts' in asylums for the exercise of patients, sending them out into the open grounds and on the farms instead, and setting up fully-equipped 'hospital' wards with trained nursing for the special medical treatment of the sick and of the recent acute cases, while quiet incurable cases are boarded in cottages in the country under regular inspection and supervision. We are now fully in the scientific era when we hope by careful study of the brain and its disorders to understand the real nature of the disease and apply our remedies with the certainty and exactitude of science in each case. To secure such treatment for most of the poor, and also for many of the rich, *asylums for the insane* are needful.

Every country in Europe has now provision more or less adequate for the care and treatment of its insane. In Germany and Austria asylums are commonly of two classes; the one for the cure of the curable, near large cities, where the patients only stay for a limited time; and the other for the incurable, larger in size, less costly, and further in the country. The same idea is carried out in France (farm colonies), in Belgium, Holland, and in Great Britain; it will certainly be extended, for it enables economy of management to come in where cost is of no avail for cure, and it enables the curative idea to be realised, however costly, among the smaller numbers and individualised patients who are curable. In England the two great establishments at Caterham and Leavesden, each with over 2000 inmates, are the best examples of establishments for the incurable. That at Darenth, Dartford, is for congenital imbeciles and idiots. All three were built to supply the wants of London. The largest asylum in England is Colney Hatch, which contains 2250 patients. This is far too many to be in one institution if it is for curable patients. One of the best known for its scientific work and practical success is that at Wakefield, containing 1400 patients. The English 'registered hospitals' for private patients fulfil a most important philanthropic function. One of them, that at Cheadle, near Manchester, under Mr Mould's most able and original management, leads the way by treating half its patients (150 out of 280) in real homes in the country; such homes being ordinary villas, farmhouses, country mansions, and seaside residences leased for the purpose. Scotland is honourably distinguished by its early care for the insane. Either in the end of the 18th century or the beginning of the 19th, every considerable town in the country (Edinburgh, Glasgow, Dundee, Aberdeen, Perth, and Dumfries) had erected a 'royal chartered asylum' for itself, through the benevolent efforts of individual citizens or of corporate bodies. These made provision for all their insane, poor and rich alike, each helping the other.

Commonly each royal asylum has two houses or departments, one for the poorer and the other for the richer patients. The system has worked well, and by means of it far more complete provision has been made for the insane of moderate means than in England. The largest institution in Scotland is the Royal Edinburgh Asylum at Morningside and Craiglockhart, which has large accommodation for private patients, paying either the higher or lower rates, as well as for pauper patients.

The United States of America have spent enormous sums to make the best provision possible for the mentally afflicted. As much as £600 a bed has been there spent on several 'state asylums' in New York, New Jersey, and Massachusetts. In most of the states all citizens, rich and poor alike, have the privilege of using the state asylums. The members of the Society of Friends in the state of Pennsylvania were the first to make philanthropic efforts to provide 'hospital' accommodation for the insane, their efforts following at a very short interval the work of Pinel and Tuke. The institutions in the United States are now growing to be as large in size as those in the United Kingdom. One of the most original asylums in the world, in its plan, is that at Kankakee, Illinois. It has 1600 patients, and consists of about twenty houses laid out on the two sides of a 'street,' forming in fact an insane town, all of whose inhabitants resort four times a day to a central dining-room or restaurant for their meals, and where a central ward for the sick and the administration buildings are also situated. The provision for the insane in the southern states, however, is backward and defective; and on the whole, it is generally admitted, even by Americans who have seen its asylums, that Great Britain has led the way in its provisions for the treatment of the insane, and that it is still unsurpassed in the world.

There are 135 public asylums and 117 private asylums now in the United Kingdom. The principles of construction of such buildings have become much more domestic and hospital-like and less prison-like than formerly. Each one should be a *hospital-home*, and the different wards in it should be arranged to suit different classes of patients in different states of mind. In fact the careful 'adaptation of the house to its inhabitants' in every stage of their disease should be carried out. There should be in each one *hospital* wards for special mental and bodily nursing, *convalescent* wards just like homes, wards where the most acute and violent and dangerous can be safely and properly treated without annoying the quiet and convalescent. Every means for suitable companionship and for varied occupation and amusement should be provided. A good asylum should in fact be a series of special model dwellings suited to men and women who need a somewhat different mode of life from ordinary mankind. Good asylums for the richer classes have seaside and country houses where the patients go for change in small parties.

The Lunacy Laws.—For the protection of the property of the insane, laws had to be made at a very early period. The first statute on the subject for England was passed in the reign of Edward II., and for Scotland in the beginning of the 14th century. Both had the same end in view. Property then meant land, and the primary duties of land were to the king and the country. If the man who held it from the king was unfit from mental incapacity to perform these duties, then the king had to resume possession or appoint another to take his place and do them. But the man's state could not be ascertained without a formal inquiry by a responsible official—the Chancellor and the chief object of the early statutes was to provide for such an inquiry. If the man was found to be

idiotic or furious, he along with his property passed into the care of his nearest male relative, and there was an end of him so far as the law went. In time some little care was bestowed on him as a human being, apart from his being an owner of land. The principle was afterwards adopted that the inquiry was to be held before a jury, the issue being determined by them, and the consequences of the verdict being carried out under the direction of the Chancellor. Between 1300 and 1889 at least forty statutes were passed in England relating to the insane, and something like eight or ten in Scotland. The most important of them all was the great English Lunacy Act of 1845, passed through the exertions of Lord Shaftesbury, the philanthropist. Its objects were entirely in the interests of the insane, and its effects have been most beneficial in England, while throughout the civilised world its influence for good has been felt. Under its provisions asylums have been erected for every county in England. A Board of Commissioners was appointed who inspect and report on every asylum, and see every insane person whether in or out of an institution; and every precaution was taken that the insane should be well treated, ill-treatment of them being severely punishable. At least £10,000,000 of capital has been laid out in building asylums, and over £1,500,000 a year besides is expended for the maintenance of their inmates. A new statute in 1889 made certain changes which experience had suggested. The Scotch statute of 1857 was founded on the English Act of 1845. Under it a Board of Commissioners in Lunacy was appointed for Scotland, and provision made for the insane of the counties that had no existing royal asylums. Ireland has a very good asylum system, with inspectors in lunacy. Scotland has much the advantage of England in the ease and economy with which the property of an insane person can be taken care of temporarily or permanently under the charge of a *Curator Bonis*, strictly responsible to the Court of Session. England holds to the old, cumbersome and expensive, but very efficient system of a formal inquiry (*de lunatico inquirendo*) by a 'Master in Lunacy' in each case. If the patient is found incapable of managing his affairs (*non compos mentis*), the Lord Chancellor appoints a 'committee of the person' to see to his comfort and proper treatment, and a 'committee of the estate' to manage his property. In addition to the statutes that regulate the care of the property and the persons of the insane, there are acts that provide for the protection of the public and the safe custody of insane persons who have committed crimes or are specially dangerous, the Criminal Lunacy Statutes—and there are three great establishments for criminal lunatics, one at Broadmoor for England, one at Dundrum for Ireland, and one in connection with Perth Penitentiary for Scotland. About three-fourths of the obviously insane are now in asylums or under committees or curators, the others being boarded under supervision in families, or placed in workhouses. And yet, with the great facility for treating the insane in asylums, such precautions are taken by the law and by the boards of lunacy against their abuse that no case of illegal detention of a sane person on the ground of insanity in a public or private asylum was proved in the exhaustive inquiry into the subject by the select committee of the House of Commons in 1877.

Cureability of Insanity. Taking all the cases now technically reckoned as insanity and sent to asylums, 40 per cent. recover; but many of these are subject to relapses, from which, however, they often recover again, just as people have relapses in rheumatism and bronchitis. But if the slight

mental disturbances not sent to asylums at all, and the cases sent to asylums in which there is no organic brain disease nor very advanced senility, are alone taken, the rate of recovery is at least 70 per cent.

Mortality.—The rate is from 80 to 100 per 1000 of the insane living, or about five times the death-rate among the general population. Insanity is in fact a disease of the brain, from which people die as from other diseases.

Ages at which Insanity occurs most frequently.—Taking the number of persons living at the different ages, and the proportion of persons of the same ages who become insane during each period, we find that insanity occurs most frequently in men from thirty to thirty-five, and in women from fifty to fifty-five. But perhaps a more instructive mode of looking at the ages most liable to insanity is to point out that there are periods specially liable to it—viz. at the end of adolescence, from eighteen to twenty-four, when the organism is just attaining reproductive, that is, organic, perfection, heredity being then the chief cause; at mid-life, from thirty to fifty-five, the worries and strains of life, and the climacteric in women being then the chief causes; and after seventy, the general failure of old age, and especially the deficiency of blood to the brain then resulting from its diseased arteries being the cause.

Is Insanity increasing?—In England the number of the insane known to exist has risen from 36,762 in 1859 to 84,345 in 1889, or from 18·67 to 29·07 to every 10,000 of the population; and in Scotland from 6413 to 11,954, or from 19·8 to 28·9 per 10,000 of the population in the same time. But this increase does not prove a real increase of lunacy. For if we take the newly-registered cases of the disease each year, and compare their numbers with the population, we find it has only risen from 4·5 to 6 per 10,000 of the population in Great Britain in thirty years. It is clear, therefore, that there is an accumulation of the insane from the following causes:—viz. (1) through their being taken better care of; (2) the abundance of good institutions, where all the insane poor can be gratuitously treated; (3) the operation of the lunacy laws; (4) the increasing sensitiveness of public opinion as to the neglect or ill-treatment of insane people; and (5) the widening area of the mental disturbances that are reckoned technical insanity requiring treatment in asylums, all these tending to increase the numbers of the recognised and registered insane. There is in fact no proof that insanity as a whole is increasing; certain forms are no doubt increasing, and presumably other forms are diminishing in amount.

Medico-legal and Social Relations of Insanity.—Few persons have studied carefully the mental state of our criminal population but have come to the conclusion that crime is most closely related to mental defect in very many cases. Could we abolish the latter the former would shrink to small proportions. This does not assume that many or most criminals are technically insane persons. They are merely blood-relations of the insane. The law has been gradually altering its tests as to the amount of insanity that absolves from punishment for crime. Of old a man accused of crime had to be totally delirious or fatuous to be absolved from punishment. Now the power of controlling his actions is being gradually made the test. The law has thus approached, and at last coincides with, the scientific views of insanity. Society should have the keenest interest in the mental condition of its members. Soundness of mind is the most precious possession of a people, for there are innumerable degrees and kinds of mental and moral defects that fall far short of insanity, yet are intimately related to it, hereditarily and psychologically—defects that

weaken a people's power of work, diminish its moral force, and impair its social stability. It is one of the most deeply saddening and terrible of the facts in human history that of the men of genius who have raised and glorified mankind few have been without mental disease in their families, and many have themselves fallen victims to it. If it is true that as yet the mode of human development has been such that to get one man of genius nature had to sacrifice mentally many of his kindred, the world should pay some of the debt it owes to its poets and thinkers by an ungrudging care of such victims. To produce in the human brain the greatest mental strength without running the risk of liability to mental disease must be one of the essential problems of the future for the educationist, the sociologist, the politician, and the physician. Insanity is commonly the final breakdown which shows that many previous generations had broken the laws of nature in their lives. It is the outcome of a civilisation in which the true principles of evolution for human beings had not been understood and assisted.

The chief modern authorities are: Blandford's *Insanity*; Bucknill and Hack Tuke's *Psychological Medicine*; Conston's *Mental Diseases*; Griesinger's *Mental Pathology*; Bovan Lewis's *Mental Diseases*; Maudsley's *Pathology of Mind*; Sankey's *Mental Disease*; Savage's *Insanity*; Spitzka's *Insanity*; Ball's *Mabules Mentales*; Esquirol's *Mabules Mentales*; Guislani's *Psychopathies*; Lay's *Mabules Mentales*; Morel's *Mabules Mentales*; Von Krafft-Ebing's *Psychiatrie*; Kraepelin's *Psychiatrie*; V. Ziemssen and Schulz's *Psychiatrie*.

Inscriptions is the name given to records, not of the nature of a book, which are engraved or inscribed on stone, metal, clay, and similar materials. Since ancient documents committed to such destructible materials as papyrus, parchment, or paper have largely perished, inscriptions on harder materials are in many cases the sole sources of our knowledge of ancient history and of early languages; and, even when MSS. have been preserved by copyists, inscriptions, which preserve the original forms of the letters, are of supreme palaeographical importance. All the books of the Phœnicians, Sabæans, Etruscans, Babylonians, Assyrians, Numidians, and Iberians have perished, and hence a considerable portion of our knowledge of early oriental history is derived solely from inscriptions. A very large number of inscriptions are mortuary epitaphs. Others, usually the most important, are records of the events in the reigns of kings. Others are dedications of altars, temples, or aqueducts. Many are of a religious character, recording donations to temples or in honour of the gods. Others are commercial contracts, banking records, receipts for taxes scratched on potsherds, scribbings on walls (*graffiti*), imprecations, and inscriptions on seals, gems, or vases. Probably more than 150,000 inscriptions are known, and a vast literature has accumulated around them. They are, however, usually classed, not by their subjects, but according to the language in which they are written, with a subsidiary chronological arrangement. The chief classes are Semitic, Greek, Latin, Runic, Cuneiform, Egyptian, and Indian.

Semitic Inscriptions.—The oldest inscription in the Phœnician alphabet is the dedication of a bronze vessel, found in Cyprus, which belonged to the temple of Baal Lebanon, and is now in the Bibliothèque Nationale at Paris. It was written in the reign of Hiram, King of the Sidonians, and may be assigned to the end of the 11th century B.C. or the beginning of the 10th. Of somewhat later date, about 800 B.C., is the Moabite Stone, which contains a record of the chief events in the reign of Mesha, king of Moab, including his war with

Ahab. It is now in the museum of the Louvre at Paris. In the same collection is a long inscription on the black basalt sarcophagus of Eshmunazar, King of Sidon, assigned to the close of the 5th century B.C. Among other important Phœnician inscriptions are a sacrificial tariff found at Marseilles; an 8th-century inscription from Nora, in Sardinia; the dedication of a bronze altar by Yehaumelek, King of Gebal; and numerous inscriptions of the Phœnician Kings of Cyprus, one of them a bilingual, which gave the key to the Cypriote writing (see PHOENICIA). In the same Phœnician alphabet is the Hebrew record in the tunnel which brought the water under Ophel to the pool of Siloam. It is assigned to the reign either of Hezekiah or Manasseh in the 7th century B.C. We have also a fragment of an inscription from Herod's temple at Jerusalem, and others from tombs near Jerusalem, which are earlier than the siege by Titus, and numerous early inscriptions from Jewish cemeteries in the Crimea, at Aden, Venosa, Arles, Tortosa, and Rome. At Palmyra there are more than a hundred inscriptions dating from the 1st to the 3d century A.D., but mostly written in the reign of Zenobia, and there are others in many of the museums of Europe. A Palmyrene inscription was found in 1878 at South Shields near the Roman wall. See PALMYRA.

At Nablis there is a Samaritan inscription, written in the reign of Justinian, containing a version of the Decalogue. The most interesting Arabic inscription is one in Kufic characters inscribed with gold letters on blue-glazed tiles running round the Qubbet es Sakra, or Dome of the Rock, at Jerusalem, the great mosque erected by the Calif Abdalmalik in the year 72 A.H. The Nabathean, or early Arabic alphabet, is used in numerous inscriptions on the rocks at Sinai, and also in the Hauran, one of which dates from the reign of Herod the Great. From the neighbourhood of Aden come a large number of inscriptions in the South Semitic alphabet; and there are two early Ethiopic inscriptions dating from the 4th and 5th centuries A.D. at Axum, in Abyssinia. At Hajjiabad and Nakhsh-i-Rustan, near Persepolis, are a number of inscriptions of the Parthian and Sassanian Kings. In one of them Sapor I. records his victory over the Emperor Valerian and the Roman army. These inscriptions are written in a script derived from the Aramean, and exhibit the oldest form of the Pehlvi alphabet. At Singan-fu, in China, is an inscription written partly in Syriac characters and partly in Chinese, dated in the year 781 A.D., and recording the introduction of Christianity into China by the Nestorian missionaries.

The *Corpus Inscriptionum Semiticarum*, a splendid and exhaustive work begun in 1881 by the French Academy under the editorship of M. Renan, will, when complete, include all the Semitic inscriptions in photographic fac simile. The most generally useful book dealing with Semitic inscriptions is Schneider's *Die Phœnizische Sprache* (1869), which contains 225 of the most important. Others will be found in Gesenius, *Monumenta Lingua Phœnicia* (1821), and in the *Corpus Inscriptionum Hebraicarum*. See PHOENICIA, MOABITE STONE.

Greek Inscriptions.—The oldest Greek inscriptions hitherto discovered are the mortuary records from the island of Santorin (Thera) in the Aegean, which may belong to the 8th and 9th, or even to the 10th, century B.C. The earliest inscriptions to which a definite date can be assigned are the records on the knee of one of the colossal statues at Abu Simbel, near the second cataract of the Nile, by Greek mercenaries in the service of Psammetichus, King of Egypt. They date from the end of the 7th or the beginning of the 6th century

B.C. These are followed by the records on the bases of the statues which lined the Sacred Way leading to the temple of Apollo, at Branchidae, near Miletus. They are all earlier than the Persian war, and are assigned to the 6th century B.C. Of about the same date is the celebrated Sigeian inscription from the Troad, now in the British Museum. Of the 5th century is the long and important inscription of Lygdamis, found by Sir C. Newton at Halicarnassus, which belongs to the time of Herodotus. After the Persian war Greek inscriptions became more numerous. The most interesting, from an historical point of view, is that inscribed on the trophy erected at Delphi by the Greeks to commemorate the defeat of the Persians at Plataea. It is now in the Hippodrome at Constantinople, where it was placed by Constantine. Another inscription of historical interest is the dedication to the Olympian Zeus of a bronze helmet, which formed part of the spoils taken at the battle of Cume in 474 B.C., when the naval power of the Etruscans was shattered by Hiero I., king of Syracuse. It was found at Olympia by Sir W. Gell, and is now in the British Museum (see ETRURIA). It was the practice of the Greek states to affix copies of treaties to the walls of their temples. Several of these have been preserved. They are mostly between Athens and her allies, and belong to the 5th and following centuries. The earliest which we possess is a treaty between the Eleans and the Heraeans, which is assigned to the middle of the 6th century B.C. It is engraved on a bronze tablet which was hung in the temple of Zeus at Olympia, and is now in the British Museum. To the 5th century belong the interesting records of the battles fought by the Athenians at Drabescus and Potidaea; also a list, now in the Louvre, of the Athenian citizens who fell in Cyprus and Egypt in the year 460 B.C.; several enumerations of the treasures deposited in the Parthenon; and detailed accounts relating to the erection and cost of the Erechtheum at Athens. The foregoing are the most important Greek inscriptions of the early period. Those of later date are extremely numerous. One of the most interesting, written in Greek hexameters, was discovered in 1879 at Brough in Westmorland. It is in memory of a Syrian youth who is believed to have perished during the campaign of Septimius Severus against the Caledonians in the year 209 A.D. It is now in the Fitzwilliam Museum at Cambridge.

It is estimated that 20,000 Greek inscriptions are known to scholars. More than 10,000 have been published by the Berlin Academy in the *Corpus Inscriptionum Graecarum*, of which the first two volumes, edited by Boeckh, appeared in 1828 and 1833; the third, edited by Franz, in 1853; and the fourth, edited by Kirchhoff, in 1856. Kirchhoff, Kohler, and Dittenberger have edited the *Corpus Inscriptionum Atticarum*, of which the first volume appeared in 1873. The chief historical inscriptions have been published in a handy volume by the Clarendon Press at Oxford, edited by E. L. Hicks, under the title *A Manual of Greek Historical Inscriptions* (1882). The dialect inscriptions are given in Cauer's *Dialects*, and fac-similes of the inscriptions most valuable for paleographical purposes by Rohl's *Inscriptiones Graecae Antiquissimae* (Berlin, 1882). For the beginner in Greek epigraphy, Rohl's *Inschriften Inscriptionum Graecarum* (Berlin, 1883), a cheap and useful little book, and Reinach's *Traité d'Épigraphie Grecque* (Paris, 1885) can be recommended; see also E. S. Roberts, *An Introduction to Greek Epigraphy* (Camb. Univ. Press, 1888). See table at ALPHABET, Vol. I, p. 187.

From Cyprus we have a number of Greek inscriptions in a very ancient pre-alphabetic character, which is usually designated as the Cypriote syllabary, and is believed to be related to the scripts of Asia Minor and Northern Syria, such as the Carian, the Lycian, and the Hittite, which are

known to us only through inscriptions. The most important of these is a long Lycian inscription assigned to the 5th century B.C., found by Sir C. Fellows at Xanthus, which is now in the British Museum. A number of Carian inscriptions, usually recording the visits of travellers, have been found in Egypt, chiefly at Abydos and Abu-Simbel. The Hittite inscriptions, which are written in a hieroglyphic character not yet deciphered, are engraved in Wright's *Empire of the Hittites* (1884). The Vannic inscriptions from Armenia are written in a form of the cuneiform character. See HITTITES.

Latin Inscriptions.—Between 60,000 and 70,000 Latin inscriptions are known. The oldest probably date only from the 3d century B.C. Of the early inscriptions those from the tombs of the Scipios, now in the Vatican Library, are of extreme interest. These, together with several of the oldest Latin inscriptions, are printed in the second appendix to Roby's *Latin Grammar* (1872), and are engraved in fac-simile in Ritschl's *Præter Latinitatis Monumenta* (1862).

Latin inscriptions are couched in a style of their own, consisting of regular epigraphic formulae, with conventional modes of expressing names, paternity, tribe, country, domicile, illegitimacy, adoption, naturalisation, and with abbreviated designations of status for freemen, freedmen, slaves, children, as well as of dignities and functions of all kinds in all the various grades of official life, military, civil, and sacerdotal. There are also conventional formulae for epitaphs; and others are employed for edicts, dedications to the gods, inscriptions on buildings, temples, aqueducts, and statues, as well as *sarcæ*, execrations, and theatrical *tesaura*. Besides formal inscriptions there are numerous *graffiti* scribbled on walls, such as those found at Pompeii, which have a literature of their own. As a specimen of the way of interpreting an ordinary Latin inscription, we may take the first three lines of No. 4114 in the *Corpus Inscriptionum Latinarum*. It begins thus: 'TIB. CL. CANDIDO, COS. XVIR. S. F. LEG. AUGG. PR. PR. PROVINC. IL. C.' &c. These abbreviations are to be expanded as follows: *Tiberio Claudio Candido Consuli, Quindecimviro sacris faciendis, Legato Augustorum duorum, propretore Provinciae Hispaniae Citerioris, &c.* Mortuary inscriptions, which are extremely numerous, usually begin with some stock formula, such as D. M. S. (*Dis Manibus Sacrum*) or H. S. E. (*Hic sepultus est*), and end with a prayer or pious wish, such as O. S. T. T. L. (*Opto sit tibi terra levis*). The Engubine Tables (q.v.) form the chief monument of the Umbrian dialect. There are about 5000 Etruscan inscriptions, which have an extensive literature of their own. See ETRURIA.

A complete collection of Latin inscriptions has been undertaken by the Berlin Academy, with the title *Corpus Inscriptionum Latinarum*, under the editorship of Mommsen, Hübnér, and others. Begun in 1863, this great work already extends to 15 quarto volumes, without reckoning supplements. The best book for a beginner is W. M. Lindsay's *Handbook of Latin Inscriptions* (1898) or Cagnat's *Cours d'Épigraphie Latine* (Paris, 1889). The most complete collection of the dialect inscriptions of Italy—Etruscan, Umbrian, Oscan, and Menapien—is Fabretti's *Corpus Inscriptionum Italicarum* (2 vols. 1867-77), with several supplements. *Die Umbrischen Sprachdenkmäler*, edited by Aufrecht and Kirchhoff (2 vols. 1849-51), and Mommsen's *Die Unteritalischen Dialecten* (1850) may also be consulted. The inscriptions in the Catacombs will be found in De Rossi's *Inscriptiones Christianae veteris Romae*. See LATIN, GRAFFITI.

Runic Inscriptions have been found in great numbers in Sweden, Norway, Denmark, Yorkshire, Cumberland, Kent, and the Isle of Man. Among the oldest is one assigned to the 1st century A.D. on a rock near Trondhjem in Norway; and the Tune Stone, also in Norway, which is assigned

to the 3d century. One of the most interesting is on a massive golden torque found at Buzen in Wallachia. This is a relic of the invasion of the Danubian provinces by the Goths in the 3d century. At Collingham, in Yorkshire, is a Runic inscription in memory of King Oswin, who was murdered in 650 A.D., and there is another at Bewcastle in memory of King Alfrith, who died in 670. At Barnspike, in Cumberland, there is a rock with a long inscription recording the treacherous slaughter by Robert de Vaux, a Norman knight, of Gillhies Bueth, owner of the lands of Lanercoast. The cross at Ruthwell (q.v.), near Dumfries, contains a portion of Cadmon's poem on the crucifixion.

The best collection of Runic inscriptions is by G. Stephens, *The Old Northern Runic Monuments of Scandinavia and England* (3 vols. 1866-84). A selection of the more important will be found in the *Handbook of the Old Northern Runic Monuments* (1884, by the same editor. See RUNES, OGAMS, SCULPTURED STONES.

American Inscriptions.—In Greenland, on the shores of Ballin Bay and Davis Strait, a few genuine Runic inscriptions have been discovered. They probably date from the 11th and 12th centuries, and were doubtless executed by Icelandic colonists or explorers. Records, variously conjectured to be Runic, Punie, Celtiberic, or Numidian, have also been found in the United States, notably on the Dighton Rock in Massachusetts, in the island of Mombegun off the coast of Maine, in the Grave Creek Mound in Virginia, and elsewhere. They prove, however, on examination, to be either natural markings on the rock, or the half-effaced pictorial records of Red Indian tribes, or even inscriptions by early European colonists. Very different are the numerous inscriptions on the walls of the palaces and temples in the ruined cities of Yucatan, Honduras, Mexico, and Guatemala. They are written in unknown characters, which appear to constitute a system of hieroglyphic or pictorial writing, akin probably to that of the Aztec MSS., which as yet have been only imperfectly deciphered.

The *Cuneiform Inscriptions*, from which the contemporary annals of Babylonia and Assyria have been deciphered in recent years, form by themselves a vast department of study. The oldest may date from about 3000 B.C. One of the most notable is the great historical inscription of Darius Hystaspes, engraved on the perpendicular face of a rock, 400 feet above the plain, at Behistun, in Persia. It contains a thousand lines of writing, in three languages, Persian, Proto-Medic, and Semitic Babylonian. Not only is it of immense historical importance, giving an authentic record of the events of the reign of Darius, but it is of great interest as having furnished the clue by which the cuneiform writing was first deciphered. Among other cuneiform inscriptions may be enumerated the annals of Sargon from Khorsabad; the account of the campaigns of Sennacherib, engraved on a colossal bull at Koumjik; the inscription of Samas-Rimmon, son of Shalmaneser, a contemporary of Ahab and Jehu; his inscription of Shalmaneser II., giving an account of the capture of Damascus; the long historical inscriptions of Tiglath-pileser I., of Sargon I., and of Esarhaddon, and the account of the Egyptian campaign of Assurbanipal, besides the inscription of Khammurabi, king of Babylon, which is older than the Exodus, of Uruk, of Naram Sin, of Nebuchadnezzar, of Nabonidus, his successor, and the extremely interesting inscription on the tomb of Cyrus. See ASSYRIA, BABYLONIA, BEHISTUN, CUNEIFORM.

The chief collection of cuneiform inscriptions is *The Cuneiform Inscriptions of Western Asia* (5 vols. folio, 1861-70), edited by Sir H. Rawlinson and E. Norris. Many of the most interesting of the cuneiform and

Egyptian inscriptions are translated in the more accessible volumes of the *Records of the Past*.

Egyptian Inscriptions.—The oldest Egyptian inscription to which a date can be assigned is one of Sent, a king of the second dynasty, who is believed by Mariette to have lived about 4700 B.C. This venerable record is now among the treasures of the Ashmolean Museum at Oxford. The historical inscriptions of the 18th and 19th dynasties are the most numerous and interesting. The records of the Asiatic campaigns of Thothmes I. and Thothmes III., of Seti I. and Rameses II., are all at Thebes. They are older than the Exodus, and constitute the chief materials from which the history of ancient Egypt has been reconstructed. Two of the faces of the obelisk called Cleopatra's Needle, now on the Thames Embankment, bear the name of Thothmes III., who first erected it; on the other two sides Rameses II. has caused his own name to be inscribed. On the wall of a temple at Karnak we have an account of Shishak's invasion of Judaea in the reign of Rehoboam. One of the latest of the Egyptian inscriptions is the Rosetta Stone, a trilingual record in Greek, hieroglyphic, and hieratic characters, engraved on a block of basalt. Its interest arises from the fact of its having afforded the clue which enabled Young and Champollion to decipher the Egyptian writing. See EGYPT, HIEROGLYPHICS.

Indian Inscriptions are extremely numerous. Many of them are grants to temples, engraved on copper plates. The oldest and most interesting are the edicts of Asoka, the great Buddhist king, who reigned over Northern India soon after the invasion of Alexander. There are seventeen versions of these edicts, two engraved on pillars at Delhi and Allahabad, and the rest on rocks in various parts of Northern India, from Orissa in the east to Gujarat in the west. Of later date are the inscriptions in caves, topes, and temples. There are also old Pali inscriptions in Burma, Java, and Ceylon.

The best collections of Indian inscriptions are in the *Corpus Inscriptionum Indicarum*, edited by Cunningham (1877); the *Archæological Survey of Western India*, edited by Burgess (1874-78); the *Elements of South Indian Palæography*, by Burnell (1878); and Muller's *Ancient Inscriptions in Ceylon* (1883). The best guide to Indian palæography is Holle's *Tabl. van Oud en Nieuw Indische Alphabeten* (Batavia, 1882).

See ALPHABET, WRITING, PALÆOGRAPHY, NUMISMATICS. Accounts of most of the foregoing inscriptions will be found in *The Alphabet*, by Canon Taylor (1883).

Insectivora (Lat., 'insect-eating'), an order of mammals, the members of which—shrews, moles, hedgehogs, and the like—are mostly terrestrial, usually nocturnal in habit, and small in size. They feed mainly on insects and small animals, and in adaptation to this diet, which often plays a useful part in the economy of nature, the summits of the molar teeth are beset with small conical tubercles. A few, such as the moles, burrow; a few—e.g. Potamogale—are aquatic; while the divergent Galeopithecus, if included in this order, has among its peculiarities that of gliding through the air (see FLYING ANIMALS). The majority, however, have the general habit of shrews. Though often externally resembling various rodents, the Insectivora are entirely distinct in their anatomy. Altogether over two hundred living species are known, and many fossils, especially from Tertiary strata. The Insectivora are themselves lowly mammals, but lead on to Bats.

See HEDGEHOG, MAMMALIA, MOLE, SHREW; Dobson, *Monograph of the Insectivora* (Lond. 1882); Th. Gill, *Synopsis of Insectivorous Mammals; Bull. Geol. and Geog. Survey, U.S.A.* (Washington, 1875).

Insectivorous Plants. There are several hundred species of Dicotyledons which in some

way or other catch insects and use them for food, either digesting their bodies or simply absorbing the products of their decomposition. They are remarkable for the adaptations of structure and function by which the insects or other small animals are secured, and for their obvious approach to the animal mode of nutrition. For it is a familiar fact that all typical plants feed at what may be called a very low chemical level, obtaining the required carbon from the carbonic acid gas of the air, and the equally essential nitrogen from ammonia, nitrates, and the like in rain-water and soil; while animals, on the other hand, do not derive their carbon from simpler substances than starch, sugar, and fat, nor their nitrogen from a lower source than the albumens manufactured by other animals or by plants. The insectivorous forms, however, break down the distinction in so far as they feed like animals on substances at a high chemical level; and the unity becomes more striking as we recognise that many of the insectivorous plants exhibit marked sensitiveness, mobility, and digestive power.

Altogether there are nearly five hundred species of insectivorous plants, referable to about twelve genera, and to half a dozen Dicotyledonous orders. They are represented in every great geographical region, perhaps with the exception of the African wastes and the Argentine pampas. For convenience of treatment we follow Kerner in recognising three sets: (1) those with pits or cavities, into which small animals enter, but from which they are unable to return—e.g. Bladderworts and Pitcher-plants; (2) those in which the insect-catching depends wholly on the viscidness of the leaves—e.g. *Drosophyllum*; (3) those which exhibit distinct movements which help to secure the insects—e.g. Sundew and Fly-trap.

1. *With Pit-like Traps.*—The Common Bladderwort (*Utricularia vulgaris*,

Fig. 1.—*Utricularia Graefiana*:
a, section of bladder of *Utricularia
nepifolia*.

ord. Lentibulariaceae or Utriculariaceae) is a rootless floating water-plant, not uncommon on tarns and marshy lochs, but by no means conspicuous except in summer, when its handsome golden blossoms are raised on a flower-stalk about six inches above the water. Among the slender leaves borne on the straggling floating stem are numerous bladders, to which the plant owes its name. They are much modified dimpled leaf-organs, and form a simple but effective trap. As the figure shows, they are hollow chambers, entered by a door or valve which opens inwards only, and allows of no egress. Tiny crustaceans, known as water-fleas, whether chased by their enemies, attracted by a slight mucilage, or prompted by fatal curiosity, clamber on the antenna-like bristles which project from and perhaps protect the bladders. So far they are safe enough, but if they push their way through the narrow door, they find within the bladder a prison and a tomb. Escape is impossible, death ensues, and the products of decomposition are absorbed by suck-

ing cells (fourfold hairs) on the walls of the bladder. Towards the end of summer, when the water no longer swarms with crustaceans, the *Utricularia* begins to die off, the life is concentrated in terminal buds, the bladders fill with water, and the plant sinks to the bottom. Thence it rises again in spring with a fresh equipment of buoyant bladders. There are numerous species of *Utricularia*, of which several are aquatic like the above; while others, especially in the tropics, are terrestrial. The booty of course changes with the situation, but the general habit seems to be the same throughout. We can only mention an allied genus, *Genlisea*, which has traps of a different pattern, approaching those of the pitcher-plants.

Among the *pitcher-plants*, the most familiar belong to the genus *Nepenthes* (ord. *Nepenthaceae*), which includes nearly forty species, widely distributed by swamps and jungle pools, 'from New Caledonia and New Guinea over tropical Australia to the Seychelles and Madagascar, over the Sunda Islands and Philippines to Ceylon, Bengal, and Cochin-China.' The young plant has a rosette of half-prostrate leaves, quite unlike those of the adult, with a terminal hooked crest overhanging a slightly hollowed broad lower portion. A stem shoots up, however, bearing other leaves, broad and spatulate in form, ending in a cylindrical tendril, which twists round adjacent branches and develops terminally into a large cavity or pitcher. The tendrils gradually lift the stem, and over the pool there eventually hang dozens of pitchers. These vary in size from a couple of inches to about a foot,

Fig. 2.—Pitcher-plants:

A, *Nepenthes Phyllanthiflora*; B, *Sarracenia purpurea*;
C, *Darlingtonia californica*.

are usually brightly coloured with red, yellow, and purplish blotches, and bear two lateral flanges and a terminal lid, which opens when the pitcher attains its full size. Partly by the colour and partly by the honey glands of the lid and pitcher margin, insects are attracted; they sip the sweet secretion and venture farther down, only to land on an exceedingly smooth, waxed, slippery 'conducting surface,' whence they fall into the lower third or half of the pitcher, which contains water and digestive secretion. When an insect falls, the secretion is stimulated and becomes acid. As analysis has shown the presence not only of various acids (malic, citronic, formic) but also of a peptic ferment, the fluid is exactly like that of an animal stomach, and the result is the same.

Another well-known pitcher-plant is *Sarracenia purpurea* (ord. Sarraceniaceae), widely distributed in swampy regions of eastern North America from Hudson Bay to Florida. A rosette of half-prostrate hollow leaves surrounds an erect flower-stalk. The pitchers are topped by a crest, which is decorated with reddish streaks, and disposed so that it catches rain-drops and lets them slide into the pitcher. Insects are attracted by the sweet secretion of glandular hairs on the lid or crest, wander farther down on a so-called 'conducting surface,' covered with downward-pointed hairs which forbid return, and eventually fall hopelessly into the water occupying the lower part of the pitcher. There they are decomposed and absorbed. Several inches of half-rotten insects are found at the base, rendering the water brown and putrid, and emitting a disagreeable smell. That digestion does not occur seems certain, and the fact is confirmed by Riley's observation that two insects—a fly (*Sarcophaga sarraceniae*) and one of the Lepidoptera (*Xanthoptera scariovoca*)—brave the horrors of the trap in safety, and utilise the dungheap of rotten insects as a suitable place wherein to deposit eggs. The grubs, which would perish if digestion occurred, thrive well and eventually bore their way through the sides of the leaf. Birds occasionally discover the store of insects and rifle the pitchers with their beaks. While all the species of *Sarracenia* probably agree in being non-digestive, they present considerable differences of structure, which we cannot here describe. Beside the above species—*S. purpurea*—may be ranked *Heliamphora nutans* (from Mount Roraima in British Guiana). In *S. carolinensis* and in *Darlingtonia californica* (from the Sierra Nevada) the pitcher is capped by a helmet, so that no water can enter; the contained liquid must therefore be wholly a secretion, though still only putrefactive. Finally, *S. drummondii* and *S. undulata* are in external form almost nearer to *Nepenthes* and *Cephalotus* than to the other species of *Sarracenia*.

In the two species of *Sarracenia* last mentioned only some of the leaves are modified into pitchers, the others remaining green, lance-shaped, and unhollowed. So is it with *Cephalotus follicularis* (Cephalotaceae, near ord. Ribesiaceae), which is restricted to a limited area near Albany in Western Australia. Here in the usual basal rosette only the lower leaves are pitchers, two inches or so in height, best adapted for catching ants and ground-loving insects. The outer surface bears ridges which help the insects up, and there are the usual attractions of bright colour and sweet secretion. Intoxicated, it may be, with the honey, or merely inquisitive and unwary, the visitors pass from the sides or from the half-open lid to the slippery though corrugated

Fig. 3.—Pitcher of *Cephalotus follicularis*.

margin, and thence fall into the liquid which fills half the pitcher. Endeavours to return are balked by a projecting shelf, by an area beset with stiff downward-pointed papillae, and by sharp spines round about the intumed margin of the collar. As the glandular secretion has an acid reaction and a solvent power, *Cephalotus* is also to be credited with true digestion.

In regard to the morphology of the pitchers, we shall simply cite the recent conclusions of Macfarlane: (1) The leaf in *Nepenthes*, *Heliamphora*, *Sarracenia*, and *Darlingtonia* is compound, and consists of from two to five pairs of leaflets; (2) there is a marked tendency to dorsal fusion of the leaflets from apex to base; (3) such fused leaflets

are seen in the broad basal part of *Nepenthes* leaf, and in the flaps and lids of the various pitchers; (4) the pitcher itself is a deep dorsal involution of the midrib just above the termination of the fused upper pair of leaflets, except in *Cephalotus*, where, as Dickson clearly showed, it is an involution of the leaf-blade.

Very different from the pitcher-plants, and with appliances less involved for insect-catching, is the Toothwort (*Lathraea squamaria*, ord. Scrophulariaceae), a pale, chlorophyll-less parasite found in British woods, battening on the roots of trees and shrubs. Excepting the flower-stalk, the stem is virtually underground; it bears stertorial roots and tooth-like leaves. The latter are hollow, and are entered through a narrow aperture by many kinds of small animals. These seem to be entangled in proteoplasmic exudations within the leaf-cavity, find exit impossible, die, decompose, and are absorbed. Along with the toothwort ought also to be ranked *Bartsia alpina*, whose underground buds show a somewhat similar structure and carnivorous habit.

2. *Plants which catch Insects by Viscid Secretion without Pits or Movement.*—The best representative of this set is *Drosophyllum unguiculatum* (ord. Droseraceae), a native of Portugal and Morocco, growing with luxuriance in sandy or rocky places, to a height of about a span. The long linear leaves are richly beset with glands, many borne on long stalks, red in colour, and copious in an acid, viscid, dewdrop-like secretion, the others invisible to the naked eye, without stalks, colourless, and with an acid, dissolvent secretion, which is only exuded in response to the stimulus of some nitrogenous substance. Insects of various kinds alight on the long leaves, knock off the drops from the stalked glands, move anxiously about knocking off more and more until they are thoroughly besmeared, and their tracheae choked. Giving up the struggle, they sink on to the surface of the leaf, where the sessile glands begin the dissolvent and absorbent process. Kerner notes that the peasants about Oporto use the *Drosophyllum* in their dwellings as a convenient substitute for fly-paper.

3. *Plants which exhibit Distinct Movements in their Insect-catching.*—The Common Butterwort (*Pinguicula vulgaris*), belonging to the same order as *Utricularia*, is a widely distributed representative of a genus including about forty species, all growing on more or less marshy ground (see fig. at BUTTERWORT). From a rosette of plump glistening leaves there rises for several inches an upright stalk, bearing a beautiful two-lipped, spurred flower of a violet colour. The leaves have a distinct fungus-like odour, doubtless attractive, and are covered with glands, some stalked like miniature mushrooms, others almost sessile, both with a copious, viscid, acid secretion. This serves as 'insect-lime,' but, besides retaining the unwary midges, it finally digests them. Drops of rain may fall on the leaves, or pebbles may land there, but without noteworthy effect; a small insect, however, stimulates a copious flow of the fatal secretion. But there is also movement: for, when an insect is caught, the margins of the leaves slowly curl inwards for an hour or two, thus surrounding the booty, or shifting it nearer the centre, in any case exposing it to more glands. After digestion, the results and the surplus exudation are absorbed, leaving finally the undigested skin of the insect on the more or less dry leaf surface. More than 150 years ago Linnæus noted how the Lapps used the butterwort for curdling milk, a property due to a rennet-like ferment which the plant has in addition to the digestive or peptic. The antiseptic qualities of the ferments perhaps

justify another old custom of applying the leaves to the sores of cattle.

Beside the butterwort on the marshy moor we are likely to find *Deosera rotundifolia* (ord. Droseraceae) or some other species of sundew. Again, we have a rosette of prostrate leaves, from amid which rises a stalk with inconspicuous whitish flowers. Very striking, and constant in the forty or so species, are the red glandular 'hairs,' 'tentacles,' or processes which grow at different lengths from the upper surface and margins of the leaf. These are complex little structures with a head of glandular cells, supplied by numerous water-pipes (wood-cells or tracheides), and surrounded externally by a drop of viscid secretion. These tentacles are sensitive, mobile, secretory, digestive, and absorptive. To drops of rain they are indifferent, to irritant particles they may respond by increased secretion; but when a midge or a small particle of nitrogenous food is placed upon them, they become marvellously though by no means rapidly active. A living midge, which mistakes the secretion drops for nectar, lights on the leaf, and is forthwith entangled; as it struggles it becomes more hopelessly besmeared, and meanwhile the secretion becomes

Fig. 4.—Leaf of *Deosera rotundifolia* seen from above.

truly digestive or peptic. More than that, however, the 'tentacles' curve down upon the victim, first one, and then, after an interval of ten minutes, another, till all the two hundred or perhaps half of them close upon the dying midge. The whole leaf may become concave if the booty is large, and then, after an hour or two of leisurely bending, the leaf looks like a closed fist. Many kinds of insects are thus caught, and even a dragon-fly may fall victim to the combined efforts of several adjacent leaves. The sensitiveness is finer than our most delicate nerves or balances, for a sundew hair will respond to a millionth of a grain of stimulating nitrogenous matter. The response is marked by the increased secretion and by the bending, while internal changes are traceable under the microscope passing from one cell to another down the tentacle. As one leaf may be seen with the remains of a dozen insects, and as there are half a dozen or so well-formed leaves, the carnivorous diet of the sundew is often considerable, and it has been demonstrated that the yield of seeds is better in those which are able to gratify their natural appetite.

Venus's Fly trap (*Dionaea muscipula*), which Linnaeus called the miracle of nature, is in several ways a more elaborate insectivorous plant than any of the above, and is the climax of the order Droseraceae. A native of the east of North America, with very local distribution, from Long Island to Florida, it grows on moorland, with a circle of more or less prostrate leaves round the base of a many-flowered stalk, which rises 4-6 inches from the ground. The leaves, about 4 inches in length, consist of a spatulate stalk, which is constricted to the midrib at its junction with the broad blade. The halves of the blade are movable on one another along the midrib, and close together as this volume would do if fitted with an automatic closing spring. Round each margin are twelve to twenty long teeth, which interlock in rat-trap fashion with those

of the opposite side; the centre of the leaf bears numerous rosy digestive glands; and there are on each half of the blade three sensitive hairs, which rise obliquely, but bend flat on a basal joint when the leaf closes. The blade shuts up in 8 to 10 seconds

when one of the sensitive hairs is stimulated, and if an insect is caught in the trap a profuse secretion is exuded from the glands. Digestion goes on for a week or a fortnight according to the size of the booty; finally the digested material and the secretion are absorbed, and the leaf then reopens. There is evidently division

Fig. 5.—*Dionaea muscipula*: a, leaf.

of labour to a greater extent than in the sundew, for the marginal teeth, the sensitive hairs, and digestive glands have separate functions. The delicacy of sensitiveness, the rapidity of movement, and the copiousness of the digestive secretion are noteworthy, while it is also significant that Barton Sanderson has detected electric currents similar to those observed in the neuro-muscular activity of animals.

Superficially somewhat like the bladderwort, in its leaf-structure very like *Dionaea*, is an aquatic plant, *Aldrovanda vesiculosa* (ord. Droseraceae), at home in south and central Europe, flourishing in ponds and pools where clear water is warmed by the summer sun. A thin rootless floating stem bears whorls of peculiarly modified leaves, dies away at one end as it grows on the other, forms in autumn a concentrated terminal tuft, which sinks to the mud at bottom and hibernates. Thence it rises again in spring lightened of its stores of starch and with buoyant air-spaces. The leaves consist of a spatulate stalk and a broad blade, which folds along the midrib like that of the fly-trap. The margin is firm, with small teeth, which meet those of the opposite side when the leaf is closed; externally a few long bristles project; the surface bears numerous longish hairs and also small stellate structures; there are large and small glands. When the water-fleas, insect-larvæ, or even diatoms rest on the surface of the leaf, the half-blades close quickly as in the fly-trap, the victims are imprisoned, and, though they may remain alive for some days, there seems no doubt of their final absorption. Other species of *Aldrovanda* from Australia and Bengal seem to have the same habit.

Besides the true insect catchers noted above, there are not a few plants, e.g. among the Saxifragæ, Sedums, and Primulas, on the glandular surfaces of which insects are often entangled. These plants suggest how the insectivorous habit might begin, and there are two species in the sundew order, *Roridula dentata* and *Eublis gigantea*, in which the insect catching seems to be more than incipient. Among the possibly insectivorous forms we must also include a Brazilian fern, *Elyophoglossum glutinosum*, and several liverworts, e.g. *Ammonohelea mucosa* and *Phiscotum cochleariforme*. Zopf has recently described an interesting fungus (*Arthro-*

botrys oligospora) which catches small threadworms in great numbers in its nooses, riddles their bodies with a growth of fine threads (hyphae), and absorbs the tissues.

Utility.—The adaptations for catching and utilising insects are so numerous and effective, that we are apt to conclude too readily that the insectivorous habit is not only advantageous but necessary for the health of the plants. There are, however, several facts which suggest caution. Thus it has often been noticed that a leaf of sundew or fly-trap may suffer, and even die, from the effects of too big a meal, a serious enough objection to utility were the casualty not as rare in nature as it is common in experiment. More important is the difficulty raised by cultivators, who point to all sorts of insectivorous plants flourishing perfectly without any insect food. To this it can be retorted that the natural conditions of scanty nitrogenous supply are probably not observed in the greenhouse, but the facts force us to abandon belief in the necessity of the insectivorous habit. We can only maintain that it is normally advantageous, a conclusion confirmed in some cases by the decrease in the quantity and quality of the seeds when no insects are available. From this, however, we need not conclude that the insectivorous function is the complete or even the original function of any of the curious leaf-structures above described.

Physiological Summary.—(1) It is a familiar fact that sundew and butterwort generally grow among bog-moss on the moors, hardly rooted in the soil, and therefore less adapted than ordinary plants to suck up the all-important nitrogenous compounds. The same relative scantiness in nitrogenous supplies is more or less marked in the habitats of other insectivorous plants, and doubtless renders them more dependent on their peculiar animal diet. All are said to be averse to the presence of much lime. (2) The diet is to some extent a matter of chance; both creeping and flying insects, small flies and even large moths, besides spiders, and centipedes are caught by the terrestrial and pendent traps. The aquatic bladderwort's most frequent victims are the small crustaceans known as Cyprids; while the subterranean *Lathraea*'s prisoners vary from the rank of mites down to infusorians. (3) The attractions of insectivorous plants are manifold; a mushroom-like odour in the butterwort lures insects which frequent fungi, and some of the others also appeal to the sense of smell; the 'dew-drops' of *Drosera*, the rosy patch on the fly-trap, the bright colours of many pitchers are obvious enough charms; while the frequent exudation of honey is the most direct lure of all. (4) In *Nepenthes* and *Cephalotus*, *Drosera* and *Drosophyllum*, *Dionea* and *Pinguicula*, the bodies of the insects caught are digested, that is to say, chemically altered into soluble substances, which are absorbed by the cells of the leaf. The process agrees with animal digestion in the net result, and in the presence of a peptonising ferment and an acid. Too little is known about the ferment or ferments, and also about the various acids present; but there is no doubt in regard to their digestive activity. It is very important, however, to recognise, with Morren and others, that in plants digestion and the activity of ferments are by no means confined to the insectivorous forms. Thus the diastase which in germinating seeds, &c. turns starchy material into sugar is virtually the same as the ferment in the saliva, &c. of animals; similarly in both plants and animals there is an inverting ferment which turns cane-sugar into grape-sugar; there is also an emulsifying or saponifying ferment in plants, acting on fats and oils in a manner comparable to part of

the role of the pancreatic juice. J. R. Green has described a rennet-forming ferment, comparable to that of the calf's stomach, not only in *Pinguicula*, but in the flowers of *Galium verum*, in the stem of *Clematis vitalba*, in the petals of the artichoke, &c.; finally, a peptonising ferment has been detected not only in insectivorous plants, but in such diverse situations as the latex of *Carica papaya* and the seeds of *Vicia*. The protoplasmic changes of plants are comparable to those of animals not only fundamentally, but also in many details, and the insectivorous plants are not unique, but simply conspicuous illustrations of vegetable digestion. (5) There is no doubt that both the products of digestion and the results of decomposition are absorbed by the insectivorous plants. Large stomata, protruding papillae, suctorial 'hairs,' and other structures in the different plants are sometimes credited with this function, about which little definite information is yet forthcoming. An interesting, if hardly conclusive, corroboration of the absorbent activity is given by Clark, who fed *Drosera* with flies saturated in citrate of lithium, and some days later detected with the spectroscope the presence of the metal throughout the whole plant, in fact even in the flower. (6) The sensitiveness so marked in sundew and fly-trap is not of course unique, but is illustrated in the leaves, tendrils, stamens, stigmas, &c. of many plants, and may be compared—though we cannot go much further—with that of animals. Both *Drosera* and *Dionea* respond to various kinds of stimuli, but usually and most readily to that of nitrogenous substances. Darwin gives numerous illustrations of the sundew's sensitiveness to extremely homeopathic doses (0.000095 of a milligramme) of nitrate of ammonia and the like. In the fly-trap the sensitiveness, as we have seen, is definitely localised in the six jointed hairs. (7) The movements of sundew, fly-trap, and *Aldrovanda*, like those in the leaves of the sensitive plant or the stem of the hop, the stamens of the barberry or the stigma of *Mimulus*, are associated with changes in the cells of the plant. It is easy enough to compare the movements with those of contracting muscles; but we are still far from being able to work out the comparison or determine the divergence. Four points may be noticed: (a) In the tentacles of *Drosera* the movement is associated with a visible change in the contents of the cells. Darwin described this, perhaps mistakenly, as 'aggregation of the protoplasm,' and compared it with analogous changes seen elsewhere. From what we know of movement in other plants, it is likely that the activity of the insect-catchers is connected with a change in the water-tension or turgidity of the cells. (b) In the movement of *Dionea* Darwin detected a measurable contraction or alteration of form; the same has been seen by Cohn, Haeckel, and others in the mobile organs of other plants, and at once suggests the change of form in muscle fibres. (c) Though there is no trace of anything like the nerves of animals, there is no doubt that a stimulus provoking motion passes from cell to cell and from part to part in both sundew and fly-trap. (d) Finally, Burdon Sanderson has described a resting and an action current of electricity in *Dionea*, and concludes that 'the property by virtue of which the excitable structures of the leaf respond to stimulation is of the same nature as that possessed by the similarly endowed structures of animals.'

Although our knowledge of insectivorous plants dates from 1768, when Ellis sent to Linnaeus a description of the fly-trap and its habits, structural investigations prevailed until Darwin in 1860 began the thorough experimental study of insectivorous plants, comparing their sensitiveness,

mobility, and digestive powers with those of animals. Since then the physiological interest of these plants has been kept steadily in view, our analysis of their vital processes becoming with each year more complete. At the same time, the morphology, especially of the pitcher-plants, has been studied with great success. The most difficult question concerning the origin and evolution of the insect-catching structures and functions is still a problem of the future.

See the following general works from which a guide to the vast literature will be obtained: C. Darwin, *Insectivorous Plants* (1875); O. Drude, in Schenk's *Handbuch der Botanik* (vol. i, 1881); P. Geddes, article 'Insectivorous Plants,' *Encyclo. Brit.*; A. Kerner von Marilaun, *Pflanzenleben* (vol. i, 1887); J. Sachs, *Physiology of Plants*, trans. by Marshall Ward (1887); S. H. Vines, *Physiology of Plants* (1886).

Insect-powder is a greenish-yellow powder having a slightly pungent odour. When genuine it is prepared by powdering the closed flowers of various species of Pyrethrum, especially *P. caruncatum*, *P. roseum*, and *P. vincetoxicifolium*. When dusted on fleas and other insects it soon stupefies and finally kills them, but whether this is due to subtle emanations from the oil or to the contact with the powder is undetermined. It is generally stated that the volatile oil does not possess this action, but the writer has noticed that when midges alight on a hand which has previously been rubbed with an alcoholic tincture of the powder they become stupefied, and in many instances rapidly die. The powder is innocuous to man, although it is stated to cause partial confusion of ideas in those who sleep in a room in which much of it has been used.

Insects are numerically the largest class of animals, occupying among Invertebrates a position in many ways similar to that held by birds in the backbone series. Widely separated as birds and insects are in structural rank, they have many common characters: both are very rich in species, and exhibit marvellous variety within narrow range; both are capable of true flight, are on an average very active in habit, and abound in illustrations of gay colouring; both have highly developed sensory and nervous organs.

Like other Arthropoda (q.v.), insects have jointed bodies and limbs, an enveloping cuticle of Chitin (q.v.), a ventral chain of ganglia, and a dorsal brain. Like *Peripatus* (q.v.)—a survivor of the ancestral stock—and like the lower class of Myriopods, insects breathe by air tubes or tracheæ, and are therefore included under the title Tracheata. But, contrasted with *Peripatus* and Myriopods, insects have made two great steps of progress: the body is centralised, with locomotor limbs reduced to three pairs (whence the term Hexapoda), and all the typical average forms have wings. The concentration is seen in the reduced number of rings or body-segments, in the absence of developed appendages on the hind-body (or abdomen) of the adults, in the complexity of the mouth-appendages, and in the gathering together of the ventral nerve-centres. In many cases, however, the progress is emphasised only in the fully-formed insects, for the caterpillar in the absence of wings, with less compact nervous system, with more numerous and primitive appendages, &c., recapitulates an ancestral stage.

To sum up, insects are Arthropods, which are usually winged in adult life, breathe air by means of tracheæ, and have frequently a metamorphosis in their life-history. The adult body is divided into (1) a *head*, with three pairs of appendages (legs), plus a pair of pre-oral outgrowths, the antennæ or feelers; (2) a *thorax*, with three pairs of jointed legs, typically plus two pairs of dorsal,

compressed sacs—the wings; (3) an *abdomen*, without legs, except in so far as these are rudimentarily represented in stings, ovipositors, and the like. It is impossible at present to give any secure estimate of the number of insects, though it is probably safe to say that they exceed all other animals taken

Fig. 1.—Disarticulated Beetle:

together. Over 80,000 species of beetles or Coleoptera and about 15,000 moths and butterflies have been recorded; and Speyer estimates the total census at 200,000, while McLachlan concludes that future entomological industry will raise the sum total of insect species to a million.

Structure and Functions.—The anatomy and physiology of insects will be discussed together, and that as tersely as possible, referring to the articles ANT, BEE, BUTTERFLY, &c. for illustrations, and to the works cited for details.

Form.—The body of an insect consists of a distinct, undivided head, probably composed of four obscure segments, of a thorax with three divisions (pro-, meso-, and meta-thorax), and of an abdomen typically with eleven rings. In detail, however, the varieties are legion; thus, the thin waisted wasp contrasts with the cockroach, the lank gnat with the compact bug, the graceful May-flies with the somewhat ungainly locusts, the minute midges with the Goliath beetles, and humming-bird moths.

Appendages.—The jointed feelers or antennæ, which are outgrowths of the head, not strictly comparable to legs, have often numerous nerve endings, and seem to be used in smelling, as organs of touch and guidance, and also in caressing or in communicating impressions to friends. Exactly comparable with legs are the three pairs of mouth-appendages, projecting downwards or forwards from the head, to which they are jointed and from which they are worked by muscles. The first pair—the mandibles—have but one joint, and are without the lateral 'pulp' present in the crustacean organs of the same name. They are biting and chewing organs, and are more or less reduced in those insects which suck. Next come the first pair of maxillæ, which have jointed 'palps.' The second pair of maxillæ are united at their base, and form the so-called labium, also provided with palps. In the different orders, and in association with the

diverse diet, these three pairs of mouth-organs vary greatly, as may be seen by comparing those of cockroach, house-fly, moth, and bee. In connection with the three pairs of legs on the thorax, it is necessary in identifying insects from a manual to become familiar with the division of the limb into coxa, trochanter, femur, tibia, and tarsal joints,

Fig. 2.—Mouth parts of Cockroach (after Savigny):

a, labrum; b, mandibles; c, first pair of maxillæ, with d, stipes; e, lacinia; f, galea; g, maxillary palps; h, sub-mentum of second pair of maxillæ or labium; i, mentum; k, labial palps; l, paraglossa; m, lacinia, the last two together forming the ligula

are seen on that region in the adults. Such hints we find in the lowest wingless insects (Thysanura), and at least plausibly in stings and ovipositors.

Wings.—The adult insect usually bears two pairs of dorsal outgrowths or wings on the two posterior rings of the thorax. These are flattened sacs, really double, worked by muscles, traversed in various patterns by 'veins,' which include air-tubes, nerves, and vessel-like continuations of the body-cavity. They are undeveloped in some passive females, and are likewise absent from many parasitic forms, such as lice and fleas. In these cases the wings have been lost, while they have never been

Fig. 3.—Cross-section through the Thorax:

a, tergum; b, wing; c, epimeron or upper part of side; d, stigma or spiracle; e, epidermis or lower part of side; f, leg; g, sternum; h, nerve-cord; i, alimentary canal; l, trachea; l, heart

attained by the lowest insects—the Collembola and Thysanura. When at rest the wings are usually folded in various ways, but the dragon-flies and some others keep them expanded. The two pairs may be almost alike, as in bees and butterflies; those in front may be merely covers (*elytra*) for the hind pair, as in beetles, or contorted rudiments in the little bee-parasites (Strepsiptera); the hind pair may be linked to the fore pair, as in Hymenoptera, and are rudimentary 'balancers' or 'halteres' in flies. They are often hairy or scaly, or gorgeous with pigment, or occasionally odoriferous. Professor Eimer has shown that the colour-

ing and marking of butterfly wings serve as indices of the progress and relationship of species. As to their origin, it seems plausible to compare them to the tracheal outgrowths seen in some aquatic larvae, and to regard them as primarily respiratory and secondarily locomotor. One may venture to suggest that the additional respiratory efficiency derived from such outgrowths would increase the total activity of the insect, and more or less directly lift it into the air.

Locomotion.—Insects are emphatically locomotor animals. They walk, run, and jump with the quadrupeds; they fly with the birds; they glide with the serpents; and they swim with the fish. Even the limbless larvae of many forms move deftly, contracting their bodies, and utilising jaws, hairs, and tubercles to help them along. Some will even

Fig. 4.—Thorax and part of the Abdomen of an Ephemeroid Larva (from Lang, after Graber):

a, rudiments of posterior wing; b, c, d, tracheal gills; e, f, rudiments of anterior wings; g, longitudinal tracheæ; to show close analogy between wings and tracheal gills.

jump to a relatively enormous height of six inches or more, by taking their tails in their mouths and letting go suddenly. The limbed larvae, and especially the true caterpillars, often move with great rapidity; a few jump, and many climb; others utilise their silken threads in spider-like fashion; while the young dragon-flies propel themselves along by the forcible expulsion of water. Even some pupæ move about, but the triumphs of locomotion are seen in the adult insects. Reference must be made to such a work as the *Introduction* of Kirby and Spence, and recourse had to actual observation, if any adequate conception be desired of the variety of ways in which insects walk, run, climb, swim, burrow, and fly. In connection with the flight of insects it may be noticed that the movement of the wings does not essentially differ from that of birds, that motion in a vertical direction is particularly easy, that steering is more difficult, especially since the very lightness of the bodies of insects make them liable to be blown about by the wind. Marey calculates the approximate number of wing-strokes per second at 330 for the fly, 240 for the humble-bee, 190 for the hive-bee, 110 for the wasp, 28 for the dragon-fly, 9 for a butterfly (see FLYING).

Skin.—Insects resemble other Arthropods in having a firm chitinous cuticle formed from the epidermis or hypodermis (see CHITIN, CUTICLE). The cuticle bears scales, tubercles, and hairs, of which the last are sometimes olfactory or otherwise sensory. In spite of the ensheathing armature there are often glands in connection with the skin—witness the salivary glands opening near the mouth in almost all insects, the silk or spinning glands of many larvae, especially of such as make cocoons, the odoriferous glands of bugs and beetles, the poison-glands of the stinging ants, bees, and wasps, the wax-glands of some Aphides, Coccus insects, and bees. Before the full size is reached there are skin castings or moultings, often numerous. The muscular system is almost always highly developed. The muscles which work the legs and mouth-organs, raise and depress the wings, influence the income and expiration of air, control the circulation, and move the segments of the body on one another are most important. The nervous system consists, as in other Arthropods, of a complex dorsal brain or supra-oesophageal ganglionic centre, supplying eyes and feelers, and of a double

ventral chain of nerve-centres. From the first ventral (or sub-oesophageal) ganglia, connected with the brain by a ring round the gullet, the mouth-appendages are innervated. In many insects the ventral chain is centralised in a few ganglia, and is usually more concentrated in the adults than in the larvæ.

Sense-organs.—Except in fleas, lice, and the lowly Collembola, adult insects have compound eyes. These are often associated with simple eyes or ocelli, which are all that ever appear in larvæ or in the three sets of insects mentioned above. Blind insects also occur along with other blind animals in the darkness of caves. Auditory organs are represented in almost all orders by peculiar nerve-endings ('choriotalon' and 'tympalal' organs) superficially disposed on various parts of the body. On the tactile antennæ, and probably also on the maxillary palps of various insects, there are specially innervated skin cells and hairs believed to be olfactory in function; while others more within the mouth are erolited with gustatory sensitiveness. The skin of insects seems in certain regions to be sensitive to the differences of light and shade, so much so that some speak of a sixth or 'dermatoptic' sense. Much experiment and observation is still required on the senses of insects, and we can only mention such general facts as the following. There is sometimes both optic and auditory sensitiveness to impressions which are beyond the range of human sight and hearing; in flower-visiting and other insects there is abundant evidence of sensitiveness to fragrance and colouring, and smell probably aids greatly in that prompt recognition of friends, kindred, or foes which the social insects so well illustrate; there seems little doubt that the power of forming distinct images of external objects, after our fashion of seeing, is very slight in insects. The student should refer to the work of Sir John Lubbock on *The Senses of Animals* (Inter. Science Series, 1888). Similarly, to return to the functions of the nervous system, we can only notice that, in addition to the numerous and often subtle instincts which are ingrained in the constitution of many species, there is indubitable intelligence, as seen in the reasonable adaptation of means to novel ends; that, as in other animals, the intelligence is greatest in the social insects—especially the ants and bees, where it is associated with complex though very small brains. There is also plain evidence of emotion—e.g. in the love-making and parental affection of many insects. See ANT, BEE, BUTTERFLY, INSTINCT, and especially the works of Lubbock and Romanes.

Alimentary System.—The alimentary canal always consists of fore-, mid-, and hind-gut (see GUT), of which the first and the last portions are lined by a thin layer of chitin continuous with the external cuticle. But the length and structure vary not a little in different insects, to some extent in association with the differences of diet. The fore-gut includes mouth, pharynx, and gullet, of which the latter may be swollen into a crop, or bear an appended pouch (so called sucking stomach), or be continued into a gizzard with hard grinding plates. The mid-gut is glandular, digestive, and absorptive; it often bears saecular outgrowths or glandular cæca, and has, as its (endodermic) origin implies, no chitinous lining. In Coleoptera, for instance, its length, which is usually inconsiderable, varies inversely with the nutritive and digestible qualities of the food. The hind-gut is often coiled, terminally expanded in the rectum, and in that region sometimes associated with glands. Its general function is absorption, while from it there spring excretory tubes or Malpighian vessels (see *infra*). As to the food of insects, many are vegetarians, many carnivorous, a few mix both diets;

many feed on the juices of living organisms, others only on putrescence; many actively rifle flowers of their nectar and pollen, or hunt for other insects with great activity,

while not a few are external or internal parasites upon higher animals; the ant-lion digs a pit into which its unwary prey may fall, while dragon-flies attack their winged booty with open violence; among ants some milk the aphides, while others are so degenerate in prosperity that they are actually fed by their slaves. Nor should it be forgotten that some of the higher insects lay up stores of food, usually with parental instinct for the sake of their young, and that the eggs are often laid in the midst of the food suited to the larval

appetite, even in cases where the adults may perish before the young are hatched.

Respiratory System.—Insects when resting often show panting movements in the abdomen, which is swayed by muscles whose activity is the chief condition of the circulation of air throughout the body. For in all insects the whole body is penetrated by air tubes or *tracheæ*, which send fine branches into all the organs and tissues. These tubes are really ingrowths from the skin, and are lined by chitin, raised in what appear to be spiral thickenings which keep them elastically tense.

In most cases these tracheæ open to the exterior by paired apertures or *stigmata* on the breast and abdomen, often guarded by hairs and very variously disposed. There are never more, and usually fewer, than ten pairs of openings, though primitively there was probably a pair to each segment. In aquatic larvæ the tracheæ do not open (if they did the insect would drown), but are spread out on lateral or terminal expansions (tracheal gills), through the thin skin of which the oxygen dissolved in the water is absorbed (see DRAGON-FLY, EPHEMERA, GILL). The very efficient respiration of insects is one of the facts to be kept clearly in view in estimating the general activity of their life.

Here we may notice that many insects produce sounds which often express a variety of emotions. Thus, we have the whirr of rapidly moving wings, as in flies; the buzz of leaf-like appendages near the openings of the tracheæ in many Hymenoptera; the scraping of legs against wing-ribs, as in grass-

Fig. 6.—Portion of a branching Air tube of a Trachea, showing the internal chitinous ridges.

hoppers; the chirping of male crickets, produced by rubbing one wing against its neighbour; the shrill piping of the male Cicadas, which have a complex drum-like instrument; the voice of the death's-head moth, due to the emission of air from the mouth; and the tapping of the death-watch knocking on external objects. In some cases, where not simply automatic, the sounds serve the alluring purpose of love songs; they may also express fear, anger, and (according to Kirby) even sorrow, or they may give alarm and convey tidings.

Circulatory System. As the tissues are riddled with air-tubes, the need for definite blood-vessels is greatly lessened, and so the circulatory system is slightly developed in comparison with the literally thorough respiratory arrangements. The blood—which is colourless, yellow, greenish, or even reddish, with amoeboid cells—flows for the most part along lacunae without definite walls. There is, however, a central organ, the dorsal blood-vessel or heart.

Within the *body-cavity* of the insect there is often a characteristic mass of tissue known as the 'fat-body.' This is an important accumulation of reserve material, most abundant in the larval stages. In some cases the fat-body of the larva is rich in fat and poor in waste (urate) crystals, while that of the pupa is the reverse, showing that the material is used up in the reconstruction or metamorphosis. In a few insects, such as Fireflies (q.v.) and glow-worms, part of the fat-body seems to become the seat of phosphorescence, the light of which is in many cases a brilliant love-signal. See PHOSPHORESCENCE.

The *excretory system* consists of a set of fine tubes, or it may be threads, which grow out from the upper part of the hind-gut, and wind about often at great length in the body-cavity. The component cells contain abundant waste-products. In different insects the excretory or malpighian tubes vary greatly in number (2-150), and also in the manner of their connection with the gut. The usual type of invertebrate kidney—the nephridium—though persistent in *Peripatus* (q.v.), is not clearly discoverable in insects.

Reproductive System. The sexes are always separate in normal insects; and the Hermaphroditism (q.v.) which casually crops up is in most cases only superficial. In both sexes the reproductive organs are paired, and the products pass out by paired ducts. The latter—the oviducts of the female or the *vasa deferentia* of the male—always open near the end of the abdomen, and, except in the Ephemeroidea, by a single aperture; it is possible that they represent modified 'nephridia.' Accessory external and internal structures in the males may assist in copulation or in making the spermatozoa into packets; of similar structures in the females the most important are the occasional external ovipositors or egg-laying organs, and the internal seminal receptacle in which the spermatozoa received from a male are stored up, and serve to fertilise successive sets of eggs. In the queen bee this store has been known to last for two or three seasons, while Lubbock tells of an aged queen-ant which laid fertile eggs thirteen years after the last union with a male.

Male and female insects are usually somewhat different in external appearance. The males are, on an average, more active, smaller, and more brightly coloured than the females. Extremes are seen in male and female Coccid insects (q.v.); in the sexes of Glow-worm (q.v.); in a few Butterflies (q.v.), such as *Orgyia*, where the female is wingless; or in the curious bee-parasites *Strepsiptera*, where the female virtually remains a grub. As some insects have an elaborate courtship, in which the females choose their mates, and as some males

fight their rivals, there can be little doubt that Sexual Selection (q.v.) has accelerated the evolution at once of beauty and strength, while natural selection (see DARWINIAN THEORY, EVOLUTION) may have retarded the evolution of gay colouring in the females to whom conspicuousness is especially disadvantageous in parentage. Neither position is inconsistent with that which regards the characters of the two sexes as natural and necessary expressions of their respectively dominant constitutions. See Darwin, *Descent of Man*; Wallace, *Darwinism*; Geddes and Thomson, *Evolution of Sex*.

Peculiarities in Reproduction. (a) Virgin birth or parthenogenesis occurs normally, for a variable number of generations, in two butterflies and a beetle, some Coccid insects and Aphides, certain saw-flies and gall-wasps; it occurs casually in the silk-moth and about a dozen other Lepidoptera, partially or voluntarily in the drone-bearing of hive-bees, seasonally in Aphides (q.v.), and in larval life in some midges (e.g. *Chironomus*). (b) Where parthenogenesis occurs for a period and is thereafter followed by ordinary sexual reproduction, as in Aphides, we have to deal with one of the many forms of Alternation of Generations (q.v.). (c) A few insects are exceptional in being viviparous, bringing forth their young alive. This is again illustrated by Aphides, and also by a few flies, by the little bee-parasites *Strepsiptera*, and by some beetles. (d) Many insects are exceedingly prolific—e.g. aphid, silk-moth, and queen-bee. A climax is reached in the queen-termite which for a time goes on laying thousands of eggs (at the rate of about sixty per minute!).

Development of the Egg.—The ovum of insects, as it passes down the ovarian tubes, is enclosed in a firm chitinous envelope, with a minute aperture or micropyle (sometimes with more than one), through which a male element or spermatozoon penetrates before the ovum leaves the mother. The segmentation which follows fertilisation is for the most part peripheral (centrolecithal; see EMBRYOLOGY), while the centre of the egg is occupied by a relatively passive yolk with scattered nuclei. The result of segmentation is a sphere or ellipsoid of cells enclosing the core of yolk, and on the ventral surface of the sphere or ellipsoid the embryo

Fig. 7.—Ventral aspect of five stages in the development of the Water-beetle, *Hydrophilus* (after Heider):

The anterior end is uppermost, or head lobes; b, the last of the body-segments, which are seen becoming more marked throughout the series; round about the embryonic area the amniotic folds develop.

begins to be mapped out. This development we cannot here follow, but it is important to notice one unique fact, that the embryo is arched over by a double fold, constituting the internal amniotic and outer serous membranes, so called from their resemblance to the similar enswathing envelopes in the embryos of higher vertebrates. See Langs *Lehrbuch der Vergl. Anatomie* (vol. ii, Jena, 1889), where a summary of results and literature will be found.

Metamorphosis.—(1) In the lowest insects—the old-fashioned, wingless Thysanura and Collembola

—the young form which emerges from the egg-shell is in all respects a miniature adult. Without striking change, by growth and moultings, it becomes an adult. From this entire absence of metamorphosis we readily pass to the life-histories of cockroaches and locusts, of lice and most bugs, where the newly-hatched young are very like the parents. The reproductive organs are, of course, undeveloped, and there are no wings, but the latter are not attained even by the adult lice. All the above forms may be called *ametabolic*—i.e. without marked change or metamorphosis.

(2) In Cicadas there is a slight but most instructive difference between larvæ and adults. The full-grown insects live among herbage, the young live in the ground, and with this diversity of habit is associated at least this much difference in structure, that the anterior legs of the larvæ are adapted for burrowing. Furthermore, the larval life ends in a quiescent stage, or, in other words, the adult form is attained after a period of pupation. But the story becomes more complex when we pass to the Dragon-fly (q.v.), the Ephemera (q.v.), and their relatives, where the metamorphosis is slightly greater, inasmuch as the larvæ are aquatic, with closed respiratory apertures, and with tracheal gills, while the adults are winged and aerial, and breathe by open tracheæ. Such insects are said to have an incomplete metamorphosis, and are called *hemimetabolic*.

(3) Very different, however, is the life-history of all the other insects, such as butterflies and beetles, flies and bees. From the egg-shell there emerges a larva (maggot, grub, or caterpillar), which lives a life of its own, growing and resting and moulting, often very active in its movements and voracious in its diet. Having accumulated a rich store of reserve food in its fat-body, the larva becomes for a longer time more or less quiescent, becomes in fact a pupa, nymph, or chrysalis. In this stage, often within the shelter of a spun cocoon, great transformations occur: wings bud out, appendages of the adult pattern appear, reconstruction and centralisation of organs are effected; and finally, out of the pupal husk there emerges an imago or miniature fully-formed insect. These have a complete metamorphosis, and are called *holometabolic*.

The larvæ of these higher insects with complete metamorphosis differ greatly in different orders. Thus, the 'maggots' of flies (without distinct head, feelers, ocelli, &c.) are distinguished from the 'grubs' of bees (with distinct head), and both from the caterpillars of butterflies, &c., which have limbs as well as head. The limbless maggots and grubs are degenerate, the caterpillar is the more normal type. It is technically called an 'eruciform larva,' in contrast to that of most *Ametabola* and *Hemimetabola*—the 'campodeiform larva,' which is not even worm-like, but like one of the lowly *Thysanuran* insects (Campodea), with the regions of the body well defined, with biting mouth-parts, with locomotor thoracic limbs, &c.

But beyond distinguishing the above two great types of larva (campodeiform and eruciform), and also the maggot, grub, and caterpillar forms of the latter, little more is possible in this general survey, for the larvæ vary enormously, according to their own mode of life—parasitic or roving, aquatic or terrestrial, carnivorous or herbivorous—and according to the peculiarities of the adult forms. We must note, however, the changes in connection with the mouth-organs, especially as these form part of the basis of classification. The mouth-parts may be similar in all stages of life, and then are either adapted for biting (*Monognatha*—i.e. jaws persistent) or for sucking (*Meoarchyncha*—i.e. proboscis persistent); or else they are adapted in the larva for biting, in the adult for sucking, the change

commencing in the pupa, and rarely affecting the larval stage (*Metagnatha*—i.e. jaws changed). See Brauer's classification in Hatcher Jackson's edition of Rolleston's *Forms of Animal Life* (1888).

The Internal Metamorphosis.—One of the most interesting and difficult problems with regard to insects concerns the transition from the larval to the adult structure. In those forms which have no metamorphosis, or only an incomplete one, the organs of the larva develop continuously into those of the adult. It is far otherwise in the complete metamorphosis of the higher insects. There the internal changes are as marked as the external; in fact, there is a gradual reconstruction of organs during the later larval, and especially during the pupal stages. Most of the larval organs are absorbed by amoeboid cells, and their debris utilised in building up new structures. To a certain extent the development of new organs takes place by substitution; that is to say, parts of the larval organs which have not been specialised form the foundations of the adult structures. Of special importance is the appearance in the larva of 'imaginal discs' from which the wings, limbs, and epidermis of the imago or perfect insect arise. It must not, however, be supposed that the transition involves any abrupt change; the absorption, disappearance, and replacement of organs is gradual throughout. Yet almost the entire musculature, a great part of the tracheal system, the larger portion of the mid-gut, and many other parts of the larva disappear and give place to the corresponding organs of the adult which are adapted to a new mode of life. In pursuing this study the reader will best begin with Martin Duncan's *Transformations of Insects*, Lubbock's *Origin and Metamorphoses of Insects* ('Nature' series, Lond.), and then pass to the cited work of Lang and the literature there quoted.

General Life.—Under this title we can do little more than mention some general aspects of the life of insects. (a) While insects are predominantly active animals, we find in contrasting the orders, or better still, the families, abundant illustration of the antithesis (to be read throughout the animal series) between activity and passivity. Thus might the female cochineal insect represent in its torpid, sessile life one extreme, and the exceedingly busy humble-bee another. (b) In the majority of cases the adult insect is short-lived, and dies within the year; an adult Ephemerid may be literally the fly of a day, but from this there are many gradations leading up to the rare cases of a queen-bee five years old, or an aged queen-ant of thirteen. The total length of life, including the metamorphoses, varies not a little with the climate of different countries and the weather of different years, and the life is prolonged in those insects which hibernate, passing the winter in a lethargic state hardly deserving the name of life (see *HIBERNATION, LIFE*; Weismann's essay on 'The Duration of Life' in *Heredity*, 1889; and another essay by Ray Lankester on *Comparative Longevity*, 1870). (c) It is worthy of notice that reproduction in a great number of insects of both sexes is shortly followed by the nemesis of death, love being in such cases at once the climax and end of life. (d) In connection with the influence of climate and seasons the occurrence of different or 'dimorphic' summer and winter broods in some Lepidoptera should be noticed (see Weismann, *Studies on the Theory of Descent*, Meldola's trans. Lond. 1880-82; and Snodder's *Butterflies*, New York, 1881). (e) Nor can we do more than refer to separate articles for description of the fascinating social life of many ants, bees, wasps, and termites. (f) The prolific multiplication of insects is kept within bounds by the limitations of food-supply and weather, by the warfare between insects of different kinds, by the

appetite of higher animals, such as fish, frogs, ant-eaters, insectivores, and, above all, birds. As among other animals, we find among insects abundant illustration of peculiarities which have for their result at least the protection of their possessors. The leaf-insects, walking-sticks, moss-insects, humming-bird moths, scale-insects, &c. are striking examples of a protective mimicry in form and colouring which is illustrated in great variety and frequency throughout the class. Many larvae, as well as adults, show especially in colour a sympathetic relation to their environment, while others, such as Caddis-flies (q.v.), are masked by the external coverings with which they clothe themselves. Many insects are saved by their hard skins, by their disgusting odour or taste, by their deterrent discharges of repulsive fluids, by their assumption of 'terrifying attitudes,' by the simulation of death, or by active resistance with their manifold weapons. See MIMICRY; and Wallace's *Darwinism* (1889) and literature there cited.

Classification.—There is as yet a want of unanimity about the classification of insects. A basis is usually found in the degree of metamorphosis, the characters of the wings, the structure of the mouth-organs, and the nature of the genital and excretory ducts. On many points future embryological research will shed light. All that we shall do here is to give the general grouping adopted by Brauer. See cited text-books of Haldett Jackson and of Laug.

	16	<i>Hymenoptera</i> .—Ants, bees, wasps, gall-flies, saw-flies, &c. (Men. and Met.).
C.	15	<i>Coleoptera</i> .—Beetles (Men., rarely Met.).
METABOLA:	14	<i>Lepidoptera</i> .—Moths and butterflies (Met.).
MEMBRANATA	13	<i>Diptera</i> .—Flies (Met.).
and	12	<i>Siphonaptera</i> or <i>Phlebotomata</i> .—Fleas (Met.).
MEMBRANATA,	11	<i>Trichoptera</i> .—Caddis-flies (Men.).
Metazotha,	10	<i>Psocoptera</i> .—Scurvy-flies (Men.).
	9	<i>Neuroptera</i> .—Ant-lions, lace-winged flies (Men.).
B.	8	<i>Rhinocera</i> or <i>Hemiptera</i> .—Aphides, coccus insects, cicadas, bugs, water-scorpions, lice (the male Coccidae are metabolic).
AMEIABOLA:	7	<i>Thysanoptera</i> .—Thrips (A.).
MEMBRANATA.	6	<i>Coleoptera</i> .—Termites, bird-lice (A.)
	5	<i>Orthoptera</i> .—Cockroaches, locusts, crickets (A.).

AMEIABOLA	3	<i>Chironomata</i> .—Dragon-flies (H.).
and	2	<i>Ephemeroptera</i> .—May-flies (H.).
HEMIMETABOLA:	1	<i>Dermaptera</i> .—Earwigs (A.).
MEMBRANATA.	0	<i>Culicidaria</i> and <i>Blattaria</i> .—Primitive wing-less insects.

Distribution in Space.—Insects are represented almost everywhere. The majority are indeed terrestrial and aerial, and especially at home in warm and temperate countries, but in the Arctic regions and in hot springs, at great heights above the snow-line and in underground caves, and most surprisingly even in the sea there are insect inhabitants. The *Challenger* explorers found one or more species of the genus *Halobates* (among the Hemiptera) which seemed to be quite pelagic. The limits of distribution are in great part those of climate and of the requisite food, for insects have great possibilities of dispersal, not only in their often extensive flight and liability to be swept along by winds, but through the conveyance of the dormant eggs or even grubs from one shore to another within floating logs. Thus, tropical insects are brought on floating logwood from across the Atlantic, while locusts have been known to fly or to be blown in safety across more than 300 miles of sea. See GEOGRAPHICAL DISTRIBUTION, and works there cited.

History. Insects must have appeared in comparatively early times, for a cockroach-like wing has been found even in Silurian strata. Primitive dragon-flies and also lace-flies (Neuroptera) occur in the Devonian, cockroaches and walking-sticks

(Orthoptera) in the Carboniferous rocks. There seems much reason to believe that the Palaeozoic insects were mostly generalised, 'synthetic' types, prophetic of, rather than referable to, our modern orders. In the Trias Orthoptera abound; the first distinct beetles appear in the Lias, where other higher insects with complete metamorphosis also occur. See especially Scudder in Zittel's *Palaeontologie* (1885).

Pedigree.—As to their genealogy, suffice it to say that the wingless Collembola and Thysanura, at the base of the insect series, doubtless represent primitive forms; these lead us back to some of the less specialised myriopods, and these again to *Peripatus* (q.v.), the sole surviving genus of the ancestral Prototracheata. *Peripatus* links the air-breathing Arthropods to the ringed worms or Annelids, uniting, for instance, in its structure the trachea of an insect and the kidneys or nephridia of a worm. See Lubbock's *Origin, &c., of Insects*, and then the papers of Brauer, Emery, Packard, &c. cited by Haldett Jackson.

Economic Import.—Insects come into contact or collision with human interests in a great variety of ways. As far as they are concerned, the struggle between man and animals is by no means over. Strong in numbers, many of them are directly or indirectly injurious to man and his property to an extent which frequently affects the prosperity of a nation. Direct injuries to man's person are familiarly illustrated in the parasitism of fleas, lice, and other more or less intimate 'boarders,' but these are less important than the share the mosquito seems to have in the loathsome disease *Elephantiasis arabum*. The annoyance of midges is patent, but we feel the delicacy of the threads in life's web when we remember that the house-fly may disseminate the germs of bacterial disease. Personal injuries, however, are dwarfed when we think of those done to property, and especially to crops and herds, by voracious or by parasitic insects. Clothes-moth and furniture-borer, vine-insect and Colorado beetle, the bot-flies which attack sheep, cattle, and horses are familiar illustrations of formidable pests. It should also be noted how the hostile insects which infest forest trees and vegetation generally may occasion changes which have far-off effects on the fauna, scenery, and even climate of a country-side. In connection with injurious insects reference should be made to such articles as APHIS, BOT, CORN INSECTS, HESSIAN FLY, LOCUST, PHYLLOXERA, TSETSE, WEEVIL, &c.; to the well-known and inimitable *Introduction to Entomology*, by Kirby and Spence; to the admirable works of Miss Ormerod; and to the researches of Riley, Packard, and others, in the *Bulletins of the United States Entomological Commission*. From either of the last named sources a guide to the vast literature of this important department of entomology may be obtained.

As to the other side of the account, we cannot ignore our indebtedness to hive-bee and silk moth, to cochineal and lac insects, which furnish us with their unique and valuable products. Others again are indispensable and indefatigable scavengers; many wage effective war upon their injurious kindred; while a few, such as locusts and some

Fig. 8.—*Campoplex staphylinus* (after Lubbock), one of the primitive wingless insects.

larvæ, are even used as food. All these benefits, however, seem small in the light of the great fact that the majority of plants are dependent upon insects, as the unconscious bearers of the pollen essential to the normal cross-fertilisation of flowers.

Plants and Insects.—Referring to the article FLOWER for a statement of the importance of insects in the cross-fertilisation of flowers, we are safe in saying that neither the flowers nor their constant visitors can be understood apart. Many insects, however, injure plants without any compensating benefit, and in this connection must be noted the frequent occurrence of protective structures in plants, which help to dismiss hostile intruders. On the other hand, there are numerous cases in which plants and insects (especially ants) form a mutual partnership. Such 'myrmecophilous' plants are saved by their bodyguard of ants from unwelcome visitors, and the benefit is sometimes returned (to speak metaphorically) by the growth of special shelters or 'domatia,' tenanted by the partner insects. See GALLS, INSECTIVOROUS PLANTS, and the literature cited at FLOWER; also Kerner's *Flowers and their Unbidden Guests* (trans. Lond. 1878); and for references to the works of Delpino, Belt, Huth, &c., on 'myrmecophilous plants,' see Schimper's *Wechselbeziehung zwischen Pflanzen und Ameisen* (1888).

History of the Study of Insects (Entomology).—Insects had their due place in Aristotle's zoological system, and since thoughtful observation began have been studied with much constancy. Malpighi (1628-94), whose name is perpetuated in connection with the excretory tubules, was the first to give a thorough description of an insect's (the silk-moth's) anatomy. His contemporary Swammerdam got further in his investigation of insect metamorphoses. Ray (1628-78) and Linnæus (1707-78) helped to infuse system and order into entomology, while the works of Reaumur (1683-1757) are classical models of carefulness. Rosel von Rosenhof, Bonnet, De Geer, Schaffer, Fabricius, and Lyonnet were among the illustrious entomologists of the 18th century. Cuvier (1769-1832) began the study of insects in early youth with an enthusiasm which he never lost, and was wont to trace to the precision gained in his dissections of insects no small part of his success as an anatomist. Savigny's comparison of the mouth-appendages of insects and other Arthropods was an important step on a path often pursued since; and among the great entomologists of the first half of the 19th century, all more or less influenced by Cuvier's example, were Latreille, Kirby, Dufour, Burmeister, Audouin, Blanchard, Lacordaire, and J. O. Westwood. But beyond this the embarrassment of illustrious names makes compressed history more and more difficult; suffice it to notice the recent progress made in the study of the minute structure—e.g. of the sense organs of insects in experimental analysis of the sensory powers, in elucidating a natural classification, in deciphering the history both of fossil forms and of the individual organism.

Kirby speaks enthusiastically of the wealth contained in a well-stored cabinet of insects, of the problems suggested by the study of their anatomy and physiology, but rightly urges that 'we must behold insects when full of life and activity, engaged in their several employments, practising their various arts, pursuing their amours, and preparing habitations for their progeny; we must notice the hatching and kind of their eggs; their wonderful metamorphosis; their instincts, whether they be solitary or gregarious, and other miracles of their history.' Then we shall echo the words of Pliny, and of all entomologists: 'In these beings so minute, and as it were such nonentities, what

wisdom is displayed, what power, what unfathomable perfection!'

As reference has been made throughout the article to special works, it will be enough here to mention some of the general books—(a) zoological text-books, such as those of Claus, Gogenbaur, Huxley, Lang, and Hatcher Jackson's edition of Rolleston; (b) encyclopædia articles by Newport in Todd's *Cyclopædia of Anatomy and Physiology*, and McLachlan in *Encyclopædia Britannica*; (c) to the more popular natural histories—Cassell's (edited by Martin Duncan) and the Standard or Riverside (edited by J. S. Kingsley); (d) to general works—W. Kirby and W. Spence, *Introduction to Entomology* (4 vols. 1815-26; 1 vol. Lond. 1856); J. O. Westwood, *Classification of Insecta* (2 vols. 1839-40); Packard, *Guide to the Study of Insects* (New York, 1878); V. Graber, *Die Insekten* (2 vols. 1877); L. Camerano, *Anatomia degli Insetti* (1882); W. F. Kirby, *Elementary Text-book of Entomology* (1885); (e) for literature, Hagen's *Bibliotheca Entomologica*, the *Naples Zool. Jahresbericht*, and the *Zoological Record*.

Insectores (Lat., 'perchers'), or PERCHING BIRDS, an order of birds called by Cuvier Passerine or 'sparrow-like.' The order includes more than half the known birds, but can hardly be defined, since the members are marked off rather by a combination of characters than by any uniqueness. The title is usually now replaced by that of Passeres (q.v.).

Insolvency. See BANKRUPTCY.

Insomnia. See SLEEP.

Inspectors. See FACTORY ACTS, MINING, NUISANCES, POOR-LAWS, SCHOOL INSPECTORS, &c. In the military use of the term, there are two inspectors general of cavalry in the United Kingdom and two inspectors of auxiliary cavalry, also an inspector general of fortifications. The former inspect the several corps in their districts, and point out deficiencies, the corps being under the command, however, of its own officers, and not of the inspector-general. The latter is responsible for all fortifications and military works in the United Kingdom. District-inspectors of musketry have been replaced by district-assistant-adjutant-generals, and inspectors-general of hospitals by surgeons-general. Inspectors of infantry, artillery, volunteers, and militia have been abolished.

Inspiration, in Christian theology, is the influence of God on the writers of the Scriptures, which makes these Scriptures the Word of God. The word 'inspiration' is derived from the Vulgate translation (*omnis scriptura divinitus inspirata*) of 2 Tim. iii. 16, which in the revised English translation runs: 'Every Scripture inspired of God is profitable,' &c. The Greek word *theopneustos*, rendered 'inspired,' does not occur in classical Greek, and it might as fairly be rendered 'breathing the divine spirit,' as 'given by the divine spirit.' Belief in inspiration is not confined to Jews and Christians; all religions that are based on a divine revelation by means of sacred scriptures assume and affirm inspiration for that revelation. Orthodox Hindus regard the Vedas as of superhuman origin, and absolutely infallible. The Parsees hold that the Zend-Avesta was revealed to Zarathustra by the personification of the divine will which created the world. And the orthodox Moslem sees in the Koran an earthly copy of the original heavenly text revealed to Mohammed in his trances by the angel of revelation; though various Moslem sectaries, as the Motazilites, treat it with free rationalism.

No doctrine of inspiration is formulated either in the Old Testament or the New. But it may be said that the Jews generally have held a 'high' doctrine of inspiration; and the earliest Christian authors apply to Old and New Testaments the doctrine developed by Philo and the

Alexandrian Jews as to the Old Testament—that the writers were in an ecstatic condition or trance as interpreters of God's will, and as such were unconscious of what they spoke. Origen and later authors denied this *maotic* theory; though Irenæus and Augustine compare the writers of Scripture to the hands which wrote what Christ dictated. There was no definite church doctrine before the Reformation; the Reformers did not discuss fully the nature of inspiration, though the Reformation had emphasised the uniqueness and authority of the Scriptures. It was Calovius (q.v.) who laid down the theory that soon came to be regarded as the orthodox Protestant theory—that nothing exists in the Scriptures which was not divinely suggested and inspired. His followers made the writers dependent on the Spirit for their very words, their choice of expressions and grammatical forms being also divinely perfect. Buxtorf found the Hebrew vowel points inspired, and the Swiss *Fœderata Consensus Helveticæ* (see CONFESSIONS OF FAITH) extended inspiration to the punctuation.

The tendency of all schools of modern Protestant theology has been to pass wholly away from this mode of thought. Without at present regarding those who find in the Jewish and early Christian literature at most inspiring rather than inspired books, we find the extreme antithesis to the Calovian position in the view of those who, accepting divine revelation in the Old and New Testaments, find revelation and inspiration in all that makes the nature and will of God known to us—in the laws of nature as well as in the literature of devotion; and having regard to the fact that the Christian dispensation is a higher form of truth than the Jewish, hold that there is more of divine inspiration in such Christian books as the *Imitatio Christi* and the *Pilgrim's Progress* than in Esther or most part of the Old Testament. Between these extremes are to be found the dogmatic positions of all those who still cling to the Bible as the unique revelation of God in Christ. The differences of spirit are wide, and the divergences in statement innumerable. But they may be referred to a few main types.

Many hold the doctrine of *plenary*, as opposed to partial, inspiration—practically the view called by its enemies rather than by its supporters *verbal* inspiration. Thus Dr Charles Hodge teaches that 'all the books of Scripture are equally inspired. All alike are infallible in what they teach. Inspiration extends to all the contents of all these several books. It is not confined to moral and religious truths, but extends to the statement of facts whether scientific, historical, or geographical.' The object of revelation is to communicate knowledge, whereas that of inspiration is to secure infallibility in teaching. Dr A. A. Hodge holds that some received revelations who were not inspired to communicate them, as Abraham; that sometimes the writer was used by the Holy Spirit as an instrument in making a record of what conveyed to him no intelligible sense (1 Peter, i. 10-12); some, as Balaam, being unregenerate, were inspired though destitute of spiritual illumination. Of those who abide by this view some are more careful than others to protest against a *mechanical* doctrine, holding that they can allow fully for the individuality and special gifts of the various writers of Scripture; all errors are consistently denied, and discrepancies are explained away as trivial and merely apparent (see GOSPELS). The standard is the Scripture in the original tongues, the text being established by criticism. The canonicity of the existing books should on this theory be proved, but is sometimes practically assumed.

In opposition to this view it is sometimes affirmed that inspiration rendered the writers

infallible in teaching religious and moral truth, though they might err as to historical and scientific facts; or that inspiration was but a pre-eminent degree of that spiritual illumination which in a less degree is common to all Christians; or that, while Christ's personal teachings were infallible, the apostles and others were inspired in a less degree. Schleiermacher taught that the authority of the scriptural writers was proportionate to the closeness of their relation to Jesus Christ. Many, protesting against all 'mechanical theories and procrustean formulæ,' hold, with Archdeacon Farrar (in the *Clerical Symposium* cited below): 'The Bible is the book which contains the records of God's dealings with a chosen race, and through them with mankind. Above all, it is the book which contains the gospel of his Son and the lessons of salvation. It is not all of the same value. It is not all written on the same level. It contains some things which were permitted because of the hardness of men's hearts. . . . Much of it is written from the imperfect moral and spiritual standard of times of ignorance, at which God winked. You will find recorded in it without comment or disapproval some opinions and some actions even of good men which were not commendable. You will find attributed to God's command conduct which for us would be heinously criminal. Nevertheless, this book is a sacred book, for the sum total and general drift of its teaching is loftier and diviner than any you will find in the world. Both by its own loftiest utterances and by the Christian conscience which it has trained, and by the final standard of the gospel, it furnishes you with ample means whereby to judge what things are right and wrong. . . . The Bible is no homogeneous whole. It consists of sixty-six different books, the work of at least forty writers, written in different languages and dialects, and separate from each other by hundreds of years. It is not a book, but a library or a literature.' Or, as Horton puts it: 'We call our Bible inspired, because by reading it and studying it we find our way to God, we find his will for us, and find how we can conform ourselves to his will.' It is not more necessary that every word of the Bible should be infallible than that Peter and other apostolic men should never in their teaching have made mistakes, and this we know was not so.

In the Roman Catholic Church some theologians have asserted verbal inspiration; but this has never been the doctrine of the church. Distinguishing between inspiration and the assistance of the Holy Ghost, which would merely, as in the case of general councils, protect from error, the church recognises two factors in an inspired book—the natural powers of the writers on the one hand and the impulse and direction of the Holy Ghost on the other. But the church, which is the guardian of the canon and the interpreter of Scripture, has never defined where the one ceases and the other begins. Catholics have maintained the existence of trilling errors in Scripture; and Cardinal Newman sees no serious difficulty in admitting that there are 'obiter dicta' in Scripture which are not inspired.

See the article BIBLE in this work, as also APOLOGUES, EXEGESIS, ACCOMMODATION, DIVINATION, AUGUSTINE, GOSPEL; the article by Cremer in Herzog, the supplementary article in Schaff's *Religious Encyclopedia*, and that in Addis and Arnold's *Catholic Dictionary*; the relevant parts of the works of Hodge, Oosterzee, Deane, Pfeiderer; Hagenbach's *History of Doctrines*, and works on inspiration by Wordsworth (1861), Gausson (Eng. trans. 1851), Lee (1851), Elliott (1877), Brown (1880), Given (1881), R. F. Horton (1888), Cardinal Newman in the *Nineteenth Century* of February 1884; *Inspiration: a Clerical Symposium*, by the representatives of various

views 1884); A. B. Bruce, *The Kingdom of God* (1889); C. Gore in *Our World* (1890); Sanday's Bampton Lecture on *Inspiration* (1894); and the innumerable works on the subject referred to in the books named.

Instinct, the mental aspect of those actions which take rank between unconscious reflex activities and intelligent conduct. When we observe the lowest forms of life gliding slowly towards their food, or the roots of plants overcoming obstacles in their search for soil and moisture, we recognise activities certainly advantageous, yet so comparatively simple that they almost admit of direct physical and chemical explanation. More complex activity is at once apparent when we watch the fly-trap or sundew catching insects, or notice the protective responses which most animals make to provoking or startling stimuli. These imply an inherited and well-established relation of parts (usually nerve and muscle), such that a frequently recurrent form of stimulus provokes an immediate, definite, and more or less appropriate response. Such actions usually depend on what is figuratively called a neuro-muscular 'mechanism'—i.e. on the power that subordinate nerve-centres have of responding to stimuli without bringing the chief centres (or brain) into exercise. They may therefore occur even in cut-off parts of animals, or after the organism is virtually dead. Higher than these, however, are the marvellous activities, most familiar perhaps in insects and birds, for which more or less of a brain is essential, which are so engrained in the organism that they require no practice, which often adapt means to ends, but show little power of adjustment to novel conditions, which are finally the birthright, not of elect individuals, but of all the members of a species. But as we review the animal series in ascending order we become more and more impressed with yet higher actions, for which a head-centre or brain seems essential, which often require to be learned and are perfected by practice, which adapt means to ends in novel circumstances, and vary greatly among individuals.

So far we have kept apart such words as mind, intelligence, instinct, consciousness; but that is no longer possible or desirable, for the last three grades of activity described above are not only observable facts, but are also parts of our personal experience, and must be considered in that light. Like animals, we of course exhibit immediate neuro-muscular responses to external stimuli: witness the sudden withdrawal of our finger from a burning object unwittingly touched. Such responses, for which brains are not necessary, occur 'without our knowing,' and are called *reflex*. Next on the scale come numerous actions, from the sucking of infancy onwards, which require no practice, deliberation, or effort, but yet have a distinct mental aspect, being usually associated with consciousness, and stimulated rather by perceptions than by sensations. Such actions, learned so long ago that the power of doing them is now entailed by heredity, are more predominant in animals than in ourselves, and are called *instinctive*. Higher than these, and pre-eminent in man, are the actions which deliberately adapt means to ends, with conscious intention and controlling *intelligence*. These lead on to the most characteristically human actions, in which we often seem to hold ourselves as unities apart from what is outside us, and in which we are influenced by general ideas and definite ideals, being in fact self-conscious men. So far there is practical unanimity, but difficulties inevitably arise when we begin to project upon animals our own experience of reflex, instinctive, and intelligent actions. We are forced to argue by analogy, and therefore with uncertainty. It is allowed, however, by almost all that the old-fashioned attempt to call all the higher activities

of animals instinctive, in sharp contrast to the intelligent conduct of man, merely expresses an ignorant prejudice. No competent observer denies that ant and bee, dog and elephant, heaver and monkey, frequently exhibit actions higher than instinctive, in some cases quite parallel to that human conduct which we call intelligent. This, however, does not of course assert that any animals have attained to the human level of self-conscious intelligence, with its ideas and ideals. In thinking about the grades of action, which are usually regarded as stages in evolution, it is well to distinguish the objective or observable characteristics from the subjective or analogical interpretation; and it is also important to recognise that the grades distinguished are not hard and fast, but simply mark areas on an inclined plane which slopes from the amoeba up to man.

Definitions.—We are not concerned here with the general questions suggested by such descriptions of instinct as refer it to 'immediate impressions from the First Mover or from the divine energy acting in the creature,' nor is it necessary to discuss those which make the term include all the adaptive actions of animals in sharp contrast to the intelligence of man. Some others, however, are more to the point. Thus, Hartmann defines instinct as 'action taken in pursuance of an end, without conscious perception of what the end is.' Spencer calls instinct 'a kind of organised memory.' Samuel Butler says 'instinct is inherited memory.' J. J. Murphy describes it as 'the sum of inherited habits.' According to Eimer, 'instinct is inherited capability, and especially inherited habit; or more exactly, instinct is the inherited power of acting habitually and without deliberation in a purposeful, intelligent fashion, under the influence of internal stimuli, plus or minus others from without.' According to Romanes, 'instinct is reflex action into which there is imported the element of consciousness. The term is therefore a generic one, comprising all those faculties of mind which are concerned in conscious and adaptive action, antecedent to individual experience, without necessary knowledge of the relation between means employed and ends attained, but similarly performed under similar and frequently recurring circumstances by all the individuals of the same species.'

Examples.—Instinctive actions are usually perfect from the first and independent of individual experience. Thus, the butterfly makes the remarkable transition from caterpillar to adult habits without hesitation or failure; the bee rifles flowers on its first flight; and the chick in the first few hours of its open-air life makes successful darts at flies. In other cases, however, practice appears to help, as in the nest-building activities of birds. Nor are instincts always sufficiently perfect, for ants store beads instead of grains, and mistake corn-wheat seeds for their own cocoons; flower-visiting insects also patronise bright-coloured wall-paper; and the lemmings in their instinct for going right ahead will swim straight out to sea. Marvellous are the instincts exhibited by social animals such as ants and beavers, by insects which provide elaborately for young which they never survive to behold, and in the nesting and migration of our common birds. Less pleasant, in fact almost devilish in ingenuity, is the instinct of the Spheg wasps, which provide fresh meat for their future larvae by storing spiders, insects, and caterpillars which they have stung in their chief nerve-centres, with the result that the victims are not killed outright, but only paralysed.

Origin of Instincts.—An approximation to the truth will probably be attained by combining the chief theories. (1) Instincts may be the inherited results of compound reflex actions, and are there-

fore in origin unintelligent (Spencer). (2) Natural selection may fix on purposeless habits which chance to be profitable, and convert them into instincts without intelligence being ever concerned in the process (Darwin, Romanes). Weismann points out that not a few instincts are exhibited only once in a lifetime, so that they at least can hardly be the inherited results of practice. He holds that 'all instinct is entirely due to the operation of natural selection, and has its foundation not upon inherited experiences, but upon variations of the germ.' (3) Instincts may arise from habits, which were originally intelligent, becoming by repetition automatic (Darwin, Lewes, Romanes, &c.). Eimer derives instincts from inherited intelligent habits, which are shortened and simplified in evolution, though frequently retaining a trace of deliberation. (4)

Diagram illustrating origin of Instinct from reflex action on the one hand, from lapsed intelligence on the other (cf. Romanes).

While instincts may arise by natural selection alone, or by lapsing intelligence alone, 'these principles when working in co-operation have greater influence in evolving instincts than either of them can have when working singly' (Romanes). (5) Imitation, as Wallace insists, and the power of rapid learning, which Eimer emphasises, have probably been of importance in the evolution of some instincts. It seems certain that instincts may arise either from unintelligent or from intelligent habits, that their evolution may be abetted by natural selection, and that the power of instinctive action is conserved by the organic memory of inheritance.

See ANT, BEAVER, BEE, BIRD, CUCKOO, ELEPHANT, &c. for illustrations; also BRAIN, EVOLUTION, HEREDITY. For full illustrations, see especially G. J. Romanes, *Animal Intelligence* (Inter. Sc. Series, 1882); Couch's *Illustrations of Instinct*; Lauder Lindsay's *Mind in Animals*; Büchner's *Aus dem Geistesleben der Thiere* (trans.), &c. For theory of instinct, see especially Romanes, *Mental Evolution in Animals*, with a posthumous essay on Instinct by Darwin (1883); compare Darwin's *Origin of Species*; Wallace's *Natural Selection*; Spencer's *Principles of Psychology* and *Principles of Biology*; G. H. Lewes, *Problems of Life and Mind*; S. Butler, *Life and Habit*; J. J. Murphy, *Habit and Intelligence*; Carpenter, Maudsley, Bastian, Wundt, and others on Mental Physiology; E. Von Hartmann, *Das Unbewusste vom Standpunkte der Physiologie* (2d ed. 1877); Schneider, *Der thierische Wille* (1880); Preyer, *Die Seele des Kindes* (1882); Eimer, *Die Entstehung der Arten* (1888); Weismann, *Papers on Heredity* (1889).

Institute. THE, in English law, is the mode of citation or reference to Chief Justice Coke's great work on English law, the name for the first part of which is *Coke upon Littleton* (see COKE). *Institutes* is the name given to the elements of Roman or civil law. See LAW, JUSTINIAN.

Institute of France. See ACADEMY.

Instrumentation is the art of using, in composition, the various instruments and combinations of the Orchestra (q.v.).

Insurance is a contract under which one party, called the Insurer, or Assurer, agrees, in consideration of a sum of money called the Premium, to pay a larger sum of money to another party, called the Insured, or Assured, on the happening of a designated contingency. Insurance has sometimes been said to be akin to gambling, but it is really the converse. The gambler seeks excitement and

gain by the artificial manufacture of hazardous speculations. The prudent man resorts to insurance in order to secure peace of mind and immunity from the loss which might arise from contingencies beyond his control. The gambler creates or exaggerates risks; the insurance office equalises them.

The origin of insurance is lost in antiquity. At a very early period merchants insured their vessels and goods against the perils of the seas, and probably *marine insurance* was the first description to come into existence. From insuring ships and merchandise, the step was not a long one to insure for the voyage the life of the captain, on whom so much depended; and we therefore soon find traces of such contracts, the insurance frequently providing for the sum assured to be paid, not only in the event of the death of the captain, but also in the event of his capture by pirates, or by the king's enemies. Moreover, the merchant in those early days frequently accompanied the vessel in which his goods were shipped. Possibly he had obtained the goods on credit, on condition of paying double their cost should he return safely, and the creditor would thereupon insure the life of the merchant for that particular voyage. *Life assurance* proving in this connection very convenient, it gradually was resorted to in other business transactions, and ultimately came to be sought as a means of family provision.

The first evidence of *fire insurance* is to be found in connection with the Anglo-Saxon guilds, although probably it also was a development of marine insurance. The reader will find full information on the historical aspect of the subject in the various articles in Walford's *Insurance Encyclopaedia*, and in an essay on the 'History of Life Assurance in the United Kingdom,' by the same author, in the *Journal of the Institute of Actuaries* (vols. xxv. and xxvi.).

Life Insurance.—The earliest life-assurance policy of which particulars have been preserved was made on 15th June 1583 at the 'Office of Insurance, within the Royal Exchange,' in London. Full details of this policy have been preserved, because it gave rise to the first authentic disputed claim. The policy was for £383, 6s. 8d., to be paid to Richard Martin in the event of William Gylbons dying within twelve months, and the policy was underwritten by thirteen different persons who guaranteed sums of from £25 to £50 each. The premium was at the rate of 48 per cent. William Gylbons died on 28th May 1584, and the underwriters refused to pay because he had survived twelve months of twenty-eight days each. The Commissioners appointed to determine such cases held that the twelve months mentioned in the policy meant one full year, and they ordered the underwriters to pay. These appealed to the Court of Admiralty, which then had jurisdiction in such cases, and where in 1587 two judges upheld the decision of the Commissioners, so that eventually the underwriters had to pay.

The existing company known since 1698 as the Hand-in-Hand was started in 1696 under the name of the Amicable, and is therefore the oldest insurance company in existence, but it did not begin life business until 1836. The earliest known life-assurance company was established in 1699, and called the 'Society of Assurance for Widows and Orphans.' This was what now would be called an *assessment* company. It did not guarantee a definite sum assured, in consideration of a fixed periodical premium, but by its constitution it was to consist when full of 2000 members who were to contribute 5s. each towards every death that occurred among the members; this contribution being designed to raise £500 on the death of each member, contingent on all members paying up.

The next life-assurance institution started was the famous Amicable (a different company from the Amicable already mentioned). It was founded in 1705, and chartered by Queen Anne on 25th July 1706. Walford, in his *History of Life Assurance*, states that the plan of working was this: The number of members was to be 2000. Amongst the representatives of those who died in the first year one-sixth of the total contributions was to be divided; in the second year, if the full number of members was enrolled, £4000; in the third year, £6000; in the fourth, £8000; in the fifth and subsequent years, £10,000, with a proportionate reduction if the full number of members was not enrolled. The full contribution from the complete roll of members would be £12,000 per annum, and the surplus was to be accumulated. The Amicable lasted as an independent institution until 1806, when it was transferred to the Norwich Union Life Insurance Society, and its policies were finally merged in those of the Norwich Union on 30th June 1886. Various other life offices of the assessment order were started about the same time, but all except the Amicable disappeared on the bursting of the South Sea Bubble in 1720. In 1721 the London Assurance Corporation and the Royal Exchange Assurance Corporation, both of which had been chartered in 1720, received additional powers, under which they were authorised to transact life business. These twins both remain strong corporations at the present day, and are therefore the oldest surviving life offices in the world. The first life policy of the London Assurance Corporation was issued on 7th June 1721. The only other life office which we shall mention here is the Equitable, established in 1762, and prosperous still. Its history for now more than a century and a quarter has been the history of life assurance in England. Its affairs have been conducted by men eminent in the assurance profession, and to its cautiously directed enterprise in early days we are in great part indebted for the scientific soundness of the foundation on which the business of life assurance stands. Since the passing of the Life Assurance Companies Act in 1870 it has been possible to trace minutely the history of every life company. Owing to amalgamations they are diminishing in number. At the time the Act of 1870 was passed there were about £30 in active operation, a number reduced in 1890 to only 88. Under the Act of 1870 a deposit of £20,000 must be made with the Court of Chancery before a company may commence life business, and this discourages the formation of new offices.

The elementary principles of life assurance are very simple. At first the rates of premium were fixed in a purely arbitrary manner, the result of guess work, and no difference appears to have been made in respect of persons of different ages. But as experience was gathered it came to be seen that history repeats itself with great precision; that out of a given number of persons alive it can be approximately foretold from the results of the past how many will die within a given time; and it was further seen that the rate of mortality has a tendency to increase with the age of the lives observed—that is to say, for instance, that out of a thousand persons alive aged thirty fewer will die in a year than out of a thousand persons aged sixty. The first result of this advance in scientific knowledge was that a limit of age was fixed beyond which applicants were not admitted into the assurance offices, the Amicable refusing all aged forty-five and over; a little later on the Equitable was started upon the still more scientific principle of charging rates varying according to age. Early investigators tried to embody the

results of experience in tabular form, and so produced forerunners of what are now known as mortality tables. These show, out of a given number born, how many complete each year of age, and by means of a properly constructed mortality table the rates of premium which should be charged for the assurance of lives can readily be calculated. John de Witt, Grand-pensionary of Holland, was apparently the first to apply scientific principles to the calculations connected with annuities, which are analogous to those connected with assurances, his report on this matter being distributed to the members of the States-general on 30th July 1671. The first mortality table was based upon observations in the city of Breslau, and was prepared by E. Halley, Astronomer royal of England, and published in the *Philosophical Transactions* for January and March 1693. The first tables of premiums used by the Equitable Society were prepared from the mortality of the year 1741 by James Dodson, author of the *Mathematical Repository*, who was associated with Thomas Simpson, the well-known mathematician, in founding the society. Later on the Equitable adopted tables derived from the London bills of mortality, and later on still, that known as the Northampton table, constructed by Dr Price from the statistics of the parish of All Saints, Northampton, during forty-six years from 1735 to 1780. The earliest mortality tables were prepared from a record of the deaths alone; but it was subsequently discovered that this gave erroneous results, and had a tendency very much to exaggerate the estimate of mortality. Joshua Milne, actuary to the Sun Life Assurance Society, seems to have been the first to construct mortality tables correctly by comparing the numbers dying in each year of age in a population with the numbers alive at each age. On this principle he constructed the famous Carlisle table, based upon the population of the parishes of St Mary and St Cuthbert, Carlisle, in 1780 and 1787, and the number of deaths that took place in each interval of ages in the same two parishes during nine years, beginning with 1779 and ending with 1787. The Carlisle table formed for many years the basis on which were calculated the premiums and the reserves of a great many of the leading insurance companies, and so accurate was it that even at the present day its use has not been entirely discontinued. The records of the Equitable Society furnished materials for the construction of mortality tables from the experience of assured lives, and Griffith Davies, F.R.S., actuary to the Guardian Assurance Company, compiled the Equitable assurance table (1825) from data he derived from the annual addresses of the actuary of that office. Later on a committee of actuaries collected the experience of seventeen insurance companies, and the results were published in 1843. Again, the Institute of Actuaries collected the experience of twenty companies and gave it to the world in the volume of *Mortality Experience* in 1869; and these last tables are at the present day considered the best, and with British insurance companies are rapidly superseding every other. Many individual companies have also taken out their mortality experience, and tables have been prepared from the experience of foreign companies by American and continental actuaries.

In the calculations of a life office the probabilities of life are combined with the interest of money. To take the simplest possible example: According to the Institute of Actuaries' mortality table, out of 1000 children aged ten 956 will attain the age of twenty-one. Now, assuming that exactly 4 per cent. compound interest can be realised, the sum required to be invested at once in order to provide

£100 at the end of eleven years is £61, 19s. 2d. If it be arranged that each of the 1000 children aged ten shall receive an endowment of £100 on coming of age, it is clear that 956 such endowments must be arranged for, and the amount now required to provide them is £62,100, 3s. 4d. In respect of each of the 1000 children, therefore, a sum of £62, 2s. must be paid down if he is to receive £100 on reaching his majority. This sum is called the present value of, or the single premium for, the endowment. An annuity consists of a series of endowments, the first payable at the end of one year, the second at the end of two years, and so on; and its present value, or the sum required to purchase it, is found by calculating the value of each of these endowments and adding the whole together. Similarly, if a sum of money is to be paid on the death of an individual, a calculation is made for the premium to cover the risk of death in the first year; so also for the second year, for the third year, &c., to the utmost possible duration of human life; and the results are added together in order to find the single premium for an assurance on his life. For the annual premium an equation is made between the value of an annuity on the life and an assurance on the same life; and thus the annuity—in this case called the annual premium—equivalent to the single premium is ascertained. In order that such calculations may be made easily and simply various monetary tables are in the first place prepared, and the calculations, which would otherwise be so laborious as to be almost prohibitive, are thereby rendered very brief and easy. On principles similar to those adopted in such simple cases as are above indicated, actuaries are able to solve many complicated problems. For instance, it is easy to ascertain what should be the premium for an assurance payable in the event of one person of a given age dying before another person of a different age; or many lives may be introduced with various orders of survivorship. The simpler questions of this nature may be solved directly from the mortality table and the subsidiary tables which are usually prepared from it; but when very complicated questions arise other processes must be resorted to. The late Sir J. W. Lubbock, Bart., in the *Cambridge Philosophical Transactions* for the year 1829, was the first to give a formula of approximation. Mr W. S. B. Woolhouse, in the *Journal of the Institute of Actuaries* (vols. xi. and xv.), produced a formula essentially the same as that of Lubbock, but different from it in that he used the differential calculus instead of the calculus of finite differences. Mr G. F. Hardy, in the *Journal of the Institute of Actuaries* (vol. xxiv.), greatly extended and improved Mr Woolhouse's formula, and threw it into various shapes to suit different circumstances, so that for practical purposes these formulas can now be applied to solve the most complicated questions in a very easy manner. Later on Mr Woolhouse again took the matter up, and, in the *Journal of the Institute of Actuaries* (vol. xxvii.), investigated the general principles upon which these formulas of approximation are based, and deduced several of still greater power than those which had previously been put forward. Little more therefore remains to be done in this direction.

It has already been remarked that the rate of mortality increases with the age. The usual custom of insurance companies is, however, to charge a uniform premium throughout life, and it naturally follows that this premium must be in excess of that required for the mere assurance in the earlier years when the mortality is comparatively light, so that that excess may be accumulated at interest, and become available in the later years of the policy when the rate of mortality is

heavier, and when the uniform premium charged is no longer sufficient for the risk. In this respect life assurance differs from fire insurance. With fire insurance a reserve is required only for the unexpired portion of the time for which the premium has been paid, and to provide against fluctuations and contingencies. In life assurance also, a reserve is required for these objects, but, in addition, a reserve is necessary, as above pointed out, on account of the increasing rate of mortality. Hence it follows that life companies transacting business by uniform premiums must accumulate large funds, which are not profit, but are absolutely necessary in order to meet prospective liabilities. This is clearly shown when a company, as sometimes happens, closes its door to new business, and determines simply to continue its existence in order to run off current contracts. For a time the funds will increase, but presently it will happen that the claims will absorb the whole of the premium and interest income. A little later on the claims will be in excess of such income, and the investments will have to be drawn upon, until when the last policy falls in the funds will be completely exhausted. In the early days of the Equitable Society, when it was uncertain what would really be required to cover the risk, much larger premiums than ultimately proved to be necessary were charged; and, as there were no shareholders, the large surpluses which accumulated were distributed among the policy-holders. This system became so popular that when other companies were started at a later date, although the rates of mortality were much more accurately understood, an additional premium, over and above that required for the risk and for expenses, was deliberately charged, so as to provide a fund out of which bonuses might be paid to the policy-holders. It is now the universal custom of life offices to have a participating class of policy-holders, among whom the periodical surpluses are distributed. There are many ways in which these so-called profits are divided. With some companies the bonuses are large in the early days of a policy, and gradually diminish as time goes on. Others again give comparatively small bonuses at the outset, these increasing with the lapse of time; and others again give practically uniform bonuses throughout the duration of the policy. Some companies make it a feature to return the surplus in cash, or as a reduction of the premium. Others treat the share of surplus belonging to the individual policy-holder as a single premium to provide an assurance on his life, in this connection called a reversionary bonus; so that instead of paying away at once the money to the policy-holders, the sums assured under the policies are increased. Other companies combine these various methods, and give policy-holders their choice. The systems being essentially so different, it is difficult to compare one company with another, and the intending policy-holder should judge for himself which system would best suit his own circumstances, and act accordingly.

The Institute of Actuaries, founded in 1848, was incorporated by royal charter in 1884. Its journal, regularly published now for over forty years, contains a vast number of most important and useful original contributions on the theory and practice of life assurance. All the leading actuaries have contributed, and every discovery of importance in actuarial science has first been published in its pages. By its meetings, at which papers are read and discussed, the institute has also done much to promote the investigation and to disseminate the knowledge of life contingencies. In early days it initiated the system of examinations, and gave certificates of competency to students who satisfactorily passed them, so that the directors of

insurance companies could know who were the men qualified for posts that might become vacant. Later on lectureships were added to train the students, and under the auspices of the institute a text-book in two parts has been published, dealing respectively with interest and annuities certain, and with life contingencies; the former by W. Sutton, M.A., and the latter by the writer of this article. Another great achievement of the Institute of Actuaries was the collection of the materials for the mortality experience of twenty companies, and their compilation in the form of mortality tables and monetary tables. The Faculty of Actuaries of Edinburgh and the Actuarial Society of Edinburgh have also done good public service.

The Life Assurance Companies Acts, 1870-72, were passed owing to the disastrous failure of two great companies, the Albert and the European; and under them companies must register their accounts in specified form, and at periodical intervals give very full details relating to their actuarial valuations. The view taken by the British legislature has been that it is well to allow the companies to be managed by their own responsible officials, and that the government should not actively interfere, but that for the protection of the public full information should be available. The acts also have proved a great benefit by providing for the reconstruction instead of liquidation of insurance companies. A third great advantage of the acts has been that reckless amalgamations have been rendered impossible, while amalgamations that are for the good of all the parties interested have not been interfered with. Now such full details of everything that is done in connection with an amalgamation must be published, that anything like extravagance or unjustifiable expenditure is impossible.

Fire Insurance, Marine Insurance.—The contract of fire insurance is a contract purely of indemnity—i.e. the assured may not make a profit out of a fire, but is merely indemnified against loss sustained. Therefore it is not the cost of the goods at the time of purchase that is taken account of in settlement of a loss, but their value at the time of the fire. For instance, if a merchant have stored cotton for which he gave £1000, and if a fire occur when his stock would realise only £800 if placed upon the market, then £800 is the limit of the amount he can recover, although he may have been holding the cotton for an advance in prices. Again, if a householder have a claim upon a company, he can only recover in respect of the value of his furniture and effects, after allowing for the depreciation due to wear and tear—i.e. by the contract of insurance he is entitled only to be placed in the position which he occupied immediately before the fire, and not in one better. In this important respect fire insurance differs from life assurance, because in the case of a life policy, the amount of the interest of the assured is fixed at the time the policy is issued, and he may on the death of the life assured recover that full amount, although at the time of the death his interest may possibly have altogether ceased. The contract of fire insurance differs also in important respects from the marine insurance contract. In the latter, if goods are assured for less than their value, the policy-holder carries the risk himself for the amount uninsured. For instance, if a merchant have goods on a vessel to the value of £1000, and if he insure for £500, and if damage to the goods occur to the amount of £500, he can recover only £250, he being his own insurer for the difference between the value of the goods and the amount of the policy (for fuller information on Marine Insurance, see AVERAGE). In the case of the fire insurance contract, however, the whole £500 could

in such event be recovered from the company, unless in the exceptional case of an average clause having been inserted in the policy. By the average clause the insured is made his own insurer for whatever amount is not covered by fire policies, and it is sometimes inserted in policies covering large trade risks, and also in those covering goods stored in scattered warehouses. By the usual wording of fire policies, the company has the right to refuse a renewal premium, and here again there is a marked difference from a life policy, which is renewable at the option of the assured, but not of the insurer. A fire policy is not assignable without the consent of the office, which it is usual to give by the way of indorsement. Thus, if a merchant whose goods are covered by insurance sell the goods, the protection of the fire policy is not thereby transferred, but the purchaser must make his own arrangements. Thus, in the common occurrence of the purchase of a house, although the house may have been covered by a policy in the name of the vendor, the purchaser cannot recover under it without an indorsement having been placed upon it transferring the insurance from the vendor to himself. The contract of fire insurance is personal between the insured and the office, and the insured can therefore recover only the amount of his own personal loss. Thus, for instance, unless so stated in the contract, the goods of a servant are not covered by the fire policy in the name of the master; and goods in the hands of an agent are not covered by a policy in the agent's name. As the wording of fire policies is very strictly construed by the courts of law, and as the offices for their own protection are often compelled to take their stand on the literal contract, though they seek to meet liberally every *bona-fide* claim, the policy-holder should be careful to see that his policy is in accordance with his wishes.

Prior to 1869 a special tax was imposed on fire insurance companies, and the returns they were called upon to make furnished an accurate record of the amount of fire insurance business transacted in the country. In 1869, however, the tax was repealed, and a stamp of one penny only on each policy was substituted. The result is that, except in the metropolis, where for the metropolitan fire-brigade, under act of parliament, a rate is paid by the companies in proportion to the amounts assured, it is impossible to say what is the total business of the country. Many of the companies voluntarily publish their accounts, and show their premium income, and those with a life department must do so; but in the case of purely fire offices this is not compulsory.

Fire offices may be broadly distinguished as tariff and non-tariff. The tariff are those which belong to the Fire Offices' Committee, an association formed for mutual protection, and, by the regulation of rates, to obviate destructive competition. The non-tariff offices are those which profess to estimate each risk on its merits, without fixing a minimum, but most frequently those offices which try this plan find it unsatisfactory, and subsequently join the tariff. Great Britain is eminently the country of successful fire offices, and several of the British companies are larger than any established in any other part of the world. Many of the British offices transact an enormous foreign business.

Industrial Insurance is the name given where life policies are of small amount, and secured by weekly, or at most monthly, premiums. The premiums vary from 1s. to 3s., or 6d. a week, and it is usual, instead of the premium being adjusted to the age, to adjust the sum assured; so that, while at all ages the premium is the same, the amount of the policy decreases with the age of the life at entry. An

enormous industrial business is transacted in Great Britain, partly by insurance companies and partly by collecting Friendly Societies (q.v.). One industrial company alone—the Prudential, established in 1848—received in industrial premiums in 1889 the huge sum of £3,336,742.

Accident Insurance generally provides for a sum payable in the event of death by accident, or for compensation, either by way of a lump sum or of a weekly allowance, in the event of injury or disablement from accident. Even in early times there are traces of accident business, but the oldest and largest existing accident company is the Railway Passengers', established in 1848. At first, as its name implies, it confined its operations exclusively to railway accidents, and accumulated a premium income of £12,000 a year, but before long it enlarged its powers so as to transact accident business of every description, and in 1896 its premium income was £2,740,000. Besides transacting accident business proper, many of the companies combine with it employers' liability assurance—i.e. they guarantee to refund to employers any damages they may have to pay through accidents to workmen in their service; but without the greatest care this department of the business is unremunerative. Some of the accident companies also issue policies providing weekly compensation in the event of incapacity from illness; but generally it has been found that, on account of the difficulty in defining illness, and on account of the great liability to fraud, sickness insurance has been unprofitable.

Fidelity Guarantee Insurance.—The first attempt at fidelity guarantee insurance appears to have been made in 1720, but it was many years before the business took root. The first fidelity office—'The Guarantee Society'—was established in 1842. The object of fidelity guarantee insurance is to secure employers against fraud on the part of their clerks and servants.

In the *United States of America* an enormous life business is transacted by the native companies, and one of them, the Mutual Insurance Company of New York, is the largest office in the world, while several of the others far surpass in magnitude any British company, except perhaps the Prudential. The premium income of the Mutual of New York in 1889 was £4,745,572, and the new business transacted in that year amounted to £30,310,912—more than ten times that of any British office. The aggregate premium income of the forty leading American offices in 1889 was £28,199,804, while the total premium income of all the ordinary life-assurance companies of the United Kingdom was only £13,928,001. It must, however, be remembered in comparing these figures that three of the American companies—viz. the Mutual of New York, the Equitable of New York, and the New York Life—are almost cosmopolitan in their nature, and transact a gigantic business throughout the civilised world, whereas the great majority of British companies transact but a small foreign business.

American insurance law differs in very many respects from that of Great Britain. The principles have been adopted of strict state supervision, and of a standard of solvency. In each of the states there is an officer charged with the duty of examining into the affairs of insurance companies, of making valuations, and of reporting the results of his investigations; and if the assets are not sufficient to meet the liabilities as legally estimated, the company is compelled to close its doors. As each state of the Union legislates on insurance matters quite independently of all the others, considerable confusion has been produced. In different states different standards of solvency are set up, and it might quite well happen that in one state a company might be adjudged bankrupt, while in

another the commissioner might on the same day give his certificate that it was in a position to meet all its engagements. Practically, however, these anomalies do not cause much inconvenience, and the various states are gradually assimilating their regulations. One principal feature of the American system of transacting business is the Tontine (q.v.) system, which has grown to gigantic proportions. In England, in almost all cases, the surpluses are distributed among the policy-holders by way of immediate bonuses, but in America the great majority of policies are issued on the condition that profits will accrue only if the life survive and if the policy be kept in force for the stipulated period. The effect of this condition is that when profits do vest, they are of course larger than if the policy-holders had received immediate bonuses. In former times not only were the profits placed in a Tontine, but the policies themselves were subject to a similar arrangement; so that unless the renewal premiums were punctually paid, the policies would lapse and the assured would derive no benefit from them.

In the *British colonies* life assurance has also developed in a marvellous manner; and, considering the relative populations, Great Britain is left far behind. The Australian colonies in particular are pre-eminent for the success of their insurance offices, the Australian Mutual Provident Society of Sydney being the largest, and giving perhaps the largest bonuses of any company in the world; this result being due in part to excellent management, but principally to the very high rate of interest which invested funds yield at the Antipodes. On 31st December 1896 the Australian Mutual Provident Society had on its books 128,996 policies assuring £40,623,903, at annual premiums of £1,332,715, and the invested funds amounted to £13,728,540.

While in the Australian colonies insurance laws differ in various respects from those of the United Kingdom, yet they are still further removed from the regulations of the United States of America. There is no standard of solvency, and no government supervision in the ordinary sense of the word; but companies have to make returns somewhat on the British system, so that the public may have full information. In France, Germany, and Austria there are also large insurance companies.

National Insurance.—From an early period the British government has been accustomed to grant annuities on lives, the transactions being carried out by the National Debt Commissioners. The annuity business having been very large and very successful, it was naturally thought that an insurance business providing for sums payable at death might with equal propriety be undertaken, and consequently, through the medium of the post-office, a life-assurance office was started on the 17th April 1865, but in the magnitude of results it has not answered expectations. In the year 1889 the amount received in premiums was only £15,108, 7s. 2d., and the amount paid in claims £7473, 3s. 10d., and the total premium receipts from the opening of the office up to 31st December 1889 were only £226,069, 4s. 8d., being very much less than the revenue of many of the private offices for a single year. Probably the reason for this comparative failure of the British life-assurance department is that no efforts are made to develop the business, and no commission is paid to agents.

New Zealand has also initiated a system of national insurance, but there the practice of private companies has been followed, and with eminent success. Canvassers have been appointed, and commission paid to agents; with the result, that while the department was instituted only in 1874, yet in the year 1896 the premium income was

£790,956, and at the close of that year the accumulated insurance fund amounted to no less than £2,591,342.

Germany is the only country which has attempted compulsory national insurance, and that on a large scale. The first bill was passed in 1883, and provided for the compulsory insurance of workmen against sickness. In 1884 a further act was passed providing compulsory insurance against accidents; and in 1889 a third bill became law under which the working-classes will on disablement from illness or accident, or on attaining old age, receive a pension. It cannot be said that the insurance laws of Germany are based upon strict actuarial science, but they are a bold attempt to solve a very difficult problem. In the United Kingdom there is perhaps not the same need for a compulsory insurance law of this drastic character, because the poor-law practically has the same end in view.

Intaglio (Ital., 'cutting in'), a term in art, the opposite of relief, means the representation of a subject by hollowing it out in a gem or other substance, so that an impression taken from the engraving presents the appearance of a bas-relief. See GEM.

Integral Calculus. See CALCULUS.

Intellect. See PSYCHOLOGY.

Intemperance. See ALCOHOLISM, DELIRIUM TREMENS, INEBRIATES, INTOXICATION.

Intendant, the name given in France before the Revolution to the overseer of a province. Under the complete system of centralisation established by Richelieu these intendants became the mere organs of the royal minister. The National Assembly, in 1789, established in each department an elective administration. Napoleon virtually restored the intendants, but exchanged the hated name for that of *Préfets* (q.v.). Intendant is the name of the person in charge of an estate, and there are *intendants militaires*, *intendants de la marine*, &c.

Inter'calary (Lat. *intercalaris*, 'for insertion'), an epithet applied to those months or days which were occasionally inserted in the calendar to make it correspond with the solar year. See CALENDAR.

Intercommuning. LETTERS OF, was an ancient writ issued by the Scotch Privy-council warning persons not to harbour rebels.

Interdict, an ecclesiastical censure or penalty in the Roman Catholic Church, consisting in the withdrawal of the administration of certain sacraments, of the celebration of public worship, and of the solemn burial-service. Interdicts are of three kinds—*local*, which affect a particular place, and thus comprehend all, without distinction, who reside therein; *personal*, which only affect a person or persons, and which reach this person or persons, and these alone, no matter where found; and *mixed*, which affect both a place and its inhabitants, so that the latter would be bound by the interdict even outside of its purely local limits. The principle on which this ecclesiastical penalty is founded may be traced in the early discipline of public penance, by which penitents were for a time debarred from the sacraments, and from the privilege of presence at the celebration of the eucharist; but it was only in the mediæval period that, owing to circumstances elsewhere explained (see EXCOMMUNICATION), it came into use as an ordinary church censure in the then frequent conflicts of the ecclesiastical and civil power. It was designed to awaken the national conscience to the nature of the crime, by including all alike in the penalty with which it was visited. The most remarkable interdicts are those laid upon Scotland in 1180 by Alexander III.; on Poland by Gregory VII., on occasion of the murder of

Stanislans at the altar; by Innocent III. on France, under Philippe Auguste, in 1200; and on England under John in 1208. The description of England under the last-named interdict, as detailed by some of the contemporary chroniclers, presents a strangely striking picture of the condition of the public mind, which it is difficult with our modern ideas fully to realise or to understand. It would be a great mistake, however, to suppose that during the continuance of an interdict the people were *entirely* destitute of spiritual assistance. The interdict mainly regarded the *solemnities* of public worship; it was permitted to administer baptism, confirmation, and the eucharist in all cases of urgency; to confess and absolve all who were not personally the guilty participators in the crime which the interdict was meant to punish; to celebrate marriage, but without the solemnities; and to confer orders in cases of necessity. And under the popes Gregory IX., Innocent III. and IV., and Boniface III. still further mitigations of its rigour were introduced, one of which was the removal of the interdict and restoration of public worship on certain great festivals, especially Christmas, Easter, Pentecost, Assumption, and All Souls. The Council of Basel enacted very stringent rules as to the use of this penalty, and in later times the general interdict has been entirely disused, although occasionally, in very special circumstances, and to mark the horror of the church for some enormous crime, instances are still recorded in which a particular place or church has been visited with the penalty of a local interdict.

Interdict, in Scots law, is an order issued by the Court of Session to stop or prohibit a person from doing an illegal or wrongful act. The party applying for it must have both title and interest to object to the act complained of—i.e. he must be more than a mere stranger. The principles on which it is granted in Scotland are substantially the same as those in which the parallel Writ of Injunction (q.v.) is granted by the English court.—For *Interdiction*, see FACILITY.

Interest is the consideration paid for the use of money. The interest of £100 for one year is called the rate *per cent.*; the money lent, the principal; and the sum of any principal and its interest, the amount. The current or market rate of interest varies from a variety of causes, the chief of which are the relation existing between the accumulation of money and the demands of borrowers, the prevailing rate of profits on trade, and the security and duration of the loan. In Great Britain the price of the public funds indicates the interest obtainable for a permanent loan with no risk of loss, while the 'bank rate'—i.e. the minimum rate at which the Bank of England will discount bills—represents the interest for temporary loans with less undoubted security. In the former case, as with fixed annuities, the nominal rate of interest never varies; but the real return to the investor depends on the price he has to pay for the capital. Thus, if the price of 2½ per cent. consols be 91½, the actual return will be 3 per cent.

Interest is computed on either of two principles. SIMPLE INTEREST is charged on the principal alone for any length of time. The computation of simple interest is easy, resolving itself into a mere question of proportion; thus, having given the interest on £100 for 1 year, to find the interest on any other sum for any period. Various ingenious devices are made use of to save labour in these calculations, especially by bankers, and are given in most hand-books. COMPOUND INTEREST is the charge made where—the interest not being paid when due—it is added to the principal, forming the amount upon

which the subsequent year's interest is computed. The rules for most readily making computations by compound interest can only be effectively expressed algebraically, and, using i to represent the interest of £1 for one year, and n the number of years, we annex a few of the elementary formulas for £1, from which the result for any sum is obtained by simple multiplication.

(1) *Amount of £1 for a given time at compound interest.*—At the end of the first year the principal (£1) with its interest (i) will become $1 + i$. At the end of the second year the amount will be $(1 + i) + i(1 + i)$, or more simply $(1 + i)^2$, and, generally, *the amount of £1 in n years is $(1 + i)^n$.* Example: To find the amount of £6 in 20 years at 5 per cent. interest. Here i is .05 and n is 20, whence the required amount is $6 \times 1.05^{20} =$ (by logarithms) $6 \times 2.65 =$ £15.18.

(2) *Present value of £1 due n years hence.*—Since £1 becomes $1 + i$ in one year, by proportion $\frac{1}{1 + i}$, otherwise written $(1 + i)^{-1}$ or v , will become £1 in the same time, and hence the present value of £1 due n years hence is $(1 + i)^{-n}$ (or v^n).

At 5 per cent. simple interest a sum of money doubles itself in 20 years, while at compound interest with the same rate it takes less than 15 years. In 100 years £1 at 5 per cent. simple interest becomes £6; at 5 per cent. compound interest it becomes £131, 10s., or thereby.

(3) **ANNUITIES CERTAIN.**—*Amount of an Annuity of £1 in n years.*—At the end of the n years the last year's annuity will be due, and therefore worth £1; the second-last will be worth one year's interest in addition, or $1 + i$; the third (reckoning backwards), $(1 + i)^2$; and so on to the first year's annuity, which will amount to $(1 + i)^{n-1}$. The amount required is therefore the sum of the geometrical series $1 + (1 + i) + (1 + i)^2 + \dots + (1 + i)^{n-1}$; or, $\frac{(1 + i)^n - 1}{i}$.

(4) *Present Value of an Annuity.*—This is easily found from (3), as the result there found must evidently be the present value, improved at compound interest—i.e. multiplied by $(1 + i)^{-n}$. Hence the present value is $\frac{1 - (1 + i)^{-n}}{i}$; or, $\frac{1 - v^n}{i}$.

Tables for the four classes of values above described, based on various rates of interest, are given in most works on annuities and other handbooks; and various useful results, besides those immediately intended, can readily be deduced from them.—The calculation of *Life Annuities* is complicated by the element of the probability of life, and is treated under ANNUITY.

INTEREST, IN LAW.—The charging of interest was formerly looked upon with great disfavour, and was either forbidden or restricted by the Usury Laws (q.v.), which were not finally repealed till 1839. In English law there is no obligation imposed on the debtor to pay any interest whatever, though the sum has been long due and often demanded. The creditor can always sue for his debt, which is his proper remedy, but he derives no benefit from giving time to his debtor. Therefore, if interest is to be paid, this must be, as a general rule, by virtue of express agreement. A tacit agreement, however, would be presumed and given effect to where it could be proved to be a custom between the parties, or the usage of a particular trade to allow interest. Thus, by the usage of merchants, it has always been usual, when an action has been brought to recover the amount of a bill of exchange or promissory note, for the jury to add interest from the time it was due. In the case of money due upon an award by an arbitrator interest is due from the day when the award was

made. Where money is due on a bond also interest is added from the day it ought to have been paid; and if a surety has to pay money for his principal he can recover it back with interest. In all other cases, if there was no express agreement about interest, none could be claimed. By 3 and 4 Will. IV. chap. 42, sec. 28, a jury may now add interest at the ordinary rate on all debts or sums certain, which are made payable under some written instrument at a certain time; and even if not due under a written instrument, then if a written demand has been made, expressly giving notice that interest will be charged from and after the date of the demand if not paid then, interest will also be due. But even in these last cases it is discretionary in the jury to give the interest, and therefore it is not claimable as a matter of course. As regards compound interest, it is *a fortiori* not claimable in any case, except where it has been expressly stipulated for, or where there is in some particular trade a definite custom to pay interest, and such custom must always be proved. The courts generally name 4 per cent. when interest is decreed for, but sometimes 5 per cent.; and where funds have been misapplied the Court of Chancery charges compound interest at 5 per cent. Pawnbrokers are allowed to charge interest not exceeding a fixed sum. See PAWNBROKING.

In Scotland the law has always been much more liberal in allowing interest to be claimed on outstanding debts, for there the converse principle was acted on, that on nearly all debts whatever interest was claimable either by statute or by common law. Thus, interest is due on bills of exchange, on the amount contained in a horning or charge to pay, on sums paid by cautioners, on the price of lands sold, on money advanced at request, on the price of goods sold if the usual time of credit has expired, and generally on all debts when payment is due and has been demanded. In certain cases principal and interest to a fixed date are accumulated into a capital sum on which interest runs; and the House of Lords, on appeal, may give decree for compound interest. The courts charge penal interest at the rate of 20 per cent. against factors and trustees who illegally retain trust funds in their own hands.

In the United States the legal rates of interest vary in the different states and territories, from 5 per cent. in Louisiana to 12 in Wyoming, but in the majority 6 per cent. is the legal rate. In most of the states there are penalties for usury, ranging from forfeiture of the excess of interest to forfeiture of principal and interest. But a higher rate, and in many cases any rate, is allowed by contract.

Interference, in Physical Science, is a term which refers to a very general class of phenomena depending on the co-existence at one place of two different sets of waves, undulations, or vibrations. Its essential character is well illustrated by the mingling of two sets of ripples produced in any way (such as by the dropping in of stones) on the otherwise smooth surface of a sheet of water. Where crest meets crest, and trough meets trough, there the resultant disturbance is increased; but where crest meets trough, and trough meets crest, the disturbance will be diminished, and even annihilated should the mingling ripples be equal to begin with. In such a case we can observe the interference of individual waves. Now, wherever we have wave-motion, in the wide dynamic sense of the term, there we may have interference-phenomena showing themselves. But if, as in the case of the propagation of sound, light, and electrical waves, the undulations are too small, or of a character too peculiar to be *individually* observed or felt by any

of our senses, we cannot hope to have evidence of interference-phenomena unless there is a steady succession of two trains of waves reproducing the same phenomenon at the same place for an indefinite time. Thus, two different rays of light will not in general produce evident interference-phenomena. It is only when they have been brought from the same original source, and made to pursue slightly different paths, that the optical effects of interference are possible. As a simple illustration, take Grimaldi's experiment as modified by Dr Thomas Young (1804), to whom we owe the discovery of the principle of interference and its application to optical phenomena. A ray of light, which for simplicity we shall regard as homogeneous—that is, of one wave-length and colour—is introduced into a darkened chamber through two minute apertures very close together. The two similar divergent rays of light so produced will interfere, and the result, as shown on a screen placed a short distance in front of the apertures, will be a series of bright bands separated by dark spaces. The central bright band, every point of which is equidistant from the apertures, is produced by the superposition of two rays, crest falling with crest, and trough with trough. The next bright band on either side is the locus of all points whose distances from the two apertures differ by a wave-length of light, so that still crest falls with crest, and trough with trough. But at the points that lie in the centre of the intermediate dark space the two rays meet so that crest falls with trough, and trough with crest, and thus produce darkness instead of brightness. The general law is that darkness is produced when the portions of the two interfering rays that coexist at one point were in the original single ray distant from each other by an odd number of half wave-lengths; and that brightness is produced when this distance is an even multiple of a half wave-length. Theoretically an indefinite number of interference bands should be visible; but practically this is not so. The chief reason for the gradual fading of the further bands is the difficulty of obtaining sufficiently pure homogeneous light. If the light is ordinary sunlight it will be found impossible to get really dark spaces, since in this case the component rays, being of different wave-lengths, cannot interfere in the same way. Thus, if the red rays interfere so as to annihilate each other, the blue rays will not do so, but may on the contrary interfere to intensify each other. Hence arise the coloured bands always to be seen when interference-phenomena are produced with non-homogeneous light. Amongst other optical illustrations of the principle of interference we may mention the coronæ round the sun and moon when they are seen through a fleecy cloud, the spurious bows that fringe the primary rainbow, the colours of soap films and thin plates generally, the colours of mother-of-pearl and diffraction gratings (see SPECTRUM), Newton's rings, and, as a simple experiment, the appearance of a candle or lamp flame when looked at through a fine cambric handkerchief. The phenomenon of spring and neap tides (see TIDES) is another case of interference; so also are shadows, both light-shadows and sound-shadows. Moreover, Dr Hertz of Carlsruhe has taught us how to obtain and measure the interference of electro-magnetic waves. See MAGNETISM.

Interglacial Beds. See PLEISTOCENE.

Interim, in the history of the Reformation, the name given to certain edicts of the German emperor for the regulation of religious and ecclesiastical matters 'in the meantime' (Lat. *interim*), till they could be decided by a general council. The chief are the *Ratisbon Interim* (at the diet held at Ratisbon in 1541); the *Augsburg Interim* (diet of

1548); and the *Leipzig Interim* (another diet of 1548). See CHARLES V.

Interlaken ('between the lakes'), a village of Switzerland, in the beautiful valley of the Aar, between Lakes Thun and Brienz. Along the Walnut Avenue or Highway between the lakes there is an almost uninterrupted line of hotels and *pensions*. The village is visited annually by 20,000 to 30,000 tourists, who make it their starting-point for reaching many of the most wonderful sights that the country affords, especially the Bernese Oberland, where are the Staubbach, Lauterbrunnen, the Grindelwald glaciers, &c. Pop. 2121. The nucleus of the village is a former Augustinian monastery (founded 1130).

Interlineations in a deed are additions or corrections written either on the margin or between the lines. In England interlineations in a deed are not fatal, provided only it is proved that they were made before executing the deed. It is usual to put the parties' initials opposite the place where the interlineations occur, in proof of this, or at least by way of memorandum. In affidavits and other documents the initials should also be put at the places interlined. In Scotland interlineations ought to be signed by the parties, and the fact mentioned in the testing clause, otherwise it will be presumed that the interlineations were made after the execution, and will vitiate the deed.

Interlocutor, in Scotch law, means a finding or judgment of a judge or court in a cause.

Interlude, in Music, is a short melodious phrase played by the organist (generally extempore) between the verses of a psalm or hymn tune. It is now in disuse in England. In French cathedrals a long interlude is played between the verses of the *Magnificat*. In the German Protestant Church an interlude (*Zwischenspiel*) is often played between each line of the verse. Examples of its artistic use may be found in Mendelssohn's *Elijah* ('Cast thy burthen') and *St Paul* ('Sleepers, wake').

Intermittent Fever. See AGUE.

International, THE. The International Working-men's Association was founded at London in 1864. It was, however, not the first attempt to establish an international combination of workmen. As early as 1839 a number of exiles, chiefly German, had taken part in an unsuccessful rising at Paris, and removing to London had formed a league in the interests of labour. Containing workmen from most of the countries of northern Europe to whom German served as a common tongue, the league naturally assumed an international character. It entered into relation with Karl Marx in 1847, and under his influence was reconstituted under the name of the Communist League. In its name Marx and his friend Fr. Engels drew up the manifesto of the Communist party, an expression of the most violent revolutionary and international socialism. The manifesto was published on the eve of the revolution of 1848, and the members of the league represented the most extreme section of the fighting democracy in Germany during that time of trouble. The failure of the revolution was soon followed by the dissolution of the league.

The association of 1864, usually called the International, began in the visit of some French workmen to the International Exhibition in London, 1862. This visit was encouraged or supported by the Emperor Napoleon. In London the Frenchmen fraternised with their English brethren; wishes for common action in the cause of labour

were interchanged, a course which was furthered by the desire of the emperor, through the workmen, to influence public opinion in favour of Poland. Finally, in September 1864, at a great meeting in London, it was decided to establish an international association of working-men.

Mazzini was first commissioned to draft a constitution for the association, without satisfactory result; and the task fell upon Marx, who, in the inaugural address and in the statutes, embodied the aims of the new movement with masterly force and clearness. Notwithstanding the enormous progress of industry in recent years, Marx contended that the lot of the workmen had not improved; that the economic subjection of the worker under the monopolist of the instruments of labour, that is, of the sources of life, was the cause of servitude, in all its forms, of social misery, intellectual degradation, and political dependence; and that the economic emancipation of the working-class, therefore, was the great end to which every political movement should be subordinated as means. Fearing that the new hopes now awakened might be rendered vain through the want of union, he maintained that the emancipation of the working-class was neither a local nor a national, but a social task, which concerns all countries where modern society exists, and whose solution depends on the practical and theoretical co-operation of the most advanced countries. The association declared that all societies and individuals adhering to it recognise truth, justice, and morality as the rules of their conduct to each other and to all men without distinction of colour, creed, or nationality; no duties without rights, no rights without duties. While intended to act as a centre of combination and systematic co-operation between the workmen of various countries, the International left intact the organisation of existing societies which might join it. There was to be an annual congress, which should name the general council, and the general council would hold in its hands the control of the association.

The statutes drawn up by Marx were adopted by the first congress held at Geneva, 1866; and the socialistic principles which from the first were implied in its constitution received explicit development at that and subsequent congresses, Lausanne (1867), Brussels (1868), Basel (1869). The meeting at Brussels was in every way the most decisive; it declared that mines, land, and means of communication should become the common property of the state, and by it be handed over to associations of working-men to be utilised under conditions favourable to the common good; and that only through co-operative societies and the organisation of mutual credit could the workmen own and control the machines. The congress further condemned all appropriation by capital of rent, profit, or interest; labour should enjoy its full right and entire reward. Against the war then imminent between France and Germany, and against war generally, the congress raised a solemn protest, and recommended a universal strike in the event of its breaking out. At the congress of Basel a proposal for the abolition of the right of inheritance was not carried.

Apart from the meeting of congresses, it is not easy exactly to define the development of the International. Though speedily suppressed by the French government, it had some influence in directing and supporting strikes in that country, while it assisted English trades unions by preventing the importation of cheap labour from the Continent. It had adherents in every country of western and central Europe; but its influence always depended more on the vast and undefined possibilities of the cause it represented than on its

actual strength. Its finances were weak, its organisation loose; the adhesion of many of its members was of a very platonic character. Undoubtedly the most real and effective gain to the International was in Germany, where the workers' unions constituting the Eisenach branch of the Social Democracy declared their adhesion to it.

In 1870 the International proposed to hold its annual congress at Paris, the ancient seat of the revolutionary movement, but the Franco-German war intervened to prevent it. The revolt of the Commune with its disastrous consequences rendered a congress impossible also in 1871. The International had little or nothing to do with originating the Commune; only a few of its members were involved in the rising, and on their individual responsibility. After the suppression of the revolt, Marx in the name of the general council wrote a trenchant manifesto fully endorsing the action of the Commune. He saw in it a rising of the proletariat against a clique of *bourgeois* adventurers who had seized on the central power of France. It was a revolt of the proletariat, the class of which socialism claims to be the special champion; and it was an assertion, against the centralising government of the middle classes, of the political form requisite for the development of socialism, the commune or self-governing local group of workers.

From the first the control of the International had depended mostly on a group of German exiles, of whom Marx was the undoubted chief. The followers of Blanqui and Proudhon exercised some influence, but it could not be compared with that of Marx. In 1869 Bakunin, the apostle of anarchism, with a body of followers entered the International. Naturally they objected to the authority and centralising methods of Marx, and at the Hague congress of 1872 a rupture ensued. The anarchists were expelled from the association, the seat of which was also transferred by the Marx party to New York. In 1873 both parties held congresses at Geneva, which did nothing notable. The Marx International really ceased to exist from that time. The Anarchist International, which was most powerful in the Romance countries, such as Spain and Italy, continued to act for some years subsequently; and particularly it was responsible for the risings in the cities of southern Spain in 1873-74, where the insurgents seized on part of the ironclad fleet, and were suppressed not without difficulty.

No formal organisation styling itself International now exists, but the socialist parties of the different countries, especially those adhering to the Marx school, fully recognise the international character of the movement in which they are engaged. Foremost in every respect among those parties is the German Social Democracy, with its strongly pronounced indifference and even hostility to many of the accepted national interests of the country. Since the downfall of Marx's association international socialism has found expression in congresses, as that of Ghent in 1877. In 1889 the centenary of the Great Revolution, two large international congresses assembled at Paris, one representing the more uncompromising Marx school, the other consisting of delegates who are not indisposed to co-operate with other democratic parties. The proposal made in 1889 by the Swiss government for an international conference on the protection and regulation of labour did not excite much attention; but it was felt that the whole question had entered on a new stage when in the spring of 1890 the German emperor assembled a similar conference at Berlin. It is needless to say, however, that this International of the European governments

concerned itself with only a small portion of the great task undertaken by the association so called. An international demonstration of workmen in favour of the compulsory limitation of the working day to eight hours took place in most populous European and American centres on May 1, 1890 (in London the principal gathering was on Sunday, 4th May).

See Laveleye's *Socialism of To-day*; John Rae, *Contemporary Socialism*; R. Meyer's *Emancipationskampf des vierden Standes* (vol. i. contains the documents bearing on the International); E. Villetard, *Histoire de l'Internationale*.

International Law. Under this designation are included two distinct branches of jurisprudence, known respectively as Public International Law and Private International Law. Public international law regulates the relations of states to states; private international law is concerned exclusively with the legal relations of private individuals, determining by the law of what nation such relations shall be governed in each particular case. Further, it has to be noted that a variety of relations may occur wherein a state and the citizen of another state are the subjects. Here the law is public on one side and private on the other, as is the law administered in prize-courts. In practice, however, such cases are treated under public international law.

Public International Law is the name given to the aggregate of rules which govern the conduct of separate states in their relations to each other. For many years the majority of writers on international law in England and America were content to look for the origin of these rules in no higher source than the more or less general consent of nations, and to base them on no more stable foundation than the shifting sands of expediency. Jurisprudence thus became a merely arbitrary system of rules founded on tacit contracts or express conventions, and its precepts were, logically enough, considered susceptible of any degree of modification, limitation, or adaptation that temporary convenience might seem to demand. These unfortunate doctrines were introduced into English jurisprudence chiefly through the teaching of Bentham, by whom utility was put in the place of natural law. His principles were wrought out and more specifically applied by John Austin, whose works long continued to dominate English jurisprudence. This principle of utility, viewed simply as a good practical test in legislation, or as a ready guide in applying the rules of natural law to the complex facts of state life, may often prove of high value; and, according to Sir H. S. Maine, it was in this aspect, as a 'working rule of legislation,' that Bentham proposed his formula of the 'greatest happiness of the greatest number.' As a matter of fact, however, the majority of the advocates of utility claim that in itself it furnishes the rule of life, and so supplies the place of natural law, the existence of which they deny.

These doctrines have never found much currency on the Continent, and their prevalence in England and America has unfortunately had the effect of cutting off the jurisprudence of these countries from the general stream of scientific jurisprudence which in the nations of continental Europe has continued to run in the old channel. In recent years, however, both in England and America there is observable a growing tendency to abandon this arbitrary notion of positive law. This movement has been largely aided by the scientific spirit, and by the close investigation of nature. Similar researches on the ethical and social sides of human nature have been equally fruitful, with the result that the idea of the universal prevalence of law in all departments of life has been vindicated, and

the faith of mankind in nature as a reasoned organism has been confirmed.

As a science, accordingly, positive international law has for its object the discovery of those laws which determine the relations of nations to each other. In all branches of municipal law, the law of the relations subsisting between citizens is defined and enunciated by a legislative authority, is applied by a judicial authority, and is enforced by an adequate executive. The positive law thus defined is accepted on all hands, and consequently a scientific investigation of natural law is only necessary on those rare occasions when alterations are being made in the enacted law. In the case of international law, in the absence of all legislative, judicial, and executive authority, there really is in the strict sense no positive law at all. There are few even of its central doctrines which are not the subject of warm dispute; the objects to be aimed at are no less undetermined; its history is in many respects fragmentary and inconsistent. The truth is, as Professor Sheldon Amos has remarked, that international law now exhibits a positive system of law in the process of making.

The natural laws governing the relations of nations must have been coeval with the existence of nations. It nevertheless remains true that international law, as a positive system, is substantially the creation of civilised Europe during the last three centuries, and its rules are now practically operative only among civilised states. In spite of the fact that the division of the Greek world into a number of separate communities would seem to us to favour the rise of such a system of law, it would appear that, beyond the recognition of certain common Hellenic customs, no effort was made to systematically enunciate any rules of international intercourse. The glory of Greece was already waning when the Stoics, tracing out in a more ethical and practical direction the principles of Socrates, arrived at the idea of the *persona* and, giving a definite form to the conception of the brotherhood of mankind, enunciated the doctrine of the *jus naturale*. In this doctrine lay the germs of a cosmopolitan system of international law. In Rome the *jus civile* of the early republic—regulating the formal intercourse between Rome and other states—looks like the beginning of what under other conditions might have developed into a system of international law. Unfortunately during the whole period of the empire, while the municipal law of Rome under the influence of the Stoical conceptions was achieving its high destiny, the jurists were by their theory of a universal empire entirely shut out from applying their principles to the relations of states to states. So too, long after the Roman empire had given place to separate kingdoms, while the labours of the civilians contributed largely to the consolidation of the new societies, the imperialistic traditions still lingering among them prevented any effort being made to evolve the doctrines of a *jus inter gentes*. Meanwhile, the peoples of Europe, closely bound in the fetters of an omnipotent feudalism, were painfully struggling through a period of transition, out of which were to emerge the great European monarchies. During this long period the need of some definite system of international law was in some measure practically supplied by two powerful influences—the authority of the church and the institution of chivalry. The magnificent organisation of the church, besides checking violence and controlling in some degree the turbulence of princes, enabled the pope, taking advantage of the lingering notions of universal sovereignty, to act as arbitrator in a great variety of controversies ranging in importance from the disputes of private individuals to the adjustment of difficulties of serious

international concern. The institution of chivalry also, by introducing declarations of war by heralds and a more humane treatment of the vanquished, and generally by inculcating the virtues of fidelity and magnanimity, tended to assuage the horrors of war. Meantime the revival of commerce and the growth of the new commercial cities gave rise to several primitive maritime codes (e.g. the laws of Oleron, the laws of Wisby), whose publication did much to regulate the relations of states in mercantile matters. At length, as the nations of Europe passed into manhood, there came the dawn of a new era and a general rekindling of intellectual life. At the same time the Reformation gave a death-blow to the old notion of a common superior whose decisions were binding upon states, and shattered the influence so long beneficially exercised by the Roman curia as a great court of international appeal. Perplexed by the terrible events of the long struggle between Spain and the revolted Netherlands, and appalled by the unbridled license of the Thirty Years' War, Europe cried aloud for deliverance from what threatened to become international anarchy. The time was ripe for the development of a system of international jurisprudence. The renewed study of Greek philosophy had revived the doctrines of the *jus naturale*, and in the application of these old principles in the new direction of a *jus inter gentes* was found the solution of the problem of international order. The first clear reference to the law of nations, as a separate branch of positive law, and as such distinguishable from the law of nature, is usually found in the work of Francis de Suarez of Granada (1548-1617), *De Lege et Deo Legislatore*. Here, as in the *De Jure Belli* of Alberic Gentilis, though there is no attempt at a detailed system, yet the true character and general objects of the law of nations are very clearly indicated. Of the workers who were thus engaged in applying the law of nature to the relations of states, the greatest and most successful was Hugo Grotius (1583-1645), who combined profound learning and keen philosophic insight with a large experience in public affairs. In his famous work *De Jure Belli ac Pacis* (1625), starting with the conception of a real and determinable law of nature, he wrought out his principles into a detailed and symmetrical system of rules. The success of the work was rapid and decisive, and upon the foundations thus deeply laid by its great founder international law continues securely to rest. Many of his rules indeed have undergone a process of development, and the growth of civilisation has led to the elaboration of large bodies of new rules to meet new wants and changed circumstances, but the authority of the work as a whole remains unshaken. Among the most interesting legal products of our day are the manuals of the laws of war issued by many civilised states to their officers in the field, and perhaps the most singular feature of these manuals is the number of rules adopted in them direct from Grotius.

It remains now to consider what may be called the secondary sources of this branch of jurisprudence, or the means by which positive international law is defined and declared in the concrete relations of states. In all departments of jurisprudence custom or usage is the earliest form in which positive law declares itself. There is, however, a constant tendency for customs to outlive the circumstances in which they arose: it is thus constantly necessary to test the customary rules by the touch-stone of natural law. Further, many of the recognised rules of international law may be traced to the awards given from time to time by arbitrators, the judgments of mixed courts of prize appointed under treaty, and even to such decisions

as are given in courts corresponding to our Court of Admiralty. The great body of rules comprising the maritime law of nations, together with many fundamental rules in other departments, may be found in the decisions of such international tribunals, and thus rest on authority (precedent) as trustworthy as that which commands the homage of the English lawyer. Of such precedents perhaps the most valuable are those furnished by the decisions given in matters of prize by Sir William Scott, Lord Stowell, in his capacity of judge in the Court of Admiralty. To these judgments, which must always form an important part of a course of study on the law of nations, the American Judge Kent (q.v.) has borne this remarkable testimony: 'There is scarcely a decision in the English prize-courts, on any general question of public right, that has not received the express approbation and sanction of our national courts.' A third factor in the formation of positive international law is express convention among states. While treaties during their subsistence constitute between the parties to them the most direct and authoritative declarations of law, yet it is clear that, being merely contracts, they cannot directly bind by their provisions such states as are not signatories. Nevertheless, a series of treaties between different states containing similar stipulations, or even a single treaty whose provisions have been acceded to and acted upon for a length of time by a large number of nations, may have important effects on consuetudinary law, and in this way may materially affect states which have taken no part in the matter. Thus, although the United States have steadfastly refused to adhere to the Declaration of Paris (1856), yet, if the provisions of that treaty continue to be uniformly acted on by the other powers, the obligation on the United States to conform its practice to the rules there embodied will daily become stronger. Considered as sources of international law, the most important treaties are those which profess to declare the absolute law of nations as understood by the contracting parties, such as those abolishing the slave-trade, or defining the relations of belligerents and neutrals. It is, however, in the scientific interpretation of the law as contained in the writings of the great publicists that the most important of these secondary sources of this branch of jurisprudence is to be found. To render clearer our conceptions of the objects of international law, to draw from isolated facts some general principles, to test these principles by the permanent laws of human nature as revealed by the history of events and by the moral and physical sciences, and, further, to apply admitted principles to new sets of circumstances as they arise—to do this and much more has been the work of a long line of eminent jurists, who are at once the witnesses to the law and the guides of its development. By the formation of the 'Institute of International Law' at Ghent in 1873 an attempt has been made to call into existence a new agency for the development of this branch of jurisprudence.

The subjects of international law are sovereign states. In all branches of jurisprudence life is the source of rights, and, therefore, before a community can be regarded as having the rights and being subject to the obligations of a state, it must be shown to possess the essential attributes of state-existence, or, in other words, it must receive political recognition. To the act of recognition a general character is sometimes communicated by several recognising powers simultaneously presenting to the court of the claimant identic notes of recognition, and at the same time giving to their representatives, already some resident as consuls, their credentials of appointment as ministers. Of such a concerted proceeding between states the recognition

of Roumania in 1880 is a recent example. Roughly, we may say that, according to modern conceptions, a state is a politically autonomous aggregate of human beings, having definite relations to territory, to social existence, to government, and to certain moral ideas, of which the ideas of a historic past and a historic future, and of national unity or common interest are the most dominant and unmistakable. During the nineteenth century the tendency has been to lay stress on nationality—a tendency to whose strength the recent unification of Italy and Germany bears eloquent testimony. Nevertheless, although a political community is composed, as Austro-Hungary now is, of very different races of men, or although it consists internally of a union or federation of smaller communities, yet it may be in the eye of international law a single state, provided the whole is subject to one supreme authority. It is, however, essential that, like every juridical entity, the international state, whether great or small, be separate from every other: its moral and physical activity must be peculiarly its own. The fact that recognition thus implies separate existence at once cuts off all colonies, however important and distant from the parent state, and all communities which, though preserving the organisation of a separate nation, are in practice subject to the rule of another state. The fundamental conception of international jurisprudence is that of the interdependence of states, as opposed to their independence. The fact of the reality of such interdependence is every day becoming clearer with the increase of complexity in the social, commercial, and political ties by which the nations of the world are bound one to another. No state, for example, can administer its own criminal law or execute its own criminal judgments without the continual aid of all other states; and in declaring at its Oxford meeting in 1880 that extradition might take place at all times independently of any contractual obligations, or, in other words, that the right of extradition is a right at common law, the Institute of International Law formally accepted the doctrine of the interdependence of states as a conception fundamental in the law of nations.

Questions of the highest importance may arise when a portion of an existing state rises in rebellion, and, setting up a separate government over a considerable portion of the national territories, tenders to other powers a claim for separate recognition. Here again the question is one of fact, depending on the completeness of the new political and military organisation and the probable extent of the conflict by land and sea. The earliest stage of recognition in such cases usually takes the form of a concession of belligerent rights proceeding either from the opposite party in the war or from neutral states alone, or from both. Such belligerent recognition, while it does not confer the peaceful privileges which belong to the perfect state, yet gives all the rights of public war and binds the states which grant it to all the duties of neutrals. The insurgents thus acquire a recognised status: they may capture the goods of their enemies at sea; they can obtain loans of money, and purchase military and naval materials abroad; their flag is acknowledged; and their revenue laws are respected.

In the eye of international law mankind may be said to fall into three spheres, to each of which belong, of right, at the hands of civilised nations, three distinct stages of recognition—plenary political recognition, partial political recognition, and natural or mere human recognition. The sphere of plenary political recognition extends to all the Christian states of Europe and to those states of North and South America originally colonised by

them which have vindicated their independence. By the treaty of Paris in 1856 Turkey was formally admitted to a participation in the advantages of the public law of Europe and the system of concert attached thereto. In spite, however, of this technical recognition the position of the Ottoman empire is still properly only one of partial recognition, in which sphere are also included Persia, China, Japan, and Siam. In the case of Turkey and these other countries, even when diplomatic relations have been established between them and civilised states, the recognition does not extend to their municipal law, either public or private, except as regards their own citizens within their own frontiers. Within the borders of all these states separate courts are maintained, and to these courts is entrusted the decision of questions between the citizens of the western states resident in these eastern countries. The constitution of these consular courts or mixed tribunals varies considerably in different oriental states, and is in most cases regulated by convention. The practice of Great Britain in this respect is still mainly regulated by the Foreign Jurisdiction Act (6 and 7 Vict. chap. 94). The third sphere, that of mere human recognition, extends to the residue of mankind.

All the subsidiary principles which regulate international relations, so long at least as they continue to be normal, are directly deducible as corollaries from the central doctrine of recognition. Thus, since recognition implies capacity for self-support and self-government, each state has the right to choose whatever form of government best suits the people and to exercise without interference all the powers which it possesses. It may establish, alter, or abolish its own municipal constitution, discover and settle new countries, extend its navigation and fisheries, improve its revenues, arts, agriculture, and commerce, increase its military and naval forces, and develop its national resources by all innocent and lawful means. This fundamental rule that the juridical attitude of states is normally one of mutual confidence, and that the highest political wisdom consists in allowing to each nation entire freedom to manage its own internal affairs and to develop spontaneously its natural resources, negatives the principle of the Balance of Power, now practically obsolete.

As regards proprietary rights, each state is owner of the whole area included within definite boundaries, ascertained by occupation, prescription, or treaty. All ports, bays, mouths of rivers, and a strip of sea three miles in width bordering on the coast-line are included within the territory of the state. In this way each state is enabled more perfectly to carry into effect its maritime laws and customs regulations, to provide for an adequate system of coast defence, and to secure, as long as it remains neutral, immunity from all acts of belligerency between the ships of the enemy. Where, however, part of the territorial waters, so defined, consists of a channel of communication between two portions of the open sea, all vessels of friendly states have the right of free passage. The position of interoceanic canals in international law is not yet quite settled, but the tendency seems to be in favour of the neutralisation of such canals under an international guarantee, so that they may be at all times open to the ships of every nation for the purposes of peaceful passage.

Within its territorial limits each state is entitled to the exclusive power of legislation in respect to the personal rights and civil status of its citizens, and in respect to all real and personal property, whether belonging to citizens or aliens. In recognising the state, other nations recognise its legislative capacity, and consequently are bound, not only to allow it to administer its own municipal law

without interference within its own limits, but also to accept as valid and give effect to the definitions of private rights contained in that municipal law. That part of the municipal legislation of a state which deals with the public relations of citizens is in a different position, and is not recognised as valid within the jurisdiction of other states. Thus, for example, a peer of the United Kingdom carries with him, when he goes abroad, none of the privileges peculiar to his peerage; but as to his private relations—whether he is married or single, a debtor or a creditor, a major or a minor—the continental states in which he is sojourning accept and give effect to what English law says regarding them. So the judgments of the judicial tribunals of a recognised state ought to be, and in practice generally are, accepted without question by foreign states, provided only their validity in the country in which they were pronounced is established. Such foreign judgments are, however, executed within the territory of the recognising state only under the authority and by the order of the native tribunals, and thus the form and manner of execution are exclusively governed by the law of the executing state. With regard to crimes, each state administers its own criminal laws within its territories to foreigners and natives alike. Further than this, each state is bound by the principle of recognition, and consequently by the common law of nations, to aid other states in administering their criminal laws and executing their criminal judgments. Thus the right of each state to demand from other states the surrender of an individual accused of having committed a crime within its territory is a right at common law. To this rule political offences form an exception, inasmuch as they do not partake of the universal character attaching to other crimes. The matter is generally regulated by extradition treaties, in which are usually contained stipulations to the effect that no one will be surrendered unless *prima facie* evidence of his guilt is furnished, and unless adequate assurances are given that the accused will not on that occasion be tried for any offence other than the crime for which he is surrendered. The civil and criminal jurisdiction of a state extends to all its ships on the high-seas or within its territorial waters, and to its public vessels everywhere. When a private ship enters a foreign port, it becomes subject to the 'concurrent jurisdiction' of its own state and of the country in whose territorial waters it lies for the time. Considerable light was thrown upon the exact character and extent of the jurisdiction of a state over that portion of the sea within the three-mile limit by the case of the *Frugonia* (*Regina v. Keyn*, 2 Exch. Div. pp. 202-205). In that case the majority of the court held that, as the law of England stood at that time, the English courts had no jurisdiction over a criminal offence committed by a foreigner on board a foreign ship which was on the open sea but within three miles of the English coasts. In consequence of this decision the Territorial Waters Jurisdiction Act (40 and 41 Viet. chap. 73) was passed, conferring jurisdiction in such cases upon the Courts of Admiralty. To the rule that the jurisdiction of a state extends over all persons and things within its territory the following exceptions are taken—foreign sovereigns and their suites, when visiting a country in their official capacity, diplomatic agents of other states, and public armed forces of a foreign nation passing peacefully through the state territory. The exemption of the citizens of the western European states from the local jurisdiction in eastern countries cannot be considered an exception, inasmuch as these latter countries are only partially recognised, and consequently the principles deduced from plenary recognition are in their case inapplicable.

Private International Law is that department of national law which arises from the fact that there are in the world different territorial jurisdictions possessing different laws. The subjects of this branch of jurisprudence are private individuals, and its rules are administered by municipal courts. The majority of the relations in which human beings stand to each other are in their nature universal, and entirely independent of the states to which the parties belong. Thus an individual may possess real property in a state other than that of his domicile, or he may enter into a contract or execute a testament in a country different from either. As, in general, each of these countries is governed by a distinct system of laws, it is frequently a question under which system the particular relations fall. In the event of an action becoming necessary, is he to appeal to the municipal laws of his native country or domicile, or to that of the place in which the property is situated, or to that in which the contract was entered into, or in which the testament was executed? The whole of the doctrines of private international law accordingly resolve themselves into the single doctrine of the localisation of such legal relations. This branch of law determines no legal relations whatever; it simply says by what system they shall be determined. It is a doctrine of jurisdiction, and nothing more. The collection of rules for thus determining by what system of municipal law each legal relation is governed was usually, till recently, known as the 'conflict of laws'—a title justly censured as expressing a limited and unsound view of this branch of jurisprudence.

According to the famous rules of Foelix and Huber, which were long accepted as the fundamental propositions on which private international law was founded, all the effects which foreign laws can produce within the territory of any nation depend absolutely on the consent of that nation, either express or tacit. The sole foundation for the whole system was found in the voluntary and reciprocal good-will of nations (*comitas gentium*). After being abandoned by the majority of continental jurists, this view was formally repudiated by the Institute of International Law at Geneva in 1874. The whole principle of this branch of law is nothing more than a direct corollary from the doctrine of recognition. The right and duty of mutual confidence involved in the doctrine of recognition imply, as we have seen, the acceptance and enforcement by the recognising state of the definitions which the recognised state may have imposed on legal relations—and this, as a rule, even when the definitions so imposed differ from those which are applied to the same legal relations when existing among its own citizens. In this aspect private international law rests not upon the right of the state which concedes it, but on that of the state to which it is conceded.

The increasing intercourse between individuals of different nations gives a growing importance to the interests affected by this branch of law—the rules being accepted and enforced by the various states as part and parcel of their local law. The rights and obligations which result to persons from the possession of immovables are entirely regulated by the law of the country where the immovable subjects are situated. This *lex loci rei sitæ*, as it is called, determines, even in the case of an alien proprietor, all questions relating to the acquisition of immovables, whether by sale or prescription, to feu-duties, to letting, hiring, and mortgaging, working of mines and minerals, servitudes, and to all taxes and public burdens. The law of the place where real property is situated in short governs exclusively as to the tenure, the title, and the descent of such property. In England and America

the *lex loci rei sita* is also applied to determine the legal capacity of the alien proprietor, in so far as depends on his personal status, for example, the age at which he can acquire, alienate, or succeed to immovables. In Scotland and in most continental countries the capacity to acquire or alienate immovable property is regulated by the law of the domicile of the owner, by which all matters relating to status are exclusively governed. In nearly all European countries the rule long obtained that the tenure of immovable property was only possible to a foreigner on the condition of political naturalisation. In almost all states this rule has now been relaxed; and in Britain it has been entirely departed from under the Naturalisation Act of 1870 (33, 34 Viet. chap. 14, sect. 2), which provides: 'Real and personal property of every description may be taken, acquired, held, and disposed of by an alien in the same manner in all respects as by a natural-born British subject; and a title to real and personal property of every description may be derived through, from, or in succession to an alien, in the same manner in all respects as through, from, or in succession to a natural-born British subject.' On the other hand, all movable and personal property is governed by the law of the domicile (*lex domicilii*). Domicile is defined by Westlake to be the 'legal conception of residence,' and is made up of various elements of birth, citizenship, &c. This law of the domicile also regulates all questions regarding personal status, legitimacy, and succession to movable property. If a question arises about a contract, its validity and interpretation are determined by the law of the country in which the contract was entered into (*lex loci contractus*). Thus, if a marriage is valid by the law of the place where it was made, it is, generally speaking, valid everywhere else. Wherever, from the nature of the contract itself, or the law of the place where it is made, or the expressed intention of the parties, the contract is to be executed in another country, everything which concerns its execution is to be determined by the law of that country. Again, all questions as to the admissibility and value of evidence or as to procedure or remedy are determined by the laws in force at the forum in which an action is raised (*lex fori*). If a contract made in one country is attempted to be enforced in the judicial tribunals of another, all questions of prescription are to be determined by the law of the state where the suit is pending. Such at least was the view taken in the famous case *Don c. Lippmann*, though Savigny, Westlake, Bar, and others argue strongly that this is a matter which ought to be decided by the law of the place where the contract was made.

Interpleader is a form of process in the English courts intended for the protection of a defendant who claims no interest in the subject-matter of a suit, while at the same time he has reason to know that the plaintiff's title is disputed by some other claimant. In such a case the defendant may apply to a judge, who will order the plaintiff and the other claimant to appear and interplead. An application of this kind may now be made in any action in the High Court. Special protection is given to sheriffs, &c. when goods taken in execution are claimed by a third party.

Interpretation. See EXEGESIS.

Interpreter. See DRAGMAN.

Interval, in Music, is the difference of pitch between any two musical tones. Since pitch depends upon the vibration-frequencies, the relation between any two pitches is the numerical ratio between the two vibration-frequencies; and all pairs of tones within which the frequencies have the same ratios present equal intervals. The interval between any two tones, whether chosen or heard at random, is thus expressible as an arithmetical ratio; but musically it is only certain intervals which are recognised as being musical intervals, and what these are depends upon the Scale (q.v.) which is in use. Among the European nations and those of European descent the diatonic scale is employed; and this, when unmodified by Temperament (q.v.), presents the ratios given under Harmonics (q.v.). Within such a scale the various intervals that may be found are (C being taken to represent the keynote of the scale) minor second (= E—F or B—C') = 16/15; grave major second (= D—E or G—A) = 10/9; major second (= C—D, F—G, A—B) = 9/8; grave minor third (= D—F) = 32/27; minor third (= E—G, A—C', B—D') = 6/5; major third (= C—E, F—A, or G—B) = 5/4; perfect fourth (= C—F, D—G, E—A, G—C', or B—E') = 4/3; acute fourth (= A—D') = 27/20; acute augmented fourth (= F—B) = 45/32; grave diminished fifth (= B—F') = 64/45; grave fifth (= D—A) = 40/27; perfect fifth (= C—G, E—B, F—C', G—D', A—E') = 3/2; minor sixth (E—C', A—F', B—G') = 8/5; major sixth (= C—A, D—B, G—E') = 5/3; acute major sixth (= F—D') = 27/16; grave minor seventh (D—C', G—F', B—A') = 16/9; minor seventh (E—D', A—G') = 9/5; seventh (C—B, F—E') = 15/8; octave (C—C', D—D', &c.) = 2/1. By taking various notes of the diatonic scale as starting-points, and measuring known intervals from these, we arrive at intermediate notes of the scale, of which the following are examples, the vibration-ratios being given with reference to C':

	Vibration-ratios.
C; minor third below E.	25/24 = 1.0416
D \flat (as A; D; c; A \flat ; D \flat).	27/25 = 1.0800
D \sharp ; minor second below E.	75/64 = 1.1672
E \sharp ; minor third above C.	6/5 = 1.2000
A \flat ; minor sixth above C.	8/5 = 1.6000
B \flat ; minor seventh above C.	9/5 = 1.8000
B \sharp ; 3 major thirds above C.	125/64 = 1.9531

The difference of pitch between C and C \sharp or between D and D \flat is frequently called a semitone, and an interval increased or diminished by a semitone is said to be augmented or diminished. This applies especially to the interval of a fourth or a fifth,

which with the octave are said to be perfect, because any augmentation or diminution mars their consonance. The major sixth or third may however be diminished to a 'minor' sixth or third without destroying the consonance; and the term 'minor' is also applied to the diminished second or seventh. The octave begins a new series, and thus the 'ninth' is the octave of the second, and so forth. For further discussion of the musical nomenclature, which is somewhat unsettled, see article 'Interval' in Grove's *Dictionary of Music and Musicians*; and for a numerical table of the various intermediate tones within the scale, see Daniell's *Principles of Physics*, 2d ed. pp. 390-91.

Intestacy. the state of a person who has died without testing—i.e. without leaving a will. If no will, or deed equivalent to a will, is executed, or if a will executed is invalid from defect of form, then an intestacy occurs, and the law provides an heir or next of kin, in lieu of the owner himself doing so. See HEIR.

Intestines. a part of the digestive system, divided into the smaller intestine (comprising duodenum, jejunum, and ileum) and the greater intestine. See DIGESTION, Vol. III. pp. 814, 815; GUT; and for Diseases, see CONSTIPATION, DIARRHŒA, DYSENTERY, ENTERITIS, PERITONITIS, &c.

Intimidation. See THREAT.

Intonation. The opening phrase of any plain-song melody, sung usually either by the officiating priest alone, or by one or more selected choristers. The term is most commonly applied to the first member (consisting of two or three notes) of a Gregorian Psalm tone, the other members of it being the *dominant* (or reciting-note), the *mediation*, and the *ending*. Its use is confined usually to the first verse of the psalm or canticle, except in the case of the *Magnificat*, *Benedictus*, and *Venite*, to give greater solemnity to which it recurs in each successive verse.

Intoning. a modern popular term for the utterance in musical recitative of the versicles, responses, collects, &c. of the Anglican Liturgy. This recitative consists mainly of a single sustained note, or *monotone*, but may be varied by the introduction of certain simple inflections, which have the sanction of more or less prevalent custom or tradition. Of these a full account may be found in various choral books—e.g. in Doran and Nottingham's *Choir Directory of Plain-song*, Doran and Thompson's *Ritual Music of the Altar* (both published by Novello), and in *Notes on Ceremonial* (Pickering).

Such musical recitative in vocal prayer is undoubtedly very ancient, and its employment in Christian worship is, in fact, an inheritance from the Synagogue, where it may be heard still. It obtains equally among Mohammedans, American Indians, South Sea Islanders, and the great majority of barbarous nations, and would seem to be the outcome of an instinctive feeling that the familiarity of our colloquial tones of voice is out of keeping with the reverence that befits human intercourse with Deity. Whatever may be said for or against the practice elsewhere, there can be no doubt that in our cathedrals and larger sacred buildings an audible utterance would without it be far less easily attainable.

Intoxication. This term is applied to the condition brought about by an overdose of alcohol. The symptoms induced vary a good deal according to the rapidity with which the alcohol is drunk and absorbed into the blood, and also according to the form—spirits, wine, or beer—in which it is taken. If they are swallowed rapidly in large quantities the symptoms are those of a narcotic poison. See ALCOHOL, ALCOHOLISM, POISON.

Intoxication, or drunkenness, is, in point of law, no excuse for any wrong done by the drunken party. Crimes which are committed in a state of drunkenness are punishable in the same way as if the actor were sober, though it is discretionary in the court to mitigate the sentence. A contract made when the parties, or either of them, are in a state of complete incapacity from intoxication may be made void. So it is when one of the parties is intoxicated, and a sober person induces his consent by fraud. Thus, if goods are sold to a person so drunk that he does not know what he is doing, the purchase may be repudiated as soon as the drunk man becomes sober. Unless he does so immediately on coming to his senses, however, the contract will stand. The drunk man, in short, may either repudiate or enforce the bargain when he comes to his senses. The mere act or state of drunkenness, when privately indulged in, is not an offence against the law; but if it be shown in public it may become so. Every person found drunk in a highway or public place, or in a licensed house, is liable to a penalty of ten shillings; and on a second offence within twelve months, to twenty shillings, and on a third offence within twelve months, to forty shillings. To be drunk and riotous, or be drunk while in charge of a horse or carriage, or of a gun, is punishable with a fine of twenty shillings, or imprisonment for one month. Local acts also often impose other penalties. In Scotland several ancient statutes were passed against drunkenness, which, however, are in desuetude. In many local police acts a penalty is imposed on drunkenness in the streets.

Intransigents, or INTRANSIGENTES (*Irreconcilables*), a name sometimes given to the extreme political parties opposed to the existing government in Italy, Spain, and France; as, for instance, the revolutionary communists in Spain in 1873. For the connection of these last with the anarchistic party, see INTERNATIONAL.

Intrenchments. See ENTRENCHMENTS.

Introduction (Ital. *introduzione*), in Music, is a kind of preface or prelude to a following movement. Formerly the introduction was only to be found in large musical works, such as symphonies, overtures, oratorios, &c.; but now it is found in every rondo, fantasia, polonaise, waltz, &c., on the principle that it is considered abrupt to begin all at once, without preparing the audience for what is to come. In earlier operas introduction is applied to the piece of music with which they begin, and which immediately follows the overture. In some cases the overture and introduction are united, the composition going on without any formal pause, as in Gluck's *Iphigénie en Tauride*, Mozart's *Idoménée* and *Don Giovanni*. Overtures themselves are frequently commenced by an introduction, as in Beethoven's *Egmont* and *Leonora*, Nos. 2 and 3, and Weber's *Freischütz*; and *Oberon* overtures. The majority of Wagner's operas commence with an introduction (*Vorspiel* or *Einführung*), a short one being also prefaced to the second and third acts. The introductions are also important and characteristic parts of several of the symphonies of Beethoven and Schumann.

Introit, in the Roman Catholic Church, an anthem sung at the beginning of the mass, immediately after the *Congitor*, and when the priest has ascended to the altar. It consists of an antiphon, Gloria Patri, and usually part of a psalm; but other passages of Scripture are used, while a few introits in the present Missal are taken from uninspired writers, and one (Whit-sunday) is from 2d Esdras. The introduction of introits is ascribed to Gregory the Great (595), or perhaps to Celestine (423). In the first prayer-book of Edward VI.

an introit is prefixed to each collect, consisting of a psalm to be sung after the opening prayer in the communion office.

Intromission. in Scotch law, is the assumption of authority to deal with another's property. It is divided into legal and vicious. Legal intromission is where the party is expressly or impliedly authorised, either by judgment or deed, to interfere, as by drawing the rents or getting in debts. Vicious intromission is where an heir or next of kin, without any authority, interferes with a deceased person's estate; as, for example, where a person not named by a will, or without the authority of any will, collects the property of the deceased person as if he were regularly appointed. By so doing the vicious intromitter incurs the responsibility of paying all the debts of the deceased. The viciousity, however, may be taken off by the intromitter being regularly confirmed executor. The corresponding phrase in England to a vicious intromitter is an *executor de son tort*.

Intuition. See COMMON SENSE, A PRIORI, LOCKE, REID, ETHICS, PSYCHOLOGY.

Intus-susception. or INVAGINATION, is the term applied to the partial displacement of the bowel in which one portion of it passes into the portion immediately adjacent to it, just as one part of the finger of a glove is sometimes pulled into an adjacent part in the act of withdrawing the hand. In this case the contained portion of intestine is liable to be nipped and strangulated by the portion which contains it, and all the danger of Hernia (q.v.) results, with far less chance of successful interference on the part of the surgeon or physician. It is one of the most frequent and fatal causes of obstruction of the bowels in children, but less common in adults. The extent of the intus-susception may vary from a few lines to a foot or more. Even when inflammation is set up, the affection, although in the highest degree perilous, is not of necessity fatal. The invaginated portion mortifies and sloughs, while adhesion is established between the peritoneal surfaces of the upper and lower portions at their place of junction, so that the continuity of the tube is preserved, although a large portion may be destroyed. If the patient is strong enough to bear the shock of the inflammation, gangrene, sloughing, &c., a complete recovery may ensue, though such a termination is rare. In the early stage the normal condition may often be restored by large enemata of air or water. Of late some success has attended operation where simple measures have failed. For Volvulus, see COLIC.

Inulin, a vegetable principle, isomeric with starch, derived from Elecampane (q.v.).

Invalides. HOTEL DES. See PARIS.

Invaliding signifies the return home, or to a more healthy climate, of soldiers or sailors who have been rendered incapable of active duty by wounds or the severity of foreign service. The man invalided returns to his duty if his health is sufficiently restored to justify the step, otherwise he is discharged as 'medically unfit.'

Invention. See PATENT.

Inventions and Discoveries. The following list purports to give only a few of the more important inventions and discoveries, chiefly such as have exercised a determining influence upon the civilisation of the world. The principal geographical discoveries have been already discussed under GEOGRAPHY. For other information, see Beckmann's *History of Inventions, Discoveries, and Origins* (new ed. 1888).

Mariner's Compass, invented in Europe in the 12th century, although known and used for centuries previously in China.
Gunpowder, by Schwarz about 1320 (see GUNPOWDER).
Printing, by Johann Gutenberg, about 1440 (see PRINTING).
Copernican System, in 1543 by Copernicus (q.v.).
Microscope, by Hans and Zacharias Janssen, or Zausz of Middelburg, about 1590.
Circulation of the Blood, by Harvey, in 1616.
Electricity, name invented and knowledge of advanced by W. Gilbert, 1651; induced electricity discovered in 1831 and its relation to magnetism shown in 1819 by Oersted and in 1835 by Faraday.
Law of Gravitation, by Newton, 1682.
Steam-engine, by Newcomen in 1705, and by Watt in 1766.
Pianoforte, by Cristofori of Florence, before 1720.
Clock, used in Europe in the 11th century. Chronometer, by John Harrison, 1762.
Spinning-jenny, by Hargreaves, in 1767.
Balloons used by Montgolfier, 1782-83.
Weaving-loom, by Cartwright, in 1785.
Gas-lighting, by William Murdoch, in 1792, at Redruth in Cornwall.
Vaccination, by Jenner, in 1796.
Steamboat proved practically useful, by Fulton on the Hudson, 1807.
Locomotive on railway, by George Stephenson, in 1814.
Moor's safety-lamp, by Davy, in 1816.
Photography, by Nièpce, in 1825.
Electric Telegraph, by Morse, 1835, and by Wheatstone and Cooke, 1834-37 (see TELEGRAPH).
Penny Postage, by Sir Rowland Hill, 1840.
Sewing-machine, by Elias Howe, 1841.
Chloroform, used as an anæsthetic by Simpson in 1848.
Evolution Theory, by Darwin and Wallace, in 1858.
Spectrum Analysis, by Kirchhoff and Bunsen, 1860.
Telephone (q.v.) in 1800-76.
Photograph, by Edison, in 1889.
Röntgen Rays, by Röntgen, at Würzburg, in 1895.
Argon (1895), followed by Krypton, Neon, Metargon, Coronium, Mollium (1898).

Inventory. in England a list of a deceased person's effects made by an executor. In Scotland it is also used in reference to the property of an infant, pupil, or minor whose estate is under the care of a guardian, tutor, curator, or judicial factor. In Scotland it is also used in connection with the various pleadings and deeds and documents produced or used in a suit or action, then called an inventory of process. So as to an inventory of titles—i.e. the titles of an estate shown to a purchaser.

Inveraray, the county town of Argyllshire, is picturesquely seated on the north-west shore of Loch Fyne, 16 miles SSW. of Dalnally station, and 45 NNW. of Greenock (*viz.* Loch Eck). Removed to its present site in 1742, it has a sculptured stone cross from Iona (*c.* 1400), and an obelisk to the memory of seventeen Campbells, executed here without trial in 1685 for their share in Argyll's expedition. Inveraray Castle, the seat of the Duke of Argyll (q.v.), was rebuilt in 1744-61. A royal burgh since 1648, Inveraray with Ayr, &c. returns a member to parliament. Pop. (1841) 1233; (1891) 743.

Invercargill, a town in the province of Otago, New Zealand, capital of the county of Southland, stands on an estuary called the New River Harbour, 139 miles by rail SW. of Dunedin. It is regularly built, with fine wide streets, gas, and steam trams, and is unusually well provided with public parks. Besides the government buildings and schools and churches, it possesses an excellent athænaum and a hospital. There are some thirty sawmills in and around the town, besides foundries, steam flour-mills, breweries, and manufactures of boots, bacon, cordials, &c. There are extensive meat-freezing works at the mouth of the estuary, and much Southland mutton is now sent to England; other exports from Invercargill are wool, grain, cheese, and timber. Pop. 7962.

Inverkeithing, a royal burgh of Fife, at the head of Inverkeithing Bay, 13 miles WNW. of Edinburgh. With Stirling, &c., it returns one member to parliament. Pop. 1676.

Inverlochty, a ruined castle of Inverness-shire, 2 miles NE. of Fort William, near which on

Sunday, 2d February 1645, Montrose completely routed his rival, Argyll.

Inverness, the county town of Inverness-shire, and capital of the northern Highlands, stands on the Ness, near its mouth in the Moray Firth and the north-east end of the Caledonian Canal, 108 miles by rail WNW. of Aberdeen, 144 NNW. of Perth, and 190 NNW. of Edinburgh. Its wooded environs, hemmed in by hills (Tounahurich, 223 feet; Torvean, 300; Craigphadrick, 130; Dunean, 940, &c.), form a picturesque and interesting landscape. Visited by Columba (q.v.) about 565, and by Malcolm Canmore made the seat of a royal castle, by Cromwell of a citadel (1652), Inverness has a wealth of memories. It was garrisoned by the English in 1296; in 1441 was burned by Donald of the Isles on his way to Harlaw; and figures repeatedly in the history of the Stuarts, down to their final overthrow at Culloden, hard by. In front of the Scots-Flemish town-hall (1882), protected now by a fountain, is the Clach-na-Cudain, or 'stone of the tubs,' the palladium of the burgh. The Episcopal cathedral (1867) of the united diocese of Moray, Ross, and Caithness is a fine Decorated edifice; and other features of the place are the county hall (1835) on the site of the castle, the infirmary (1804), the lunatic asylum (1860), the royal academy (1792), the barracks (1884), the main suspension bridge (1855), and the Islands, a favourite promenade. Malting, thread-making, and bleaching have given place to woollen manufacture, shipbuilding, distilling, &c., with considerable shipping and commerce, the harbour having been much improved in 1847. The great wool fair (established in 1817) is held in July; and the Northern Meeting (1788) in September. A royal burgh since about 1067, Inverness unites with Forres, Fortrose, and Nairn to return one member to parliament. Pop. (1831) 9663; (1881) 17,365; (1891) 29,855, of whom 6356 were Gaelic-speaking, though Inverness still is famous, as in Defoe's and Dr Johnson's day, for the purity of its English. See two books by Fraser Mackintosh (1865-75), Miss Anderson's *Inverness before Railways* (1885), and *Mémorabilia of Inverness* (1887).

Inverness-shire, a Highland county, the largest in Scotland, and larger than any in England but Yorkshire, stretches from sea to sea, and has a total area of 4323 sq. m., of which 1284 belong to the Outer Hebrides—Skye, Harris, North and South Uist, Benbecula, Barra, Raasay, Eigg, St Kilda, and thirty-seven other inhabited islands. The mainland portion, measuring 83 by 55 miles, is intersected NE. and SW. by the Great Glen and the Caledonian Canal (q.v.). It includes Badenoch, Glenroy, and the valley of the Spey on the east; Lochaber on the south; Glenelg, Glengarry, Arasaig, and Moidart on the west; Strathglass on the north; Glenurquhart and Glenmoriston towards the centre. It is truly a 'land of the mountain and the flood,' for it contains Ben Nevis (4406 feet), the highest point in Britain, with twenty-six other summits exceeding 3500 feet, whilst the chief of its rivers are the Spey, Ness, and Beauly, and of ninety good-sized lakes Lochs Ness, Archaig, Shiel, Lochy, Monar, Laggan, and Eriocht. The west coast is indented by salt-water Lochs Hourn, Nevis, and Moidart. The rocks include gneiss, mica-slate, granite, porphyry, and trap; and the most fertile soil in the county rests on the red sandstone in the valley of the Aird, and between the county town and Beauly. Only 4.6 per cent. of the whole area is in cultivation; and 255 sq. m. are under wood, the rest being sheep-walks, deer-forests, moss, and barren heath, valuable only as grouse moors. Sheep, numbering some 700,000, are the principal live-stock; and there are five deer-forests of 50 sq. m. and

upwards. The rivers and lakes afford splendid fishing, and in 1890 the total rental of the shootings, deer-forests, and fishings of Inverness-shire was £86,902. The land is mostly divided among eighty-nine proprietors, eight holding each above 100,000 acres. The county returns one member to parliament. Inverness is its only town of any size; Kingussie and Fort William, though police burghs, are mere villages, as also are Beauly, Fort Augustus, and Portree. Pop. (1801) 72,672; (1841) 97,799; (1881) 90,454; (1891) 90,121, less than 21 inhabitants per square mile. See articles on the chief islands, lakes, &c., as well as on HIGHLANDS, HEBRIDES, CULLODEN, DEER-FORESTS, GLENROY, and FOYERS.

Inversion, in Music, is of three kinds. (1) Of a chord, when any other of its component notes than the root is placed lowest (see HARMONY). (2) Of an interval (within the octave), when the lower note is transposed an octave higher, or *vice versa*. To find what an interval becomes by inversion, subtract the figure denoting it from the figure nine; thus, a second inverted becomes a seventh, a third becomes a sixth, &c. In this change major intervals become minor, augmented intervals become diminished, and *vice versa*. (3) Of a subject or theme, when it is imitated in contrary motion—i.e. the melody progresses by the same intervals as the original theme, but ascends or descends always in a contrary direction. This is a frequent device in fugues and other contrapuntal music.

Invertebrata, a collective title for those animals which agree in *not* exhibiting the characteristics of Vertebrates—viz. a dorsal nerve cord, a dorsal median supporting axis or notochord, respiratory clefts on the pharynx, a ventral heart, and eyes arising for the most part as out-growths of the brain. But the dividing line is no longer so clear as it once seemed, for not only are Ascidians or Tunicata recognised as degenerate Vertebrate or Chordate animals, but several 'worm' types, among Nemerteans and Chaetopods, approach Vertebrates in some of their characters, while Balanoglossus (q.v.) and Cephalodiscus (q.v.) are so near the boundary line that they are usually called Hemi-chordata or half Vertebrates.

Invertebrate animals are first divided into (1) Protozoa—uni-cellular—and (2) Metazoa—multi-cellular. The latter then fall into two distinct divisions: (*a*) without body-cavities—Sponges and Coelenterates—and (*b*) with more or less of a body-cavity—the Coelomata. Among the latter starfish, &c. (without including Vertebrates), the Echinoderms, the Arthropods (Crustaceans, Insects, &c.), and the Molluscs (bivalves, snails, cuttle-fish), and finally a great mob of 'worms,' divisible into many classes—Flat-worms, Nemerteans, Round-worms, Chaetopods, &c. have to be distinguished. See VERTEBRATA, and separate articles.

Inverurie, a royal burgh of Aberdeenshire, at the influx of the Urie to the Don, 16 miles NW. of Aberdeen. With Elgin, &c. it returns one member to parliament. Pop. 3165.

Investiture, in feudal and ecclesiastical history, means the act of giving corporal possession of a manor, office, or benefice, accompanied by a certain ceremonial, such as the delivery of a branch, a banner, or an instrument of office, more or less designed to signify the power or authority which it is supposed to convey. The contest about ecclesiastical investitures is interwoven with the whole course of medieval history. The system of feudal tenure had become so universal that it affected even the land held by ecclesiastics. Accordingly, ecclesiastics who, in virtue of the ecclesiastical office which they held,

came into possession of lands began to be regarded as becoming by the very fact feudatory to the suzerain of these lands; and the suzerains thought themselves entitled to claim, in reference to these personages, the same rights which they enjoyed over the other feudatories of their domains. Among these rights was that of granting solemn investiture. Now, in the case of bishops, abbots, and other church dignitaries the form of investiture consisted in the delivery of a pastoral staff or crozier, and the placing a ring upon the finger; and as these badges of office were emblematic—the one of the spiritual care of souls, the other of the espousals, as it were, between the pastor and his church or monastery—the assumption of this right by the lay suzerains became a subject of constant and angry complaint on the part of the church. On the part of the suzerains it was replied that they did not claim to grant by this rite the spiritual powers of the office, their function being solely to grant possession of its temporalities. But the church party urged that the ceremonial in itself involved the granting of spiritual powers; inasmuch that, in order to prevent the clergy from electing to a see when vacant, it was the practice of the emperors to take possession of the crozier and ring, until it should be their own pleasure to grant investiture to their favourites. The disfavour in which the practice had long been held found its most energetic expression in the person of Gregory VII., who having, in the year 1074, enacted most stringent measures for the repression of simony, proceeded, in 1075, to condemn, under excommunication, the practice of investiture, as almost necessarily connected with simony, or leading to it. But a pope of the same century, Urban II., went further, and (1095) absolutely and entirely forbade not alone lay investiture, but the taking of an oath of fealty to a lay suzerain by an ecclesiastic. In the 12th century the pope, Pascal II., agreed to surrender the possessions and royalties of the church on condition of the emperor (Henry V.) giving up his claim to investiture. This treaty, however, never had any practical effect; nor was the contest finally adjusted until the celebrated concordat of Worms in 1122, in which the emperor agreed to give up the form of investiture *with the ring and pastoral staff*, to grant to the clergy the right of free elections, and to restore all the possessions of the Church of Rome which had been seized either by himself or by his father; while the pope, on his part, consented that the elections should be held in the presence of the emperor or his official, but with a right of appeal to the provincial synod; that investiture might be given by the emperor, but *only by the touch of the sceptre*; and that the bishops and other church dignitaries should faithfully discharge all the feudal duties which belonged to their principality. See CHURCH OF ENGLAND, FEUDALISM.

Invincibles. See FENIANS, CAVENDISH.

Involucere. In a shortened Inflorescence (q.v.), such as the umbel, the bracts, unless suppressed, are necessarily close together, and form an apparent whorl (but really a close spiral) around the group of pedicels. This is the involucre. In compound umbels the whorl of bracts of the secondary umbel is therefore a secondary involucre, and is commonly called an involucre. In composites the crowded whorl of green leaves immediately outside the capitulum, which the non-botanist mistakes for a calyx, is constantly termed the involucre, but no less inaccurately, since here the true bracts are those of the separate florets, and occur on the surface of the capitulum itself (e.g. *Finnia*, Sunflower, &c.). The composite 'involucre' is therefore merely derived from those leaves of the axis below the capitulum which remain green and vegetative since bearing

no florets in their axils. In Scabions (q.v.) the true bract of each floret in the capitulum unites as a sheath around the ovary, and is also known as the involucre. Here, again, we have a regrettable use of terms, themselves hardly necessary, in two distinct senses.

Involute. See EVOLUTE.

Involution and Evolution are two operations the converse of each other. The object of the first is to raise a number to any power, which is effected by continuously multiplying the number by itself till the number of factors is equal to the number designating the power. Thus, 2 raised to the third power is $2 \times 2 \times 2$, or 8; 7 raised to the fourth power is $7 \times 7 \times 7 \times 7$, or 2401, &c. Evolution, on the other hand, is the extraction of a root of any number—that is, it is a method for discovering *what* number, when raised to a certain power, will give a certain known number. Thus, the square root of 64 is 8—that is, 8 is the number which, raised to the second power, will give 64; 3 is the fourth root of 81—that is, 3 raised to the fourth power is 81; and so on. The symbols expressive of the two operations are as follow: 5^3 means that 5 is to be raised to the third power; $(7^2)^5$ means that the square or second power of 7 is to be raised to the fifth power; $\sqrt[9]{9}$ or $\sqrt[9]{9}$ signifies that the extraction of the second or square root of 9 is required; $\sqrt[256]{256}$ or $256^{\frac{1}{256}}$, that the fourth root of 256 is to be extracted; and so on. Involution and evolution, like multiplication and division, or differentiation and integration, differ in the extent of their application; the former, or direct operation, can always be completed, while there are numberless cases in which the latter fails to express the result with perfect accuracy.

Io, the daughter of Inachus, king of Argos, was beloved by Zeus, and, transformed through fear of Hera's jealousy into a cow, had many wanderings. See ARGUS.

Iodine (sym. I, equiv. 127) is one of the four non-metallic elements. It was discovered in 1811, by Courtois, in the waste liquors produced in the manufacture of carbonate of soda from the ashes of seaweeds. A few years later Gay-Lussac discovered that it was a simple elementary body. While it is still obtained from the half-fused ash of dried seaweeds, which is known in Britain as Kelp (q.v.), it is much more largely prepared in South America from the iodate of sodium, which is found associated with nitrate of sodium in the native Chili saltpetre.

In small quantity, and usually in combination with sodium, magnesium, or calcium, iodine is very widely diffused over the earth's surface. It exists in sea-water, in marine animals and plants, and in certain mineral springs. It is also found in several minerals, as, for example, in certain Mexican silver ores, in Silesian zinc ores, in phosphorite from the Upper Palatinate, and in coal.

At ordinary temperatures it usually occurs in solid, dark-gray, glistening scales; it is, however, crystallisable, and sometimes appears as an octahedron with a rhombic base. It is soft, and admits readily of trituration, has the high specific gravity of 4.95, and evolves a peculiar and disagreeable odour, which indicates its great volatility. It fuses at 225° (107° C.), and at about 350° (177° C.) it boils, and is converted into the purple vapour to which it owes its name (Gr. *iodēs*, 'violet-like'); it has an acrid taste, and communicates a brownish-yellow colour to the skin. It is very slightly soluble in water, but dissolves readily in watery solutions of iodide of potassium and of hydriodic acid, and in alcohol and ether. Iodine vapour is the heaviest of known vapours, its specific gravity

compared with air as unity being 8.716. It combines directly with phosphorus, sulphur, and the metals. Its behaviour with hydrogen is analogous to that of chlorine and bromine (see HYDROCHLORIC ACID), but its affinities are weaker than those of the last named elements. It likewise combines with numerous organic substances, and the compound which it forms with starch is of such an intense blue colour that a solution of starch forms the best test for the presence of free iodine. By means of this test one part of iodine may be detected when dissolved in one million parts of water.

With hydrogen iodine forms one compound, *hydriodic acid* (HI), a colourless, pungent acid gas, which in most respects is analogous with hydrochloric acid. It may be obtained by gently heating a mixture of amorphous phosphorus, iodine, and water. The soluble iodides of the metals may be obtained by the direct combination of hydriodic acid with the metallic oxides, the resulting compounds being the metallic iodide and water. Some of these iodides are of extreme brilliancy—e.g. the iodide of mercury, scarlet; the iodide of lead, yellow; and others are of great value in medicine. Amongst the latter must be especially mentioned iodide of potassium, iodide of iron, and the iodides of mercury.

Iodide of potassium is one of the most important medicines in the pharmacopœia. It crystallises in colourless cubes, which are sometimes clear, but usually have an opaque whitish appearance, and are soluble in water and spirit. It is decomposed and the iodine set free by chlorine, bromine, fuming nitric acid, and Ozone (q.v.). Iodide of iron is formed by shaking iron wire or filings in a closed vessel with four times the weight of iodine suspended in water. There are two iodides of mercury—viz. the green subiodide (HI₂) and the red iodide (HI₃). There are several well-defined compounds of iodine and oxygen, but they are of no special interest.

The preparations of iodine are employed extensively in medicine and in Photography (q.v.). Iodine itself or its compounds may give rise to the symptoms known as *iodism*; most commonly running at the nose and eyes, with headache and sore throat; sometimes irritation of the intestinal canal, either alone or combined with the other symptoms. In the case of the iodine compounds these unpleasant results usually cease if the dose be increased.

Iodine and its compounds increase the activity of the absorbent system generally, and are useful in enlargement of the glands connected with that system (lymphatic glands, thyroid, spleen), and wherever absorption is deficient (hypertrophy of breasts, uterus, &c.); indolent inflammatory exudation in any organ). But they are perhaps of the greatest value in certain forms of chronic rheumatism, certain stages of syphilis, in serofulous conditions generally, and in chronic poisoning by mercury and lead. In the last case they set free the metals from insoluble compounds in the tissues, and allow them to be eliminated from the body in solution in the urine.

Iodine is chiefly prescribed internally in combination, as iodide of potassium, iodide of iron, especially in strumous cases, and red iodide of mercury in syphilis. Free iodine is very apt to cause irritation of the intestinal canal, and can in general only be employed in small doses. But as an external application, in the form of ointment, tincture, or liniment, it is extensively used and is very valuable. It acts as a para-siticide in ringworm, removes muscular pains, and promotes the absorption of exudations and the subduing of chronic inflammations. In large doses iodine and most of

the iodides act as irritant poisons; but very few fatal cases are on record. In the event of poisoning with the tincture of iodine the first point is to evacuate the stomach. See POISONS.

Iodoform (CHI₃) is a lemon-yellow crystalline substance, having a saffron-like odour and an unpleasant iodine-like taste. Its odour is most persistent, and can hardly be removed. It is of interest as having a composition similar to that of Chloroform (q.v.), from which it only differs in having iodine in the place of chlorine. It may be prepared by the action of iodine on alcohol in the presence of carbonate of potash. It is almost insoluble in water, but dissolves in alcohol, ether, and chloroform. It is readily volatile when heated, and in the form of vapour has anæsthetic properties. It is employed externally as an application to painful ulcers, and it often gives relief in uterine cancer. In the form of iodoform gauze it is used in antiseptic surgery.

Iolite. See CORDIERITE.

Iona, the most famous of the Hebrides, 1½ mile W. of the south-western extremity of Mull. Its modern name is believed to have originated in a mistaken reading of *n* for *u*; the word in the oldest manuscripts being clearly written *Iona*. From the 6th century to the 17th century the island was most generally called *I. Ii, Ia, Ia, Ea, Iy, Ii, Hii, Hii, Hu, Y,* or *Yi*—that is, simply, 'the island'; or *Islandkill, I-Columb-Kille*, or *Hii-Colum-Kille*—that is, 'the island of Columba of the church.' It is 3½ miles long, and 1½ mile broad. Its area, computed by Bede at 'five families' (or 'five hides of land,' as the passage is rendered in the Anglo-Saxon Chronicle), is 3½ sq. m., or 2264 acres, of which rather more than a fourth part is under tillage. The soil is naturally fruitful; its fertility was regarded as miraculous in the dark ages, and, no doubt, led to the early occupation of Iona. Dunii, the highest point of the island, is 327 feet above the sea-level. Pop. 247.

Its history begins in the year 563, when St Columba (q.v.), leaving the shores of Ireland, landed upon Iona with twelve disciples. Having obtained a grant of the island, he built upon it a monastery, which was long regarded as the mother-church of the Picts, and was venerated not only among the Scots of Britain and Ireland, but among the Angles of the north of England, who owed their conversion to the self-denying missionaries of Iona. From the end of the 6th to the end of the 8th century Iona was scarcely second to any monastery in the British Isles; and it was this brilliant era of its annals which rose in Johnson's mind when he described it as 'that illustrious island which was once the luminary of the Caledonian regions, whence savage clans and roving barbarians derived the benefits of knowledge and the blessings of religion.' But neither piety nor learning availed to save it from the ravages of the fierce and heathen Norsemen. They burned it in 795 and again in 802. Its 'family' (as the monks were called) of sixty-eight persons were martyred in 806. A second martyrdom, in 825, is the subject of a contemporary Latin poem by Walafrius Strabus. On the Christmas evening of 986 the island was again wasted by the Norsemen, who slew the abbot and fifteen of his monks. Towards the end of the next century the monastery was repaired by St Margaret, the queen of Malcolm Canmore. It was visited in 1097 by King Magnus Barefoot of Norway. It was now part of that kingdom, and so fell under the ecclesiastical jurisdiction of the Bishop of Man and the Archbishop of Trondheim. In 1203 a Benedictine monastery was founded here, and a Benedictine (afterwards Augustinian) nunnery.

In 1506 Iona became the seat of the Scottish Bishop of the Isles, the abbey church being his cathedral, and the monks his chapter.

No building now remains on the island which can claim to have sheltered St. Columba or his disciples. The most ancient ruins are the Laith-ricehan, or Foundations, in a little bay to the west of Port a-Churraich; the Cobhan Cuillich, or Culdees' Cell, in a hollow between Dumii and Dumbuirg; the rath or hill-fort of Dumbuirg; and the Gleann-an-Teampull, or Glen of the Church, in the middle of the island. St. Oran's Chapel, now the oldest church in the island, may probably be of the later part of the 11th century. St. Mary's Nunnery is perhaps a century later. The Cathedral, or St. Mary's Church (c. 1203), whose min and precincts were made over by the late Duke of Argyll in September 1899, has a choir, with a north sacristy and south chapels; north and south transepts; a central tower, 70 feet high; and a nave. An inscription (defaced about 1849) on one of the columns of the choir seemed to denote that it was the work of an Irish ecclesiastic who died in 1203. On the north of the cathedral are the chapter-house and other remains of the conventual or monastic buildings. In the 'Reilig Oran'—so called, it is supposed, from St. Oran, a kinsman of St. Columba, the first who found a grave in it—were buried Egfrid, king of Northumbria, in 684; Godfred, king of the Isles, in 1188; and Haec Ospac, king of the Isles, in 1228. No monuments of these princes now remain. The oldest of the many tombstones on the island are two with Irish inscriptions, one of them, it is believed, being the monument of a bishop of Connor who died at Iona in 1174. To this interesting island a great Catholic pilgrimage took place in June 1888. For St. Martin's Cross, see Cross; see also the Duke of Argyll's *Iona* (1871; new ed. 1889), and other works cited at COLUMBA.

Ionia, the ancient name of the coast districts and islands of western Asia Minor. The name was derived from the Ionians, one of the four most ancient tribes in Greece. According to the usually received tradition, after being driven out of the Peloponnese, they removed to Attica, whence, about 1060 B.C., they sent forth warrior bands to settle on the bays and promontories and islands of Asia Minor; but it is more probable that the immigration was gradual and was spread over a long period of time. Although mountains, Ionia embraced the three valleys watered by the Hermus, Cayster, and Meander, and was a beautiful and fertile country, extending, according to Ptolemy, from the river Hermus to the river Meander, though Herodotus and Strabo make it somewhat larger. It soon reached a high point of prosperity; agriculture and commerce flourished; colonies were sent out, which settled on the shores of the Black Sea and in the south of Gaul (Masilias); and great cities arose, of which Ephesus, Smyrna, Clazomenae, Erythrae, Colophon, and Miletus were the most celebrated. These cities, with six others, formed the Ionian League. Each retained its independence, the form of government being democratical; but all met together periodically at Panionium, near Priene, for the discussion of such affairs and interests as they had in common, for religious worship, and for the celebration of athletic games. A few centuries later the twelve cities were made thirteen by the accession of Smyrna. These Ionian states were gradually subdued by the kings of Lydia. Then they passed (557 B.C.) under the sway of the Persians, but were allowed a considerable measure of internal liberty. They revolted, however, in 500, but were reduced to subjection after a bloody battle near Ephesus in 496 B.C. During the great Persian war the contingent which they furnished to their oriental

masters deserted to the Greeks at the battle of Mycale (479 B.C.); thereupon the Ionians entered into an alliance with Athens, upon which they now became dependent. By the peace of Antalcidas (387 B.C.) they were again made subject to the Persians, and remained so till the time of Alexander the Great. From this period Ionia shared the fate of the neighbouring countries, and in 64 B.C. was added to the Roman empire by Pompey, after the third Mithridatic war. In later times it was so ravaged by the Turks that few traces of its former greatness are now left.—The Ionians were regarded as somewhat effeminate. They were wealthy and luxurious; and the fine arts were cultivated amongst them at a much earlier date than amongst their kinsmen in the mother-country. Two of the celebrated temples of the Greek world, that of Diana and that of Apollo, both near Ephesus, were in Ionia. For Ionic architecture, see GREEK ARCHITECTURE. For the Ionian mode, see MUSIC. The Ionian School was the name given to the representative philosophers of the Ionian Greeks, such as Thales, Anaximander, Anaximenes, Heraclitus, Anaxagoras (see these names), who devoted themselves mainly to the question what was the primordial constitutive principle of the cosmical universe. The Ionic dialect, nearly akin to Attic, exceeds the other Greek dialects in softness and smoothness, chiefly from the greater richness of its vowel-system.

Ionian Islands, a group, or rather chain, of islands, about forty in number, stretching along the west and south coasts of Greece. Corfu (Corcyra), Paxo, Santa Maura, Ithaca (Theaki), Cephalonia, Zante, and Cerigo (Cythra) are the largest. Accounts of their physical features and other particulars will be found under the separate islands. Total area, 1010 sq. m.; pop. (1879) 244,133. (1889) 238,783, the great majority of Greek descent. The surface is generally mountainous, the plains and valleys being fertile. The collective term 'Ionian' is of modern date. Previous to the subjugation of Greece by Rome the only one of these islands that rose above the historic horizon was the Corinthian colony of Corcyra. On the division of the Roman empire these islands were included in the eastern half. In 1081 Corfu and Cephalonia fell into the hands of Robert Guiscard, and from that time they had a very chequered history for three hundred and twenty years. In 1491 Corfu came into the possession of the Venetians, who in the same century acquired Zante and Cephalonia, and subsequently most of the other islands included in the group. The Venetians retained them until 1797, when they ceded them to France. The islands were seized by Russia and Turkey in 1799; and the Emperor Paul created the Republic of the Seven United Islands, under the protection of Turkey. But in 1807 they were given back to France by the treaty of Tilsit. In 1809 Great Britain seized Zante, Cephalonia, and Cerigo, in 1810 Santa Maura, in 1814 Paxo, and after Napoleon's fall Corfu; and on November 5, 1815, were formed the United States of the Ionian Islands, under the protectorate of Great Britain. While they were connected with England the government was carried on by two assemblies and the Lord High Commissioner, the representative of the British government. The rule of the successive commissioners, although directed to the construction of roads, the regulation of the systems of taxation, the establishment of educational institutions, the reform of the administration of justice, and similar public works for the furtherance of the intellectual and material welfare of the people, was on the whole arbitrary and despotic. There was permanent friction, often of a severe character, between the representative of Britain and the representatives of the islanders.

Nor did the concessions of freedom of the press, an extension of the franchise, and freedom of election (with the right of the ballot), both municipal and parliamentary, extorted in 1849 by the disturbances of Europe during the year previous, do much to reduce the friction. Insurrections broke out amongst the peasantry; the discontent with British rule increased; and the party that agitated for incorporation with Greece waxed daily stronger. In the end of 1858 Mr Gladstone was sent as a special commissioner to ascertain what could be done to meet the claims of the population. He declared against annexation to Greece. But in 1863 the election of the son of the king of Denmark as constitutional king of Greece gave England an opportunity of getting rid of this troublesome dependency. On 14th November a treaty was concluded at London by which the islands were incorporated in Greece. In February 1867 they were visited by a series of earthquake shocks, most violent in Cephalonia, where they caused great destruction of life and property, and almost destroyed the two chief towns. The islands have now no geographical unity. Cythera (Cerigo) is included in the nomarchy of Argolis. The rest are distributed among the three nomarchies of Coreyra (Corin), Cephalonia, and Zacynthos (Zante). See works by Ansted (1863), Kirkwall (1864), Von Warsberg (Vienna, 1878-79), and Riemann (Paris, 1879).

Ions, the components into which an electrolyte is broken up on electrolysis. The one, the Anion (the electro-negative component—e.g. chlorine), travels 'against' the current (in its conventional direction in the circuit), and is deposited on or chemically attacks the anode or positive electrode; the other, the Cation (the electro-positive component—e.g. copper), travels 'with' the current to the cathode—e.g. to the spoons in the plating bath. See ELECTRICITY, Vol. IV. p. 270.

Iota. See I.

I O U, a memorandum of debt given by a borrower to a lender, so called from being made in this abbreviated form:

LONDON, 1st January 1880,

I O U Twenty Pounds.

To Mr C. D.

A. B.

It is a convenient document, because it requires no stamp, and yet it is valuable evidence of the existence of the debt, in case an action is afterwards brought. If, however, the I O U contain any promise to pay the debt, then it will amount to a promissory-note, and be void unless it have a stamp. It should be holograph, dated, and addressed to some person or persons, but it does not prove its own date.

Iowa, one of the United States of America, extends from 40° 36' to 43° 30' N. lat., and from 90° 15' to 96° 38' W. long., and has an area of 55,175 sq. m. It is bounded on the N. by Minnesota, on the E. by the Mississippi River, on the S. by the state of Missouri, and on the W. by the Missouri and Big Sioux rivers. The climate is continental, with cold winters, hot summers, and sudden changes of temperature. The autumns are beautiful and of long duration. The mean temperature of the year is 47°, and the annual rainfall about 33 inches. Iowa is noted for its healthfulness, the annual death rate being only 119 in every 10,000 of population. The surface is a rolling prairie; there are no mountains, and hills or bluffs can only be found along the principal streams. The average elevation is not far from 900 feet. The highest point (1694 feet) is about 70 miles E. of the north-west

corner of the state, and the lowest (444 feet) at the confluence of the Des Moines River with the Mississippi. The soil is unsurpassed in richness and productiveness, all the land being tillable except a few rocky bluffs near the large rivers. Natural forests cover the slopes that intervene between the rivers and the high lands, and since the cessation of the destructive prairie-fires the area of woodland has been steadily increasing. Iowa has also extensive and valuable mineral deposits, as coal, lead, gypsum, limestone, clay, and mineral paints. The coal, which is bituminous and of good quality, extends over an area of nearly 20,000 sq. m., and above 4 million tons have been raised annually of late years. The Mississippi on the eastern, and the Missouri on the western border are navigable. To both of these are tributary a number of inland rivers, those of the Mississippi system flowing in a south-easterly, and those of the Missouri system in a south-westerly direction. The Upper Iowa, Turkey, Maquoketa, Wapsipinicon, Iowa (with its large affluent the Cedar), Skunk, and Des Moines rivers are the principal tributaries of the Mississippi. The rivers of the Missouri system are the Big Sioux, Rock, Floyd's, Little Sioux, Boyer, and Nishnabotony. There are also several small lakes in the northern portion of the state, situated principally near the great water-sheds.

Iowa is pre-eminently an agricultural state. The nature of the surface offers excellent facilities for the use of agricultural machinery, and makes farming attractive and profitable. Nearly two-thirds of the 34 million acres of tillable land are now under cultivation, producing annually 300 million bushels of maize, 30 million bushels of wheat, 60 million bushels of oats, 4 million bushels of barley, 2½ million bushels of flax, 1½ million bushels of buck-wheat, half a million bushels of rye, 6 million tons of hay, 2 million gallons of sorghum-syrup, 10 million bushels of potatoes, 100 million pounds of butter, 5 million pounds of cheese, 2 million pounds of wool, and 32 million dozen eggs. The number of live-stock at the census of 1890 were as follows: horses, 1,312,079; cattle, 4,000,000; mules, 41,648; swine, 7,000,000; sheep, 450,000. The total annual value of all agricultural products may be fairly estimated at 300 million dollars. While Iowa has good water-power, cheap fuel, and excellent transportation facilities, the development of its manufacturing interests has been but slow. In 1880 the number of manufacturing establishments was 6921; the number of persons employed in them, 28,372; and the value of their annual products, \$71,045,926. In 1890 there were 7440 factories, with 59,174 workers, producing goods of the value that year of \$125,049,200. Among the leading articles of manufacture are flouring and grist-mill products, packed meats and canned goods, sawed lumber, carriages and wagons, saddlery, agricultural implements, furniture, bricks and tiles, foundry products, woollen goods, and clothing. The commerce is chiefly domestic. The principal exports are agricultural and dairy products, coal, gypsum, and lead; the imports, groceries and manufactured goods.

The legislative authority is vested in the general assembly, consisting of two houses, the senate (50 members) and house of representatives (100), and meeting in regular session in January of each even-numbered year. The supreme executive power is vested in a governor, who is elected for a term of two years. The supreme court consists of five judges, elected for a term of six years. The state is divided into ninety-nine counties, and is represented in the national congress by two senators and eleven representatives. The educational policy of the state is most liberal. Schools are established

in every district, and must be kept in operation at least six months each year. The school system embraces the district and high school, the state university, state normal school, and state agricultural and industrial college. In 1890 there were 26,769 teachers in about 17,000 common schools, which were attended by 503,755 pupils. Upwards of twenty high schools (including the state university, Drake University in Des Moines, and Cornell College) have nearly 400 teachers and over 7,000 pupils. Iowa has the lowest percentage of illiteracy of any state in the Union. Of 324,096 inhabitants born abroad, 127,246 were German born (1890). The value of property is estimated at 2,000 million dollars.

The territory of the state of Iowa formed part of the 'Louisiana Purchase.' After Iowa had successively been under the jurisdiction of the territorial governments of Missouri, Michigan, and Wisconsin, it was organized as a separate territory on the 4th of July 1838, with Burlington as its capital. It had then sixteen counties and a population of 22,860. The following year the general assembly located the seat of government at Iowa City. On 28th December 1846 the state was admitted into the Union, with a population of nearly 100,000. In 1856 Des Moines became the permanent capital. Iowa's population in 1850 was 192,214; in 1860, 674,913; in 1870, 1,194,020; in 1880, 1,624,615; and in 1890 it was 1,911,896; and Iowa was the tenth state in the Union in respect of population. In 1890 there was within the limits of the state one city (Des Moines) of over 50,000 inhabitants; five between 20,000 and 40,000 (Sioux City, Dubuque, Davenport, Burlington, Council Bluffs); five between 10,000 and 11,000; and twelve between 4,000 and 10,000.

Iowa City, capital of Johnson county, Iowa, and the seat of the territorial and state government from 1839 to 1836, is situated on the Iowa River, 120 miles by rail E. of Des Moines. The old capitol is now the home of the state university. The town has a foundry and a number of mills and factories. Pop. (1880) 7123; (1890) 7106.

Ipecacuanha, the name both of a very valuable medicine and of the plant producing it. The plant (*Cephaelis Ipecacuanha*) belongs to the natural order Cinchonaceae, and is a native of the damp shady woods in Brazil and some other parts

Ipecacuanha (Cephaelis Ipecacuanha) in flower:
a, the root.

of South America. More recently it has been cultivated in India and Ceylon, although there is a tendency under cultivation for the plant to run into varieties. It is somewhat shrubby, with a few oblong lanceolate leaves near the ends of the branches, long-stalked heads of small white flowers, and soft dark purple berries. The part of ipecacuanha used in medicine is the root, which is simple or divided into a few branches, flexuous, about

as thick as a goose-quill, and is composed of rings of various size, somewhat fleshy when fresh, and appearing as if closely strung on a central woody cord. Ipecacuanha root is prepared for the market by mere drying. It is collected at all seasons, although chiefly from January to March. The plant is never cultivated in Brazil. It has now become scarce in the neighbourhood of towns, but, owing to the readiness with which it is propagated from portions of the root, it is not likely to be exterminated.

It is in the bark of the root that the active principle, the *emetic*, almost entirely lies; the other ingredients, such as fatty matters, starch, lignine, &c., being almost inert. Emetine is represented by the formula $C_{28}H_{40}N_2O_{15}$. It is a white, inodorous, and bitter powder, moderately soluble in alcohol, and having all the characters of the vegetable alkaloids. It acts as a violent emetic in doses of $\frac{1}{16}$ th of a grain or less, and is a powerful poison. In good specimens of root it is present to the extent of nearly 1 per cent. In small and repeated doses—as, for instance, of a grain or less—ipecacuanha increases the activity of the secreting organs, especially of the bronchial mucous membrane, and of the skin. In larger doses of from 1 to 5 grains it excites nausea and depression; while in doses of from 15 to 30 grains it acts as an emetic, without producing such violent action or so much nausea and depression as tartar emetic. Ipecacuanha is useful as an emetic when it is necessary to unload the stomach in cases where there is great debility, or in childhood. As a nauseant, expectorant, and diaphoretic it is prescribed in affections of the respiratory organs, as catarrh, hooping-cough, asthma, &c.; in affections of the alimentary canal, as indigestion and dysentery; and in disorders in which it is desired to increase the action of the skin, as in diabetes and in febrile affections.

Besides the Powder, the most useful preparations are the Wine of Ipecacuanha—of which the dose to an adult as a diaphoretic and expectorant ranges from 10 to 40 minims, and as an emetic from 2 to 4 drachms—and the Compound Ipecacuanha Powder, commonly known as *Dover's Powder* (q.v.). To produce the full effect as a sudorific a dose of 10 grains of Dover's Powder should be followed by copious draughts of white-wine whey, treacle-posset, or some other warm and harmless drink.

Iphigenia, in Greek legend, a daughter of Agamemnon and Clytemnestra, or, according to others, an adopted daughter of Clytemnestra. Her father, having offended Artemis, could only avert the wrath of the goddess by promising to sacrifice to her the most beautiful thing born within the year. This happened to be Iphigenia. When Iphigenia was brought to the altar, however, she disappeared, and a hind lay there in her stead; Artemis herself carried her off in a cloud to Tauris (Crimea), where she became her priestess, but was afterwards recognised by her brother Orestes, who took her, along with the image of Artemis, to Attica. The legend is of post-Homeric origin, but evidently goes back to the barbaric stage of the Greek religion, when human sacrifices were wont to be made on solemn occasions. It gave a subject to painters, sculptors, and poets, and is imperishably enshrined in two splendid tragedies of Euripides. In modern art it has employed the genius of Gluck in music, and of Racine and Goethe in poetry.

Ipomoea, a genus of plants of the natural order Convolvulaceae, differing very little from the genus *Convolvulus* (q.v.).

Ipsambul. See *ARU SIMBEL*.

Ipsus. See *ANTIGONUS*.

Ipswich, the county town of Suffolk, 69 miles N.E. of London by rail, is situated on the side of a hill on the left bank of the river Gipping, which, here taking the name of the Orwell, becomes tidal, and after a south-easterly course of 12 miles more falls into the German Ocean at Harwich. In the older portions of the town, principally grouped near the river, the streets are narrow and irregularly built, and still retain many picturesque old buildings, decorated with carved work, such as Sparrowe's House (1567), the Neptune Inn (1639), Archdeacon's Place (1471), and Wolsey's Gateway (1528). Of public buildings the principal are a town-hall (1868), in the Italian Renaissance style of architecture, surmounted by a clock-tower 130 feet high; post-office (1881), and corn exchange (1882), both close by, and in the same style; public hall (1868); museum, schools of science and art, and free library (1881-87), the first of which, founded in 1847, is notable for its splendid collections of Suffolk Crag fossils and British birds; custom-house (1845); mechanics' institute (1824); hospital (1835-69-77); barracks; and a theatre (1891), on the boards of whose predecessor Garrick, Mrs Keeley, and Mr Toole made their debut. The churches are sixteen in number, mostly built of flint, and in the Perpendicular style, having as the principal or "metropolitan" church St Mary Le Tower, with a tower and spire 176 feet high, and a fine peal of twelve bells. Of educational establishments the principal is the grammar-school, dating from at least 1477, reorganised by Queen Elizabeth in 1565, moved into new buildings, of which the foundation-stone was laid by the Prince Consort, in 1851, and reconstituted under a new scheme in 1881; it has an income from endowment of £500, and eight scholarships of an aggregate annual value of £233. Near it are two arboretums, charmingly laid out, and Christchurch Park, with its fine Tudor mansion (1549). Another favourite resort is the promenade by the river-side, skirting the west side of the dock. This latter, opened in 1842, covers 30 acres, and is approached from the Orwell by an entrance lock (1881) capable of admitting vessels of 1400 tons. The principal manufactures are those of agricultural implements, railway plant, artificial manures, and clothing. In the history of Ipswich the chief events deserving mention are its pillaging in 991 and 1060 by the Danes; the granting in 1199 of its first charter by King John; the appointment of its first and only suffragan bishop (1525); visitations of the plague (1603 and 1666); partial destruction by fire (1654); and visits of Elizabeth (1561 and 1565), George II. (1736), and George IV., when Regent, Cardinal Wolsey, Dr William Butler (physician to James I.), Bishops Brownrigg and Lany, Clara Reeve, and Mrs Sarah Trimmer were natives, and Gainsborough the painter a resident for fifteen years. Ipswich has returned two members to parliament since 1447; and its population, in 1801 only 11,336, had risen in 1841 to 25,264, in 1881 to 50,546, and in 1891 to 57,360. See works by Clarke (1830), Woldenspoon (1842-50), Glyde (1850-87), and Dr J. E. Taylor (1889).

Ipswich, a town of Queensland, on the river Bremer, 23 miles W. of Brisbane by rail. It stands in a rich coal-mining district. Pop. with suburbs (1891) 10,190.

Iquique, the port and capital of the Chilean territory of Tarapacá (Peruvian till 1881). It has amalgamating works in connection with neighbouring silver mines, a foundry, and exports saltpetre, borax, and iodine. The climate is hot, and drinking-water has to be obtained by distillation. Earthquakes have more than once damaged the town. The roadstead is safe, and a mole has been built. Pop. (1876) 11,717; (1895) 33,931.

Iquitos, a town in the Peruvian department of Loreto, on the left bank of the Marañón, about 75 miles above the mouth of the Rio Napo. It has an active trade, valued at two million dollars annually; the imports are exchanged mostly for india-rubber. Pop. 8000—five-sixths Indians and half-castes.

Irak-Ajemi (Persian Irak), a central province of Persia, nearly coincident with ancient Media. A great portion of the surface consists of elevated tablelands, but there are also numerous fertile valleys only partly cultivated. The eastern parts are occupied by the extensive salt desert of Dasht-i-Kavir. The province contains the principal towns of the kingdom, including Teheran, the capital, and Isfahan. The industries are confined to the weaving of cloth and carpets, and the making of glass and porcelain. Area, 138,190 sq. m.; pop. estimated at a million.

Irak-Arabi (Arabian Irak), the most south-easterly district of Turkey in Asia, almost continuous with ancient Babylonia (q.v.), lies between the lower courses of the Tigris and the Euphrates, and includes the lands adjacent thereto. The region comprises the ruins of the ancient cities of Babylon, Seleucia, and Ctesiphon, and the modern towns of Bagdad, Basra, and Meshed Ali. The population is estimated to number nearly 2,000,000, chiefly nomads. Since 1867 cholera has been almost constantly prevalent.

Iran, or ERAN, originally the name applied to the great Asian plateau which has for its borders on the north the Hindu Kush and the Elburz, on the east the Indus, on the south the Persian Gulf, and on the west Kurdistan and the Tigris. The term is now the official designation of the kingdom of Persia. In early times the inhabitants of the Iranian plateau, together with the peoples of the adjoining parts of India, bore the common appellation of Aryans. See ARYAN RACE.

Irawadi, or IRRAWADDY, the principal river of Burma. Its sources are not known with certainty. A favourite origin for it with some authorities was the Sampo (q.v.), the great river of Tibet. But this has been shown in 1878-82 to be the upper waters of the Brahmaputra. In 25° 50' N. lat., a short distance above Bhamo, two arms, the Mali-kha and the Meh-kha, unite to form the river that is undoubtedly the Irawadi of Burma. Those two arms are believed to have their sources in the Namkin or Khanung range, that walls in the Zayul basin on the south; they certainly come from that direction. But General Walker, late of the Indian Trigonometrical Survey, is responsible for the hypothesis, advanced in 1887, that the right-hand or eastern branch, the Meh-kha, is the southward continuation of the Lu-Kiang, which has hitherto been regarded as the upper part of the Salwin; and he also identifies the Lu-Kiang with the Giama-nu-chu or Nu River, which rises in the north of Tibet and has a course, south-easterly, of some 700 miles in that country. From Bhamo the Irawadi has a very sinuous channel, its predominant direction being, however, south. Over this entire stretch (about 700 miles) it is navigable for small boats, in spite of numerous islands and sandbanks that litter and impede its channel, and in spite of two rock-bound defiles through which it passes between Bhamo and Mandalay. A third defile occurs nearly 100 miles above Bhamo. Its waters are muddy and its current generally rapid. Before reaching the sea, in nearly a dozen mouths, in the west of the Bay of Martaban, the river spreads out in a wide delta, 18,000 sq. m. in extent. Of its mouths two only are used by sea-going vessels, the Bassien on the west and the Rangoon on the east. The valley and plain of the Irawadi are very fertile, and grow vast quantities

of rice. The river is the chief artery of the country; on its banks stand the principal towns, Bassain, Rangoon, Prome, Ava, Mandalay, Blanno; its banks were the home of Burmese civilisation; its waters have served as the main means of communication not only to the interior of Burma, but to the south-western provinces of China and of Tibet. The river drains an area of at least 158,000 sq. m. Its largest affluent, coming from the right hand, is the Chindwin. This and the two left-hand tributaries, the Shweli and Myitnge, are alone navigable. The plain for 150 miles from the sea, being liable to annual inundations, has been protected by embankments built along each side of the river since 1863. The carriage of goods and merchandise is shared between the steamers of the English 'Hawala Flotilla Company' and a numerous fleet of native boats. For the question of origin, see General Walker's papers in *Proc. Roy. Geog. Soc.* (1887 and 1888).

Irbit, a town of the Russian government of Perm, 1170 miles nearly due E. of St Petersburg. Its celebrated fair, held in February, is, next to that of Nijni Novgorod, the most important in the empire. Pop. 4242.

Ireland, an island forming part of the United Kingdom of Great Britain and Ireland, lies between 51° 26' and 55° 21' N. lat., and 5° 20' and 10° 26' W. long. It is washed on the N., W., and S. by the Atlantic, and on the E. by the North Channel (13 miles wide), the Irish Sea (138 miles), and St George's Channel (47 to 69 miles), which separate it from the larger island of Great Britain. It is an irregular rhomboid in shape, its greatest length, from Fair Head in Antrim to Crow Head in Kerry, being 302 miles; its greatest meridional length is 225 miles, and the average breadth 110 miles. The island was known to the Greek geographers as *Ierna* (Strabo), and to the Latins as *Hibernia* and *Juverna*. From the latest of the prehistoric occupants of 'The Green Island,' the invading Milesians or Scots, came the Latinised *Scotia*, one of the names by which the 'Isle of Saints' was known from the 6th till the 13th century.

Area.—Ireland is divided into the four provinces of Ulster, Leinster, Munster, and Connaught, which again are subdivided into thirty-two counties. The total area is 20,819,928 acres, or 32,531 sq. m., or nearly two thirds of that of England without Wales. Of the total area 15,066,761 acres were in 1889 arable and grass land, 326,343 acres were covered with wood, and 1,935,649 acres were bog, waste, roads, &c.

Population.—In 1801 the population of Ireland was 5,395,156 (a density of 166 per sq. mile); in 1841 this had increased to 8,175,124 (251 per sq. mile); thereafter set in, owing to emigration, a steady decrease, so that in 1891 the population was only 4,704,750 (144 per sq. mile). In 1891, 936,759 belonged to the agricultural class, 656,410 to the industrial, 255,114 to the domestic, 214,343 to the professional, and 83,173 to the commercial. In 1881 Ireland had only six towns with populations exceeding 20,000, and in 1891, eight; of which Dublin had 361,891, and Belfast 255,950. In 1890, 57,484 persons, and in 1891, 58,436 persons emigrated from Ireland, the vast majority of them going to the United States. By far the greatest number who left Ireland in one year emigrated in 1883—108,724. According to Mr Parnell, in 1890 there were in England and Scotland 750,000 persons of Irish birth (with probably 1,500,000 descendants). At the census of 1890 there were in the United States 1,854,971 persons of Irish birth; between the years 1821 and 1889, 3,413,152 Irish persons settled in the States. In 1881 there were in Canada

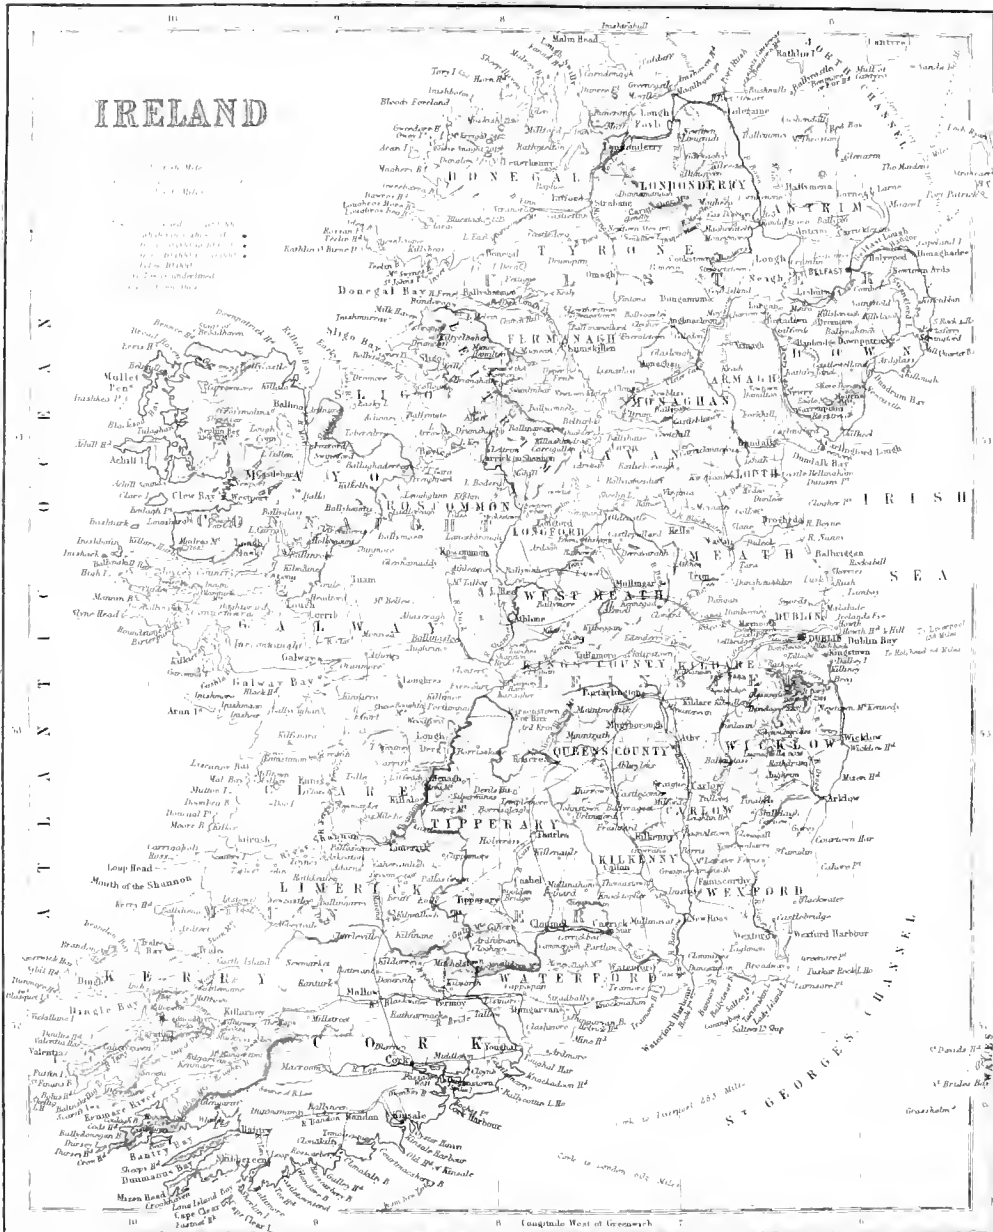

957,403 persons 'of Irish origin' (more than those of English origin, nearly twice as many as those of Scottish origin). In Victoria there were in 1881, 86,750 Irish; in Queensland, 21,300; in Western Australia, about 3000; in New Zealand, 50,000. In the other Australian colonies, South Africa, &c., the census does not distinguish precisely between the various British elements of population. During the thirty-seven years 1853-89, 2,775,007 Irish emigrated; 2,289,735 to the United States, 173,343 to Canada, and 289,733 to Australia. In 1851-99 the total was 3,796,131.

* The figures for 1881 and 1891 include the soldiers and sailors serving in Ireland; the figures for 1841 exclude them.

Coasts and Physical Aspects. The eastern coast is comparatively uniform and even; but the coasts on the north, west, and south are in many places rocky and high, and indented with numerous deep bays, especially at the south-west corner of the island. Most of these bays afford excellent harbours, some even for the largest of modern warships. On the west may be named the Bays of Donegal, Sligo, Clew, Galway, the estuary of the Shannon, and Dingle, Kenmare, and Bantry bays; on the south the spacious harbours of Cork and Waterford; on the north Loughs Foyle and Swilly, which both penetrate a long distance inland. On the east side, opposite England, are Wexford Haven, the Bays of Dublin, Drogheda, and Dundalk, and Carlingford and Belfast loughs. Numerous islands occur, especially on the west, but they are for the most part small in size. Valentia, in the extreme south-west, was the terminus on the British side of the first Atlantic cables to North America, as those of 1858, 1865, and 1866, and of others since

IRELAND

then. On the west too are the islands of Aran, Achill, the Inishkeas, &c. Off County Antrim, in the north-east, are Rathlin Island and the Giants' Causeway (q.v.). Dangerous points on the coasts, and some low groups of rocks, are protected by fifty-seven lighthouses and three floating lights.

The surface is, generally speaking, an undulating plain, relieved, more particularly towards the coasts, by detached groups of low hills. The principal ranges are the Mourne Mountains in Down, which attain their highest elevation in Slieve-Donard (2796 feet); the mountains of Wicklow, which rise in Lugnaquilla to a maximum height of 3039 feet; and Macgillivuddy's Reeks, in Kerry, their highest peak, Carran-Tuail (3414 feet), being the loftiest in all Ireland. The central parts of the island are quite flat, and consist very largely of bogs or morasses, which occupy altogether 1,772,450 acres, or nearly one-ninth of the entire area. The largest is the Bog of Allen, which stretches over a large portion of Kildare, Carlow, King's, and Queen's counties. These bogs have an average depth of 16 to 25 feet, but occasionally go down to 47 feet; they yield large quantities of peat or turf, and contain numerous remains of skeletons of men and animals, and relics of human habitation and occupancy. Extensive tracts of deep wet bog occur in Longford, Roscommon, and other counties, and give a peculiarly dreary and desolate aspect to the scenery. Notwithstanding the quantity of water in these bogs, they exhale no miasma injurious to health, owing to the large quantity of tannin which they contain.

Hydrography.—The principal river of Ireland, and the largest in the United Kingdom, is the Shannon (q.v.). The streams which drain the eastern part of the central plain are the Liffey and Boyne; the south-eastern part, the Suir, Barrow, and Nore; while the waters of the north-eastern part are collected into Lough Neagh, chiefly by the Blackwater, and are thence discharged into the sea by the Lower Bann and Newry Canal. The rivers external to the great central plain are necessarily short. The principal are the Erne, flowing to the north-west; the Foyle and Bann, to the north; the Lagan, to the north-east; the Slaney, to the south-east; and the Bandon, Lee, and Blackwater, to the east, through the county of Cork. None of these rivers are of much importance to navigation beyond their estuaries, though small boats can ascend some distance up the larger streams by the aid of canals, locks, &c. Artificial rivers or canals connect some of the more important trading centres; for instance, Dublin has water-communication with the Shannon by means of the Grand (165 miles) and Royal (76) canals, and Lough Neagh with the same river by the Ulster Canal and river Blackwater.

The lakes of Ireland (called loughs) are both numerous and extensive in proportion to the size of the island. The largest is Lough Neagh in Ulster, covering an area of nearly 100,000 acres. The other loughs of consequence are Erne and Derg, also in Ulster; Conn, Mask, and Corrib, in Connaught; Allen, Ree, and Derg, expansions of the river Shannon; and the lakes of Killarney (q.v.) in Munster. The name lough is also applied to many salt-water inlets (see above).

Geology. The configuration or relief of Ireland is, as a matter of course, intimately related to the geological structure of the island. The mountains are built up of relatively hard crystalline schists and disturbed Lower Palaeozoic rocks, while the low grounds are nearly co-extensive with less indurated and comparatively undisturbed Upper Palaeozoic strata. The interior and larger portion of the

island is in fact a great undulating plain, the central area of which, between Dundalk Bay or Dublin Bay in the east and Galway Bay in the west, does not exceed a height of 250 feet above the level of the sea. The strata throughout this central plain belong almost exclusively to the Carboniferous system. Here and there the ground rises to heights ranging between 1000 and 3000 feet so as to form more or less isolated hills and groups of hills and mountains as Slieve Bloom, the Silvermine Mountains, Slieve Bernagh, Galtymore, &c. These are simply islets of older Palaeozoic rocks that peer above the general level of the great Carboniferous plain. The chief highlands of the island are met with in the maritime regions. Thus we have in the north the highlands of Donegal and Derry, the plateau-basalts of Antrim, and the Mourne and Carlingford Mountains with Slieve Gallion; in the south the highlands of Kerry and Cork, with Knockmealdown, &c.; in the west those of Mayo, Galway, and Connemara; and in the east the mountains of Wicklow.

Ireland is thus built up chiefly of Palaeozoic rocks—strata of Mesozoic and Cainozoic age being very meagrely developed. *Archaean* gneissose and schistose rocks occur chiefly in the north-west and west—the coarse granitic gneiss of Donegal being regarded as belonging to the same series as the gneissose rocks of the north-west Highlands of Scotland. The oldest of the fossiliferous systems, the *Cambrian*, is well represented in the south-east of Ireland, where it attains a thickness of 14,000 feet at least. The strata are upon the whole unfossiliferous, but numerous surface-markings have been detected, chiefly worm-tracks, &c. In many places these rocks have been much metamorphosed. Thus on the Howth coast they are represented by quartz-rocks and schists, while in Wexford they pass into gneiss. Similarly in Galway over considerable tracts the Cambrian seems to be represented by schistose rocks; some of these, however, seem to be of Archaean age. The *Silurian* system is likewise well developed in the island—both lower and upper divisions being present. This system, like the Cambrian, occurs chiefly in the hillier parts of the country. In the Donegal district the rocks are much metamorphosed, and are doubtless the equivalents of the altered Lower Silurian strata of the Scottish Highlands. The same rocks reappear in Mayo and Galway; in the last-named district they are overlaid unconformably by unaltered Upper Silurian sandstones, conglomerates, and shales. Fossils occur here and there in the less altered portions of the Lower Silurian, but are not nearly so common as in the overlying upper division. It is noteworthy that not only are the Upper Silurian strata unaltered, but they contain rolled fragments of the metamorphosed Lower Silurian rocks upon which they rest. It may be added that contemporaneous volcanic rocks are associated with the Upper Silurian strata of Galway. Coming farther south we encounter another thick series of Upper Silurian strata in the Dingle promontory. In the districts of Waterford, Wexford, Wicklow, and Louth Lower Silurian strata are likewise well developed, and are noted for the evidence which they have supplied of contemporaneous volcanic action.

No representatives of the marine *Devonian* are known in Ireland, but the lacustrine or *Old Red Sandstone* type is well developed in the south and south-west. Two divisions are recognised—the upper unconformable to the lower, which latter reaches a great thickness. The rocks of the latter are chiefly grits and slates, which have yielded certain bivalve shells (*Anodonta*), probably of fresh-water origin, but no traces of the marine Devonian fauna. The upper division consists chiefly of flag-

stones and tilestones, and is of no great thickness. The chief fossils are worm tracks and ferns. This division appears sparsely in the centre and north of Ireland, where the general character of the strata recalls that of the Old Red Sandstone of central Scotland. The series passes up conformably into the Carboniferous system.

The *Carboniferous* system occupies about one-half of the area of Ireland, but the strata belong chiefly to the lower division—viz. the Lower Carboniferous and the Carboniferous limestone, which latter is essentially the formation of the plains. The upper members of the system occur in a few detached patches scattered over the surface of the great central plain, the major portion of which was probably at one time covered with Upper Carboniferous strata. The basement beds of the system in the south of the island consist chiefly of marine grits and slates, which pass down conformably into the Upper Old Red Sandstone. In the centre and north this lower division is represented by conglomerates, grits, sandstones, shales, and earthy limestones, which appear to be the equivalents of the 'Calcareous sandstones' of Scotland. Overlying these basement beds comes the great Carboniferous limestone (2500 to 5000 feet thick), which occupies most of the central plain, extending east and west from sea to sea, and stretching from the base of the Donegal Mountains to the foot of the Killarney Mountains in the south. In Donegal the limestone rises into a tableland which overlooks the shores of Donegal Bay in bold bluffs and headlands, and reaches from 1500 to 2000 feet above the level of the sea. Contemporaneous volcanic rocks accompany the limestone series in the south-west (Limerick and Tipperary). In the south and in the north the limestones are overlaid by marine sedimentary deposits which are believed to be on the same general geological horizon as the 'Yoredale beds' and 'Millstone grit' of England. Succeeding this group comes the 'Coal measures' series, the lower portion of which is supposed to represent the 'Gannister beds' or lower coal-measures of England, while the upper portion represents the middle coal-measures of the same country. The productive coalfields of Ireland are of small extent. They are confined to limited districts in the north and south, as in Tyrone, Tipperary, Kilkenny, and Carlow—all the coal of the south of Ireland being anthracitic.

The Upper Paleozoic and Cainozoic rocks of Ireland are confined to the north east of the island, where they appear to owe their preservation in chief measure to the great outflows of basalt which form the high grounds of Antrim. *Permian* strata are very sparingly developed, but both the Lower Permian and the overlying Magnesian limestone of England are represented. The lower division is characterised by the presence of coarse breccias like those of Shropshire. The Permian is seen at Armagh and in Tyrone.

The *Triassic* system is likewise sparingly represented, occurring in a narrow band round the basalts of Antrim and Derry. The rocks are chiefly red and mottled sandstones and marls, with gypsum and extensive beds of rock salt. These strata are overlaid by certain dark shales, which have yielded 'Rhaetic' fossils.

The great *Jurassic* system of England is for the most part unrepresented in Ireland, but a few shales which come out from underneath the chalk escarpment of Antrim have been identified by their fossils as pertaining to the Lower Liás.

Cretaceous strata (Upper Greensand and Chalk) crop out from underneath the basalts of Antrim, to which doubtless they owe their preservation. There is reason to believe that the Cretaceous beds formerly covered a much more extensive area in

the north of Ireland. They may at one time have extended continuously from the high grounds of Donegal in the north-west to the Mourne Mountains in the south-east.

The Tertiary or Cainozoic rocks consist chiefly of volcanic accumulations (trachytes and basalts); their age is determined by the occurrence of intercalated 'leaf-beds,' the plants in which show that the series belongs to the *Oligocene* system. Many of the basalts are beautifully columnar (Giants' Causeway). The volcanic rocks appear to have been the products of great fissure-eruptions for the most part, but the 'necks' or plugged-up throats of isolated volcanic foci have been detected. The whole area in this north-east part of Ireland is traversed in all directions by basalt dykes.

Along the southern shores of Lough Neagh fresh-water clays occur, the fossils in which are of *Pliocene* age, so that this Irish lake is probably the oldest sheet of fresh water in the British Islands.

Ireland, like the sister island, abounds with evidence of the *Glacial* period. The whole country has been buried under a great *mer de glace*, which was continuous with that of Scotland and England. The bottom-moraines (boulder clay) of this ice-sheet are encountered everywhere. Irish geologists recognise two boulder-clays separated by intervening stratified deposits of marine origin (see *PLEISTOCENE SYSTEM*). Local moraines due to the 'retreat' of the great *mer de glace* are common in mountain valleys. *Recent deposits* are seen in raised beaches, alluvial terraces, and bogs.

Ireland's mineral produce is small. In 1896, 129,585 tons of coal were raised; the iron ore is less in value. Salt is made; pyrites, barytes, and lead ore are produced, as well as stone, marble, sand, clay for making aluminium, &c.

Animals.—Twenty-one species found in Great Britain are unrepresented in Ireland. Frogs are common enough, also toads; but the mole, adder, shrew, water-shrew, water-vole, the two land-voles, wild-cat, polecat, weasel, and roe-deer are unknown; only the blue hare is indigenous.

Climate.—The climate resembles that of Britain, but is modified by Ireland's different surface, its greater distance from the Continent, and the more direct influence of the Gulf Stream. The mean annual temperature for the thirty-four years ending with 1889 was 50.0; the annual mean temperature of England is 49.5, that of Scotland 47.5. In Ireland there are 3 of difference between the extreme north and south. In January the mean temperature at inland situations in the north is 39.5, whilst in the extreme south-west it is 45.2; whilst in July the extreme mean temperatures are 58.2 at Malin Head in the north and 60.5 at Parsonstown in the interior. Thus in winter the difference of temperature of different districts is 5.7; but in summer it only amounts to 2.3. Ireland enjoys, therefore, a climate more equable in all seasons than those parts of Great Britain which are within the same latitudes. The mean annual rainfall for the twenty-four years ending 1883 varied from 28.48 inches at Dublin to 89.40 inches at Kylesmore, in Galway. These amounts, which are the extremes, are, however, restricted to very limited areas. About half the whole island has a rainfall of from 30 to 40 inches, and the other half from 40 to 50 inches, the former region being in the east and the latter in the west. Thus the rainfall is very much more equally distributed over Ireland than over Great Britain. The rainfall in winter is greatly in excess of that in the other seasons, particularly in the west, owing to the low temperature of the surface of the ground, which chills the warm and moist south-west winds that prevail at this time of the year. In Great Britain the chief

mountain-ranges are in the west, and lie from north to south; consequently over the whole eastern slope of the island the climate is drier, the amount and frequency of the rainfall much less, and the sunshine more brilliant than in the west. In Ireland, on the other hand, the hills in the west do not oppose such a continuous barrier to the onward progress of the south-west winds, but are more broken up and distributed in isolated groups. Consequently the sky is more clouded, and rain falls more frequently and more generally over the whole of Ireland than Great Britain, and the climate is thus rendered more genial and fostering to vegetation; hence the appropriateness of the name 'Emerald Isle.' Again, owing to its greater distance from the Continent, the east winds of spring are less severely felt in Ireland, because they have acquired warmth and moisture in their progress westward over Great Britain and the Irish Sea. Queenstown, in the south-west of Ireland, enjoys an average spring temperature of 49°, which is about 25° higher than at Dover on the coast of Kent.

Agriculture.—Down to about the middle of the 18th century Ireland was almost exclusively a pastoral country. Yet the soil is in many parts eminently adapted to tillage. The chief reasons of the backwardness of agriculture have been prohibitive and un-suitable legislation, the extreme smallness of the greater number of holdings, the lack of capital, and the unsatisfactory relations of landlord and tenant. As a rule large farms were let for extremely long periods of tenancy, and the tenants sublet their farms in smaller portions, sometimes two or three times over; consequently the landlords seldom erected buildings, repaired farmsteads, or made permanent improvements. In 1879-80 the distress amongst the poorer sections of the community had reached such a pitch that the government took action, and in 1881 the Land Law (Ireland) Act was passed. Its principal measures were designed to protect the tenant from paying more than a 'fair rent,' and to provide for loans being made to tenants to enable them to purchase their holdings on fair and equitable terms. To illustrate the smallness of the holdings in 1841: there were in that year 310,436 holdings above 1 acre and less than 5 acres; 252,799 from 5 to 15 acres; but only 79,342 from 15 to 30 acres, and only 48,625 above 30 acres each. The subjoined table will show the rate at which the small holdings have decreased in number and the larger holdings have increased:

Year.	1 to 5 acres.	5 to 15 acres.	15 to 30 acres.	Above 30 acres.
1871	74,809	171,383	138,447	159,303
1881	67,071	164,945	135,793	169,834
1888	61,816	154,441	133,749	174,245

Of the holdings above 30 acres in extent in 1888, 73,763 ranged between 30 and 50 acres, 56,476 between 50 and 100 acres, 22,796 between 100 and 200 acres, 8,372 between 200 and 500 acres, and only 1561 exceeded 500 acres in extent. In the same year there were 47,951 holdings each less than one acre. Contemporaneously with these changes there has been a steady but very noticeable return to a predominance of pasture, as will be apparent from the variation of acreage shown in the following table:

Year.	Cereal Crops.	Green Crops.	Meadow and Clover.	Flax.
1869	2,208,548	1,460,294	1,670,716	229,252
1879	1,761,867	1,294,600	1,975,255	128,021
1889	1,534,922	1,219,549	2,189,085	113,817

Oats, barley, and wheat, in the order named, are the chief cereals grown. Under green crops are included potatoes, turnips, cabbage, carrots, vetches, and similar crops. The extent of land set apart for potatoes, the staple food of the peasantry, has also decreased very largely: in 1869 potatoes

occupied 1,041,902 acres; in 1879, 842,671; and in 1889, 787,152 acres. About 10 million acres are permanently under grass, and about 330,000 acres are covered with woods. During the last fifty years a relatively large area has been reclaimed and converted into cultivable soil; in 1841 the waste land, including bogs, amounted to 6,489,971 acres; in 1889 the same category included 4,935,649 acres. The next table shows the fluctuations in the number of live-stock at intervals of ten years:

Year.	Horses, Mules, and Asses.	Cattle.	Sheep.	Pigs.
1869	719,421	3,733,675	4,651,195	1,082,224
1879	785,025	4,967,094	4,017,880	1,071,990
1889	910,942	4,933,394	3,789,620	1,389,548

In 1895 there were 1,439,053 acres in corn crops, 1,151,582 in green crops, and 95,202 in flax.

Fisheries.—The seas around the coasts of Ireland teem with fish; but from various causes, chiefly perhaps the distance of the most productive fishing-grounds from the centres of population, the fisheries are not in a flourishing condition. Large quantities of cured fish (3648 tons in 1887) are even imported from Scotland. In 1890-95 the Irish fisheries were prosecuted by 27,000 men and boys in 6000 boats, whereas forty years before 100,000 men and boys were engaged in this calling on 20,000 boats. The deep-sea fish of greatest commercial value are mackerel, herrings, hake, soles, cod, lobsters, and oysters. In 1887 herrings were exported to England to the value of £152,168, mackerel to the value of £88,775, and cod to £142,734. The most prosperous fishing is that for salmon, in which about 13,000 men are employed. The total value of salmon exported in some years amounts to as much as £500,000. The total value of Irish fisheries in 1895 was £269,000, not including salmon.

Manufactures.—Ireland is not and never has been a manufacturing country. Its unsettled state and the general dependence of the population on agriculture have hitherto been obstacles to the formation of great manufacturing establishments, except in the north-east, in Ulster. The staple industry is the manufacture of linen, introduced into Ireland by Strafford in 1633, and much encouraged by the Duke of Ormonde (1661-64). In 1881 the number of spindles employed in this manufacture was 927,300, and of power-looms 21,200; in 1887 the figures were respectively 803,026 and 24,300. The chief seats of the industry are Belfast and other towns in Ulster. In 1889 nearly 1056 flax-scutching mills were employed. The manufacture of woollen, silk, and cotton stuffs and of paper is also carried on, but only to a comparatively inconsiderable extent. In the 17th century the woollen manufactures of Ireland were in a most flourishing condition, producing principally frieze and flannel. But vexatious measures, prohibitive and restrictive, by the English parliament almost destroyed the industry before the century came to an end. Instead of 30,000 persons employed in this industry in 1641, there were only 7710 (in less than fifty factories) in 1881. The silk manufactures, since their introduction by French emigrants in the beginning of the 18th century, have been almost entirely confined to Dublin; poplin is still extensively manufactured there and in a few other towns. In 1890 there were 263 textile factories in Ireland, and nearly 30 distilleries.

Commerce and Shipping. The exportation of agricultural produce constitutes the bulk of the commerce, and by far the greater part of this trade (in cattle, sheep, pigs, salted meat, grain, flour, butter, eggs, and linen) is carried on with Great Britain, chiefly between Dublin and Belfast on the one side and Liverpool, Glasgow, and Bristol on the other. This trade has been assimilated with the coasting trade of the United Kingdom since

1825; consequently no separate statistics of it are kept, except for live animals and fish. Of these, 662,409 cattle, 606,391 sheep, 468,049 pigs, and 31,613 horses were exported to Great Britain in 1889. The foreign and colonial imports, consisting principally of grain, wine and spirits, fruits, petroleum, and timber, were valued at £7,232,669 for the year 1888, and the exports (chiefly linen and spirits) at only £870,873. The number of sailing and steam vessels engaged in the foreign and colonial trade that entered at Irish ports in 1880 was 1737 (tonnage, 960,820), and cleared 1086 (585,052 tons); the number engaged in trade with Great Britain that entered in the same year was 54,742 (12,145,116 tons) and cleared 52,803 (11,588,074 tons). Of vessels engaged in the trade with foreign countries and the colonies in 1888 there entered 1168 (731,285 tons), but cleared only 158 (67,418 tons). In the year 1894-95 the Irish imports were set down at £8,862,000, whereas the *direct* Irish exports were only £332,000.

Government, Police, &c.—The government of Ireland has since the union of 1801 been amalgamated with that of Great Britain. It is represented in the imperial parliament by 28 peers elected for life in the House of Lords and 103 members in the House of Commons. The executive is vested in a lord-lieutenant, who is assisted by a chief-secretary and a privy-council (appointed by the crown). The law is administered by a Lord Chancellor, a master of the Rolls, and the other judges of the Supreme Court of Judicature, which has two divisions—the High Court of Justice, with four divisions, and the Court of Appeal. Besides these, there are three commissioners or judges who preside over the proceedings of the Irish Land Commission, formed in 1881 for the purpose of adjusting 'fair rents' and other disputed matters between landlords and tenants. The Landed Estates Court (established in 1849) has since 1878 formed a branch of the Chancery Division of the High Court of Justice. For the county administration, see COUNTY. The Poor-law and Sanitary administrations devolved in 1872 upon the Local Government Board for Ireland. In 1887 a total of 521,832 persons were in receipt of poor relief, 134,757 getting outdoor relief, and the remaining 387,075 receiving relief in the 161 work-houses. This relief cost £857,820. In 1883 the expenditure reached its maximum, £1,042,845. Order and peace are maintained by the Royal Irish Constabulary, a body of armed police, numbering about 13,500 men, and the Dublin Metropolitan Police, a force of 1226 men. The Crimes Act, repeatedly re-enacted for the prevention of agrarian outrage especially, may at any time be put in force by the proclamation of any district. The Local Government Act of 1898 assimilated the administration of Ireland to that of Great Britain; and a new government department of agriculture, other industries, and technical education was established in 1899.

Religion.—By far the larger portion of the inhabitants of Ireland are Roman Catholics—3,960,891 at the census of 1881, and 3,547,307 in 1891. The Roman Catholic Church of Ireland is governed by four archbishops (Armagh, Dublin, Cashel, and Tuam) and 24 bishops. Irish Protestants numbered 1,159,147 in 1881, and 1,327,535 in 1891. Until January 1871 the established church of Ireland was the Episcopal Church, a branch of the Church of England. Since its disestablishment it is still known as the Church of Ireland, and is presided over by two archbishops (Dublin and Armagh) and eleven bishops. Its members numbered 639,574 in 1881, and 600,103 in 1891. In 1891 the Presbyterians reckoned 444,974 adherents, and the Methodists 55,509; while the Presbyterians had been

470,734 in 1881, and the Methodists, 48,839 in the same year. The relative numbers of Roman Catholics and Protestants of all creeds are shown for the several provinces in the subjoined tabular statement for the year 1881:

	Roman Catholic.	Protestant
Leinster	1,094,825	183,657
Munster	1,249,584	81,653
Ulster	833,593	909,106
Connacht	758,116	38,527

Education.—The primary schools of Ireland are mostly under the management of the Commissioners of National Education. These schools have since 1831 been open to Christians of every denomination, without compulsory attendance at any class of religious instruction, with in fact perfect freedom in all matters appertaining to religion. In 1881 there were 7648 of these schools attended by 1,066,259 pupils; in 1888 the numbers were 8196 schools and 1,060,895 pupils (826,181 Roman Catholics, 109,687 Church of Ireland, and 111,072 Presbyterians). They are partly under Protestant, partly under Roman Catholic teachers, and partly under teachers of both creeds in the same school, and are to a large extent supported by a parliamentary grant (£874,051 in 1887). In 1878 one million sterling, from the former endowment of the Irish established church, was set apart for the encouragement of secular intermediate education. The fund is administered by a board of nine commissioners, who conduct examinations, pay fees according to results, and present exhibitions, prizes, and certificates to successful pupils. In 1887 out of 3931 pupils who presented themselves for examination 3595 passed. The most important university in Ireland is that of Dublin (q.v.) or Trinity College. The Royal University of Ireland is not a teaching, but only an examining body, like the university of London. It was founded in 1880, and superseded the Queen's University; and it grants degrees irrespective of religious confession. The three Queen's Colleges of Belfast, Cork, and Galway, opened in 1849, and formerly affiliated to the Queen's University, provide instruction in the higher branches of learning. They were attended in 1887-88 by a total of 775 students. The Royal College of Science, established in 1867 in Dublin, was founded for the purpose of giving instruction in branches of science applicable to the industrial arts, especially in mining, agriculture, manufactures, and engineering. The Roman Catholic University of Ireland, founded in 1854, has its headquarters in Dublin; it is supported almost entirely by private contributions. St. Patrick's College, Maynooth (q.v.), opened in 1795, is the principal institution for the education and training of Roman Catholic priests. Until 1871 it received an annual parliamentary grant; but in that year this was compounded for by the payment of the sum of £372,331, in lieu of the grants. Two Presbyterian colleges, the General Assembly's Theological College, Belfast, and Magee College, Londonderry, were in 1881 empowered to grant theological degrees to their students. In 1887 there were in Ireland 69 industrial schools for boys and girls, 58, with 6496 pupils, being Roman Catholic, and 11, with 814 pupils, Protestant. In the same year 9 reformatory schools had 891 inmates. In 1888, 21.4 per cent. of the men and 23.2 per cent. of the women who were married signed the register by their mark.

Finance, Taxation. The net amount of revenue raised in Ireland for contribution to the imperial exchequer for the year ending 31st March 1895 was £5,981,896, of which £5,192,722 was derived from excise. In 1896 a parliamentary committee reported that, taking everything into consideration, Ireland was paying much more than her share of

imperial taxation. The national debt of Ireland (about 150 millions) was consolidated with that of Great Britain in 1817, and since that date the former has had no separate debt. The grand-jury cess, a tax peculiar to Ireland, corresponds to the highway rate of England and Wales, and is expended on roads, bridges, quays, prisons, courts of justice, police, public charities, county officers, &c. In 1887 the sum of £2,062,808 was owned by 49,994 depositors in the trustee savings-banks of Ireland, and the sum of £2,802,000 by 158,848 depositors in the post-office savings-banks. In 1894 the capital amount in the latter banks was £4,975,680, and in the former £1,997,495.

Communication.—The first railway opened in Ireland was the short line, of 6 miles long, between Dublin and Kingston, in 1834. In 1895 the number of miles open and in operation was 3044, an increase of 600 miles since 1881. The companies having the longest mileage are the Great Southern and Western, the Great Northern, the Midland Great Western, the Waterford and Limerick, the Belfast and Northern Counties, and the Dublin, Wicklow, and Wexford. The railways are constructed on a broader gauge than those of Great Britain—viz. 5 feet 3 inches, as compared with 4 feet 8½ inches; but several built since 1878 (see RAILWAYS) are only of 3 feet gauge. The local authorities have sanctioned the construction of 600 miles of tramways. The first considerable electric tramway in the United Kingdom was that from Portrush to the Giant's Causeway (1883). The canals, rivers, and lakes have been already mentioned. In the year 1894-95 the postal authorities in Ireland despatched 113 millions of letters and 65 millions of post-cards, newspapers, and parcels, and 4,038,262 telegrams, and issued 536,714 money orders (exclusive of postal orders) representing the sum of £1,364,000.

BIBLIOGRAPHY.—The earliest account of Ireland is contained in Giraldus Cambrensis, *Topographia Hibernia* and *Erpugnatio Hibernia*. Subsequent accounts will be found in Holinshed, *Chronicles* (1577); R. Payne, *Brief Description of Ireland* (1590); E. Hogan, *Descr. of Ireland in 1598* (1878); Sir J. Davies, *Discovery of the State of Ireland* (1613); Edmund Spenser, *Vicr of the State of Ireland* (1633); Sir Wm. Petty, *Political Anatomy of Ireland* (1691) and *Geog. HISTORY.—The history of Ireland, like that of almost all ancient countries, tracks its parent lake back into the enchanted realms of legend and romance and fable. It has been said, not untruly, of Ireland that she 'can boast of ancient legends rivalling in beauty and dignity the tales of Attica and Argolis; she has an early history whose web of blended myth and reality is as richly coloured as the record of the rulers of Alba Longa and the story of the Seven Kings.' We cannot

now make any effort to get at history in the beautiful myths and stories. We should puzzle our brains in vain to find out whether the Lady Cesair who came to Ireland before the deluge with fifty women and three men has any warrant, even the slenderest, from genuine tradition or is a child of fable altogether. We cannot get at any hint of the actual truth about Conn of the Hundred Fights and Fin Mac Coul and Oisín. But the impression which does seem to be conveyed clearly enough from all these romances and fables and ballads is that there was in Ireland a very ancient civilisation, and that the island was occupied in dim far-off ages by successive invaders who came from the south. The Phœnicians are said to have represented one wave of invasion and the Greeks another. Many an observer who had little in him of the merely fanciful has left it on record that in his opinion the Celtic Irish even still give evidence that they are the descendants of a southern people. Nemedians, Fírbolgs, Tuatha de Dananns, and Scots are reported to have successively planted themselves in an island which before their coming was probably the home of an Iberian people. What may be called the authentic history of Ireland begins with the life and the career of St Patrick. Patrick was born in Scotland, and in his early youth he was carried as a slave to Ireland. He escaped to Rome, and rose high in the service of the then united church. Somewhat early in the 5th century he returned to Ireland with the object of converting the island to Christianity. He accomplished his mission completely, and he even made Ireland the great missionary school for the propagation of the faith all over Europe. At this time Ireland was divided into septs or clans, each sept bearing the name of the head of the family. The septs all owed allegiance to the chief king. All the chieftainships were elective, and during the lifetime of each chief his successor was chosen from the same family, and was called the Tanist. All the land was held by the septs for the benefit of the people, and there was no feudal condition, and no system of primogeniture. Near to the close of the 8th century the Danish sea-rovers invaded Ireland and overran great part of it, and made settlements on the eastern coasts. The Irish chiefs were divided among themselves and could not keep out the enemy, and the Danish occupation lasted for much more than a century. At last, in 968-984, a strong and capable Irish chieftain, Brian Bóroinhe, brother of the king of Munster, defeated the Danes, and, although he did not drive them out of the country, he reduced them to the condition of subdued and submissive residents. Brian now made himself king of Ireland, and for twelve years reigned a successful ruler over a peaceful and prospering country. As he grew old the Danes plucked up spirit again, and got a fleet and an army from their kinsmen across the sea to invade Ireland. Brian, old as he was, proved himself equal to the occasion. He completely defeated the Danes at Clontarf, but was killed in his tent at the end of the battle by one of the enemy, 23d April 1014. There were no more Danish invasions; but the Danish settlers continued to occupy the seaport towns of the east, and in time became absorbed into the common population of the island.

A far more momentous event in the history of Ireland was the Norman invasion (1167-72). This took place in the reign of Henry II. (q.v.), and is another story of Helen of Troy, and of Virginia, and of the fabulous Florida who was said to have been loved not wisely but too well by Roderick the Goth. The king of Leinster carried off the wife of the chieftain of Brehni. The injured husband made war upon his wronger; the king of Leinster was

getting the worst of it, and fled to England, and induced Henry II. to lend him countenance and even help. Henry had before this received a bull from Pope Adrian IV., an Englishman, authorising him to assume authority over Ireland, in order that Ireland might be made more submissive than she was to the ecclesiastical direction of Rome. Henry now took the opportunity offered him by the fugitive king of Leinster, and allowed if he did not authorise a sort of 'Free Companions' invasion of Ireland, and afterwards came over himself to finish the conquest. The Irish kings and chiefs fought fiercely, but the Normans were far better armed, and in fact the story of the Norman invasion of England was told over again in Ireland. Henry organised the country after the Norman fashion as well as he could. He divided the island into counties, and set up the courts, King's Bench, Pleas, and Exchequer in Dublin. He allowed the native Irish, however, to keep to their time-honoured system of Brehon law. He made huge grants of land, the septal property of the island, to his favourite Norman barons, leaving the barons to hold the granted land in the best way they could. So began the great land struggle in Ireland which has lasted down to our own days.

The history of Ireland for a long time after the settlement of the Normans becomes nothing but a monotonous recital of the struggles between the Norman barons and the Irish chieftains, and the struggles between one Irish chieftain and another. The Norman or English barons lived within the enclosure of their own domains and administered affairs on the feudal system. The English territory was known as the Pale. Outside were the Irish, who still strove hard to keep up their own laws, their own customs, and their own civilisation. English law did not extend any of its protection to them. They had no rights which a Norman was bound to recognise. As time went on, however, a curious change was taking place. The English began to be drawn very much towards Irish ways and Irish people. They took to marrying Irish women and speaking the Irish language. This mingling of races alarmed the government in England, and the severest enactments were passed forbidding the adoption by English settlers of Irish names, speech, customs, or garb. One especially cruel edict ordained that any Englishman who married an Irish wife was to be mutilated in a horrible way and then put to death. It was not found possible, however, to put such laws in force often enough to prevent the blending of the races. The Englishmen still married the Irishwomen. The great Norman family of the Geraldines was described as more Irish than the Irish themselves. By the time that Henry VII. had come to the throne the greater part of the island was in the hands of Anglo-Irish chieftains. There was a parliament on the Norman idea sitting in Ireland and illustrating at least the principle of a representative system. Henry VII. seemed inclined at first to leave the Geraldines to manage Ireland in the best way they could; but when the Geraldines supported the cause of Perkin Warbeck and Lambert Simnel, Henry retaliated on them and on Ireland. He sent over Sir Edward Poyning's as lord-deputy, with a strong army at his back and with ample authority to make a great change. Poyning's summoned a parliament at Drogheda, and compelled it to pass the famous measure known as Poyning's Act (1494). This act declared that all English laws should have force in Ireland, and that all legislation in the Irish parliament should be confined to measures which had been first approved of by the king and the Privy council in England. Poyning's Act is an epoch in the history of Ireland.

Henry VII. died. The Geraldines defied the power of Henry VIII. The rebellion of 'Silken Thomas' broke out. 'Silken Thomas,' so nicknamed because of the splendour of his dress, was Lord Thomas Fitzgerald, and he proved himself of stronger stuff than silk. He raised a desperate revolt against the king, but after a hard struggle he was defeated, and he and his five uncles who had taken up arms with him were brought to the Tower of London and hanged. Henry confiscated the church lands in Ireland exactly as he had done in England. A parliament was summoned in Dublin at which, for the first time, some of the Irish chieftains were seen sitting side by side with Englishmen. These were certain of the Irish princes who had agreed to hold their lands as the gift of the crown, to attend the king's parliament and seek justice in the king's courts, to send their sons to be educated in England, and to renounce the authority of the pope. This parliament conferred on Henry and his successors the title of King of Ireland instead of Lord Paramount, the former designation of the sovereign. A weary chapter of struggle followed the death of Henry VIII. Henry had done his best to compel the Irish chieftains and people to give up the faith of Rome and adopt what was now the faith of the majority in England. This was but a new source of bitterness and strife. The great family of O'Neill raised its head higher than ever, and the chief whom, in defiance of English law, it elected to that place, Shane O'Neill, was actually able to make terms with Elizabeth. The Geraldine League was formed. Walter Devereux, the first Earl of Essex, was sent over in 1573 to put down the O'Neills; but although he slaughtered whole masses of them he could not extirpate them. A chronic state of civil war prevailed. After each new rising had been put down there was a new consolidation of territory, a new planting of English and Scottish settlers, and a new attempt to expel or extirpate the native Irish. 'Red Hugh O'Neill' was the most distinguished rebel who had yet appeared in Ireland. He was the grandson of an O'Neill who had consented to accept from Henry VIII. the title of Earl of Tyrone. Hugh O'Neill had been brought up at the court of Elizabeth, and was accounted an ornament of even that most brilliant circle. He was confirmed in his title of Earl of Tyrone. But when he went back to his own country he seems to have found blood thicker than water, for he resumed his ancestral title of 'The O'Neill,' and put on all the ways of an independent Irish prince. He did not at first go into open rebellion; but 'rebellion lay in his way, and he found it.' Whether he was driven into it by the intrigues of English agents and officials, or whether he of his own motion struck for the independence of the country, it would not now be easy to decide. He put himself at the head of a great rebellion of the chiefs, and he won a complete victory in Ulster over Sir Henry Bagenal, the lord-marshal. Bagenal himself was killed. There was something romantic about the encounter of these two opponents. Some time before, O'Neill, then a widower, had fallen in love with Bagenal's beautiful sister. His love was returned, and the lady eloped with him and became his wife. The river Blackwater saw her brother's defeat and death. For a while fortune seemed to smile on Hugh O'Neill. Robert, the second and most famous Essex, was despatched in 1599 to defeat him, with the largest army ever sent into Ireland up to that time; but Essex could do nothing. He was out-generalled and outwitted by the Irish chief, and went back to England and his death. Lord Mountjoy, a stronger soldier, was sent to Ireland in his place, and he at last succeeded in defeating Tyrone and putting down

the rebellion. O'Neill had to come to terms, and to renounce all his claims as independent Irish prince. Elizabeth died, and James I. accepted the surrender.

But James had set his heart on getting rid of all the Irish laws and usages of the country, and if possible putting down the Roman Catholic religion. Tyrone and another Irish chief, Tyrconnel, fled from the country which they saw they had no longer the power to maintain, and both died years after in Rome, and were buried there. 'The flight of the earls,' as it is called, left the island completely in the hands of King James. There were again vast confiscations and new settlements. When King Charles succeeded to the throne and came into trouble with his people some of the Irish chiefs thought their opportunity had come. The native Irish in Ulster rose under Sir Phelim O'Neill, not so much against English rule as against the Scotch and English settlers who had been planted there. In that rising, following on the eight years' administration of Strafford (q.v.), occurred what is called 'the massacre of 1641.' So far as one can form any judgment it does not seem as if there was any deliberate and purposed massacre of the Protestants, although it is impossible to doubt that there was a very barbarous slaughtering of Protestants in one place. The struggles of that time indeed show over and over again hideous incidents which can hardly be described as anything but massacres. The question in this case is, was there a conspiracy to massacre the Protestant settlers—was that the conspiracy—or was there a conspiracy for a rebellion, in the outbreak of which a slaughter of a great number of Protestants was a ghastly incident? Mr Goldwin Smith, who certainly is not in much sympathy with Irish historians, gives it as his conviction that the massacre was 'unpremeditated and opposed to the policy of the leaders,' and that in any case it was not so bad as some of the massacres done by the other side. The rising soon became something very like a national rebellion. Colonel Owen O'Neill, nephew of the gallant Tyrone—Owen Roe O'Neill, as he is always called in Irish song and history—came over to lead the struggle. He had won a high place in the Spanish army. At first his arms in Ireland were all successful. A parliament was held in Kilkenny—a national convention—in October 1642, to proclaim and establish the independence of Ireland. The papal nuncio Rinuccini came from Rome to give his counsel and support to the movement. Charles himself favoured the Irish, and made many pledges to them in the hope of getting their help. His hour, however, had come; his struggle was over, and his execution left Cromwell free to take Ireland in hand. The only man in Ireland capable of meeting Cromwell on a battlefield with any chance of success was unquestionably Owen Roe O'Neill; he had already won one victory over the English forces, but before he had time to throw himself across Cromwell's path Owen died. He died so suddenly that the common belief of the Irish people was that he had been done to death by poison. There seems no good ground for assuming anything of the kind; but the death, so sudden, and for the Irish so untimely, made the suspicion and even the belief quite natural. With O'Neill's death was gone the first and the last and the only chance of any success for the Irish movement. Cromwell's march was from victory to victory. He stamped out the rebellion with merciless severity, and then, like all his victorious predecessors, he went in for a re-settlement of the island. Cromwell's was a re-settlement with a vengeance. He seems to have contemplated such a plantation of the whole country with English and Scotch settlers as would render any further rising of the Irish impossible,

and indeed would before very long lead to the positive extirpation of the Catholic Celts. All Ireland, except Connaught alone, was portioned out among the settlers. Connaught was set apart as a sort of reservation into which the unfortunate Irish were literally driven, and where they were cooped up within certain prescribed limitations. Irish women and girls were shipped off in thousands for virtual slavery or worse in our West Indian possessions.

The Restoration brought the Irish little good, for Charles II. was more anxious to conciliate the Cromwellian settlers than to restore the Irish owners. James II. came to the throne, and the Irish Catholics got better treatment, and in consequence showed a very fervour of loyalty to him. They championed him with all their might when he quarrelled with his people and fled from his throne. The Irish were in all these struggles invariably the losers. They supported Charles I., and brought Cromwell on them; they supported James II., and brought William III. on them. William defeated James at the battle of the Boyne (1690) and on other fields. Limerick held out to the last. It was defended by a brave soldier and true patriot, Patrick Sarsfield—Mr Disraeli once declared in the House of Commons that every true Irishman was proud of 'the sword of Sarsfield'—and William's generals could not capture it. A treaty was made which promised religious freedom to the Catholics and to King James's followers the right to their estates. Then Sarsfield and his soldiers marched out with all the honours of war, and passed away into the service of foreign lands to meet the soldiers of England on many a continental battlefield. The treaty was broken almost immediately after it had been made. King William, who was in Holland at the time of the surrender of Limerick, would have upheld it if left to himself; but the opinion of his English supporters was fierce against the Catholics, and the result of the gallant defence and the honourable and patriotic surrender of Limerick was a series of new penal laws imposed on Ireland with the avowed purpose of extinguishing Catholicism in the island. These laws have in fact ever since been known as 'the penal laws'—*penal par eccellence*.

The two great struggles in Ireland were the religious struggle and the land struggle. The first was part of the great controversy going on all over Europe for the Church of Rome and against it. The main effort of English statesmanship was to extinguish Catholicism in Ireland. The land struggle began with the determination to impose on Ireland a system of land tenure foreign to her habits and traditions, and later on to take the land from the Irish people and give it to the imported settlers. Under William III. the religious struggle became aggravated; the land struggle was not mitigated; and laws were even passed to crush the rivalry of Ireland in various branches of manufacture and of trade. The island sank into wretched poverty, and when the two successive outbreaks of the Stuarts took place, in 1715 and 1745, Ireland, although undoubtedly in deep sympathy with the cause, was too weak to lift a hand in its support. The rights of the Irish parliament were still further curtailed under Anne and under George I. In the reign of George the appellate jurisdiction of the Irish House of Lords over Irish cases was taken away by an act of the English parliament. The Irish parliament was a very poor specimen of a representative institution. Since William III.'s time it was barred against Catholics. To the vast majority of the Irish people its existence might have been a matter of absolute indifference. Yet the sympathies of the country went with the Irish parliament simply because it was

called an Irish parliament, and represented even in name the authority of the Irish people. Gradually there began to grow up in Ireland a popular party led by Protestants, who agitated for the restoration of its independent legislative power to the Irish parliament, and for the reform of that parliament in such a manner as to make it really representative. Grattan and Flood were most prominent in this movement. The war with the American colonies gave an opportunity to the popular party to drive home their demands. A great volunteer force had been organised in Ireland to defend the country, as England could not spare troops for its defence. The volunteers were entirely in sympathy with Grattan, and when the war was over they sustained him in his demands. English statesmen very wisely gave way, and in 1782 the Irish parliament was declared to be an independent legislature—the King, Lords, and Commons of Ireland to make laws for the people of Ireland. An immense impulse was given to popular agitation by this victory. The volunteers were disbanded by Grattan's advice. The new parliament was exclusively Protestant, and was elected by an exclusively Protestant vote. Yet its leaders at once went to work to obtain the emancipation of their Catholic fellow-subjects. Grattan succeeded in obtaining an act to admit Catholics to practice at the bar. He then carried an act to enable Catholics to vote for members of parliament. He went further still; he strove for a measure to enable Catholics to sit in the Irish parliament. In this object he was assisted and encouraged by Lord Fitzwilliam, the viceroy of Ireland. This was too much for George III. The king took fright at the advance made towards full emancipation of the Catholics, and at the very time when the Irish people thought they were near to a peaceful consummation of their hopes, the viceroy was suddenly recalled, and all immediate hope of Catholic emancipation blighted.

There had been a society formed during the agitation called the Society of United Irishmen. It was formed as a merely peaceful organisation to assist Grattan in the carrying of his reforms. It was got up and officered almost exclusively by Protestants; many of them young men of rank and influence, like Lord Edward Fitzgerald. In the anger caused by the recall of Lord Fitzwilliam, and in the despair of any peaceful movement, the United Irishmen became a rebel organisation. The war with France was going on. Napoleon was the rising sun of the French people. Wolfe Tone, a daring young Protestant, went over to France and pleaded the cause of Ireland there. Napoleon took it up merely because he thought an Irish rebellion might be fostered into a diversion in his favour. A French fleet was sent, but was dispersed by a storm like another Armada. A landing was made in one place, but only by a very small force, who were soon defeated and captured. The rebellion broke out in the south, and there was some fierce fighting, but it was crushed. It had indeed, owing to the French failures, been only a series of disconnected local risings. It was crushed with remorseless severity, and deeds of cruelty were perpetrated by the soldiery and the yeomanry who the then commander-in-chief, Sir Ralph Abercromby, deplored and cried out against, but was wholly unable to repress, and which the viceroy lamented and denounced both at the time and after. When the rebellion was put down Pitt thought the condition of things could only be bettered by adopting, with regard to Ireland, the same policy that had been adopted with regard to Scotland, and uniting the two islands under one common parliament. Grattan and his leading colleagues, among whom was Sir John Parnell, fought to the last against the

policy of union, but they were overborne. There can be no doubt that very unscrupulous measures were employed to get a majority of the Irish parliament to pass the act. Some attempt has lately been made to show that the money spent was not spent in purchasing votes, but only in compensation for extinguished proprietorial rights over constituencies. Certainly Lord Cornwallis, the viceroy who carried the Act of Union, was not under any such impression. He understood that he was commissioned to bribe, and he executed his commission faithfully, while he frankly detested the work, and said so. The Act of Union came into force on the 1st January 1801. There had been a promise held out to the Irish Catholics that the union should be a preliminary to their prompt emancipation, but King George would not hear of any such concession, and his ministers did not venture to press it on him. The Act of Union was followed almost immediately by the abortive and hopeless rebellion of Robert Emmet. Then a long dark night of conspiracy, agrarian and political, came on. A great movement was made for Catholic emancipation. The movement was led by Daniel O'Connell, and became successful after O'Connell had defied the law, presented himself as a candidate at the Clare election in 1828, and been returned by a great popular majority. It had become a mere alternative between concession and rebellion, and the Duke of Wellington, like the brave old soldier that he was, declared he had seen too much of war and would not have a civil war, and so prevailed on George IV., and the Catholics were enabled to sit in parliament. The tithe struggle was for a long time a source of the bitterest trouble and the most frequent bloodshed, but a settlement was at last effected by means of which the tithe-collector and the peasant were no longer brought into collision.

In 1842 O'Connell started a great agitation for repeal of the Act of Union, and held 'monster meetings,' as they were called, and at one time seemed to be on the verge of driving the country into rebellion. O'Connell, however, had no such purpose, and when the younger and more fiery of his followers found this out they broke away from him altogether. O'Connell died while the horrors of the great famine of '46 and '47 were still on the land, and in the following year, 1848, the poetic, impassioned, ardently-sincere Young Ireland party broke or drifted into rebellion. The rebellion was easily put down—hardly a drop of blood was shed. But the Young Ireland movement had undoubtedly revived the national feeling in all its intensity. There was a 'Phoenix' conspiracy, as it was called, in 1858, and a Fenian movement in 1867. The existence and the succession of all these movements convinced men like Mr Bright, and afterwards Mr Gladstone, that there was much in the state of Ireland which called for reform and reconstruction. Mr Gladstone set to work with characteristic energy. He disestablished and disendowed the Irish state church—a church which ministered to the spiritual wants of not quite one in five of the Irish population. He passed a series of measures to give better security of tenure to the Irish tenant farmer, to entitle him to compensation for improvements he himself had made if he were to be ejected from his land, and to help to found a peasant proprietary in Ireland. A Land Commission—it might be called a Land Court—was formed which had the power of reducing rents where reduction seemed necessary and rightful, and fixing the rent for a certain number of years. More lately, a Land Purchase Commission was created, the function of which is to assist tenants in buying their farms from the landlords, by an advance, under certain conditions as to repayment, of a large

portion of the purchase money. These measures are in fact part of a great agrarian reconstruction which is still going on in Ireland, and to which Conservative governments as well as Liberal have made contribution. Meantime a fierce struggle had been raging between the peasantry and some of the landlords, the former supported by the popular and powerful Land League. There was much disturbance in Ireland, and Coercion Act after Coercion Act was passed. A Home Rule party had been formed, and out of this party sprang a small but very determined body of Irish Nationalist members who, under the leadership of Mr Charles Stewart Parnell, a descendant of the Sir John Parnell already mentioned, set themselves to force the claim of Ireland on the attention of the English parliament and public by a system of persistent obstruction of all business in the House of Commons. In May 1882 the whole civilised world was horrified by the murder of Lord Frederick Cavendish, newly appointed secretary to the lieutenant of Ireland, and Mr Burke, the permanent under-secretary. The murderers were proved to be a gang of miscreants banded together secretly for the perpetration of such crimes. They were betrayed by some of their own associates, were found guilty, and some of them were executed. The Home Rule agitation went on growing stronger, and at last, when a new Franchise Bill had given a popular suffrage to Ireland as well as to England, the Home Rule party carried off eighty-six seats out of one hundred and three which make up the Irish representation (1885). Mr Gladstone (q.v.) brought in his first Home Rule Bill in 1886, but this was defeated in the Commons by the united Conservatives and Liberal Unionists; a second Home Rule Bill was passed in the Commons, but defeated in the Lords in 1892. Under Mr A. J. Balfour (1887-91) and his brother Gerald (1895-1900), as secretaries, Ireland prospered; and men of all parties and faiths combined in an association to promote dairying, trade, and commerce. The Local Government Act of 1898 has been named above; the Queen's visit in 1900 deserves record, her recognition of the gallantry of the Irish soldiers in South Africa by the permission to wear the shamrock on St Patrick's Day, and the formation of a regiment of Irish Guards. A new departure was made by the Nationalists under Mr O'Brien and Mr Redmond in 1900-1901.

LANGUAGE AND LITERATURE.—The native language is Gaelic—Irish Gaelic as distinguished from Scottish and Manx Gaelic, the three constituting the Goidelic branch of the Celtic language (see GAELIC LANGUAGE AND LITERATURE). The old grammarians sometimes designated their language or departments thereof by different epithets. *Bétra*, now *Beurla*, meaning the English language exclusively, was the general term for 'speech.' A dialect of Gaelic was called *bétra Fionn*—named, it is said, after *Fionn*, a mythical grammarian. This term was afterwards restricted to the 'language of law,' while *bétra bin*, 'fair speech,' was used to designate the 'canon.' According to Cormac *úrbétra* meant 'obscure speech,' and that old lexicographer gives *onn* as the *úrbétra* for 'stone,' *clach* being the *quoth bétra* or common term. Bede informs us that the language of the Picts or *Cruithnig*, to use the Gaelic name, was a separate language; and Cormac, already mentioned, notes *cait* a *dealg* or 'pin' as *bétra Cruithneach*, or a Pictish word. The writer of an old grammatical treatise, preserved in the *Books of Ballymore* and *Liscan* and in MS. I. of the Scottish Collection of Gaelic MSS., professes to give the form of the third person singular of the personal pronoun not merely in the language of the Milesians or Gaels, but also in that of the mythical Firbolgs and Tuatha dé Danann; Gaelic *isise*, *issi*, *issid* (masculine, feminine, and neuter respectively); Firbolg speech *winibus*, *winusi*, *anuor*; Tuatha dé Danann *uol*, *tol*, *trouth*. Elsewhere Cormac gives *toth* as a technical term for the feminine gender and *trouth* for the neuter.

In Ireland the language was less subjected to corrupting influences than in Scotland and in the Isle of Man, and it was more carefully cultivated. The diction of Irish Gaelic is accordingly more copious, and the grammatical forms are fuller. The Norse language, which displaced for a time the native tongue in the Hebrides, hardly took root in Ireland. In the names of three of the four provinces the Norse suffix *ster* appears, but the Scandinavian element in Irish topography as compared with that of the north-west Highlands and the Isle of Man is very small. The English language found its way to the country in the 12th century, but for very many years its advance was slow. As is well known, several of the leading English settlers became ardent students and patrons of the native language and literature. Of the Burkes, the Butlers, the Keatings, and Geraldines it used to be said in this regard that they were *ipsis Hibernis Hiberniores*. Beyond the 'pale' the native laws and ways flourished in full vigour in the 17th century. And even in the more purely English districts Gaelic was commonly spoken. Dr Norman Moore (*Bartholomew Hospital Reports*, xi. p. 146) quotes an edict of the year 1655 ordering all Irish Papists and all Protestants unable to speak the English tongue to leave Dublin before June 20 of that year. But for the last 300 years English has been steadily and with ever-increasing pace gaining ground. The seeds of decline of the native tongue were sown even earlier. The revival of learning which spread over the west of Europe in the 15th century hardly touched Gaelic territory. The impetus given to the cultivation of the native language in Wales and even in the Highlands of Scotland by the Reformation was scarcely felt in Ireland. The views of men in power were hostile to the study of Gaelic. The plantation of Ulster by James I. in the beginning of the 17th century, together with repressive measures of a severe character afterwards adopted, checked the production of native literature and gave an impetus to the spread of English among the people. Within recent years

increased facilities of communication with England, Scotland, and America; the advance of education; the extension of the surlage; the social and political movement of our own day—all contribute to the increasing use of the English language, but without reducing to the same extent the number of persons able to speak the old tongue. In the decade 1871 to 1881 the Gaelic-speaking population of Ireland actually increased. The number who spoke Irish-Gaelic only in 1881 was 64,167, as against 103,562 in 1871; but while there were only 714,313 bilinguals in 1871, the number of such persons increased by 1881 to 885,765. So that the total able to speak Gaelic in 1881 was 949,932, while in 1871 the number of such persons was returned at 817,875. The current decade will very probably show decrease under both heads, but a greater diminution proportionally in the number of persons able to speak Gaelic only than in the class of bilinguals. Many emigrants fondly cherish their mother-tongue in America, and in the United States one or two newspapers print occasional contributions in Irish-Gaelic; but the language is not destined to flourish on its native soil.

The rich literature of Ireland has been preserved to us in inscriptions and manuscript. The oldest inscriptions, found in the south-west of Ireland, are written in a peculiar script called Ogham (q.v.). Native writers made occasional use of this primitive and withal clumsy mode of writing long after they became acquainted with the Roman alphabet, for we find specimens in such MSS. as the Priscian St Gall, and even in quite modern documents, as e.g. in MS. XXXV. of the Scottish collection. A few of the Ogham inscriptions are bilingual, Gaelic and Latin, so that the readings of the mingled Oghams are established. The oldest of them date as far back as 500 A.D. The linguistic forms would suggest even a higher antiquity. Thus, for example, the genitive of masculine O-stems ends in *i*—*magi*, *mailagui*, forms on the same platform with the Old Gaelic inscriptions *Aleguati*, *Druticeni*, and for that matter with classical Latin—*Mavimi*, *domini*. The oldest MS. forms are *maice* and *mailain*, the terminal *i* disappearing as a separate syllable, but becoming incorporated in the preceding syllable in order to preserve the sound of the consonant. This great grammatical change in the short interval between the period of the Ogham inscriptions and the oldest MSS. may, in part at least, be explained by the disturbing influence of the Latin language introduced by the early clerics. Inscriptions in Roman characters are found with greater or less interruption down to our own day.

The Ogham inscriptions have been published, among others, by the late Mr Brash, *Ogham Inscribed Monuments of the Gaoidhel* (1879); the late Sir Samuel Ferguson, in various publications; while the grammatical forms which they exhibit have been explained by Professor Rhys, *Lectures on Welsh Philology*, Lecture vi.; Mr Whitley Stokes, D.C.L., *Beitr. zur Feigl. Sprachl.*, v.; 'Celtic Declension'—*Trans. of Phil. Soc.* (1885), and *Beitr. zur Kunde Indogerm. Sprachen*, xi.; Mons. H. d'Arbois de Jubainville, *Études sur le Druid. Celtique*. The inscriptions in Roman character, chiefly collected and drawn by the late Dr George Petrie, have been published by Miss Stokes, *Christian Inscriptions in the Irish Language* (1872-78).

The MS. literature dates from the end of the 7th or the beginning of the 8th century. The Roman cursive hand of the 5th century was introduced by St Patrick and his companions into Ireland, and has been adhered to with characteristic tenacity to this day. Only eighteen letters were permanently adopted; *a, b, c, d, e, f, g, h, i, l, m, n, o, p, r, s, t, u*. *A* is used to express the numeral 10, occasion-

ally to represent the combination *ca*; *q* stands for *cu*; *k* frequently for *ca* and *cath*, 'battle'; *y* and *z* are met with in one or two loan-words—*ymnon*, a 'hymn'; *Zephon*, 'Stephen.' The oldest preserved MSS. are in Latin. Over 200 such, written by Gaelic scholars before the year 1000, still remain, all with the exception of some half a dozen in France, Germany, Switzerland, and Italy. They were written by the distinguished missionary and scholar Columbanus, his companions and followers, or carried abroad during the 8th and 9th centuries.

Ósú n̄ m̄ar ro do d̄r̄áe n̄s̄ D̄ia an̄ t̄óim̄an, zo

 an̄ b̄ētā r̄ioim̄r̄ē āze.

John, iii. 16 in Irish, as printed by the British and Foreign Bible Society. The following is the translation in Roman letters: Ouis mar so do dhráidhugh Dia an domhan, go dtug se a enghen Meic fe n, ionus goib he chroicreas ann, nach raicadh se a tughá, achd go mbeith an bheatha shiorrudhe aize.

One occasionally finds a Gaelic quatrain on the margin of these MSS., as in the Priscian St Gall, or a short poem on a blank page, as in the Milan and Carinthian Codices. There is a fragment of a sermon in old Gaelic in the town library of Cambray; and still more valuable are the Annotations on the *Book of Armagh*, written in the early part of the 9th century. But the most important remains of old Gaelic are full glosses on about a score of the Latin MSS. on the Continent. Three such are specially noteworthy: a copy of Priscian's Grammar in the library of St Gall; a copy of St Paul's Epistles in the university of Wurzburg; and a commentary on the Psalms of David by Columbanus, now in the Ambrose Library, Milan. The glosses on the Milan Codex are so voluminous that, according to Stokes, a very complete grammar and dictionary could be compiled from them alone.

The oldest Gaelic MSS. now existing were written by the end of the 11th century. To this period belong two beautiful copies of the *Liber Hymnorum*, containing hymns in Latin and Gaelic composed by the early saints, Patrick, Fiace of Sletty, Columba, and others. The writer of *Leabhar na h-Uidhne*, 'the Book of the Dun Cow,' a miscellaneous compilation extracted from earlier books now lost, was killed in the year 1106. The *Book of Leinster*, a large folio of 410 pages, was written before 1167; the *Book of Ballinacree*, also a large folio of 502 pages, and the *Leabhar Breac*, or 'Speckled Book,' containing 280 pages, by the end of the 14th century. Somewhat later are the *Book of Lecan*, a small folio of over 600 pages; and the *Yellow Book of Lecan*, a large quarto of 500 pages. The number of MSS. increases as we come later down. Mons. H. d'Arbois de Jubainville found 953 in Ireland and England (*Essai d'un Catalogue de la Littérature Épique de l'Irlande*, Paris, 1883), the most valuable of which are in the libraries of the Royal Irish Academy (enriched by the Stowe collection, purchased for the Academy by the government), Trinity College, and Franciscan Monastery, Dublin; in the Bodleian, Oxford; and in the British Museum. Many of these MSS. are beautifully written; while several in the ornamentation of their capitals and margins are fine specimens of the artistic skill of the old Gaelic scribes. The contents are of a very varied description, and embrace all departments of literature. A considerable part is translated or adapted. Such are the portions of the legendary history of Greece and Rome found in Gaelic, the destruction of Troy,

the wandering of Ulysses, the story of the Æneid, the life of Alexander the Great, &c.; most of the passions, homilies, and legends, scriptural and ecclesiastical, in the *Leabhar Breac* and other MSS.; and such also is the medical section of the literature. Of native production are history, including biographies, annals, and genealogies; tales, mythological, heroic, legendary; grammars and dictionaries; law; and poetry.

Modern Gaelic literature can hardly be said to exist. The New Testament was published in 1603, and the Old in 1685. A fresh translation of the Pentateuch was made in 1868 by Archbishop Mac-Hale, who also printed the first six books of the *Hail* and a selection of Moore's melodies in Irish Gaelic. The New Testament has been translated anew by Mr Kane into the Munster dialect. Fugitive pieces of lyric verse have appeared from time to time. The *Reliques of Irish Poetry*, published by Miss Brooke in 1789, and the six volumes published by the Ossianic Society (1854-61), are chiefly 'Ossianic.' 'The Gaelic Union' has printed several texts, and publishes the *Gaelic Journal*.

Celtic scholarship dates from the publication of Zeuss's *Grammatica Celtica* in 1853. Valuable work was, however, done by Eugene O'Curry in his *MS. Materials of Irish History* (1861) and *Manners and Customs of the Ancient Irish* (1873); and by O'Donovan in his *Grammar* (1847), his edition of the *Annals of the Four Masters*, and his *Supplement to O'Reilly's Dictionary*. Zeuss's *Grammatica Celtica* (1853; 2d ed., by Ebel, 1871) was the outcome of thirteen years of unwearied work among old Celtic records. Since Zeuss's day scholarship has advanced over the whole field of Celtic studies, in Old Gaulish and in the Brythonic dialects, but chiefly in Gaelic. Ebel and Schleicher and Ziegfried are worthily represented in our day by such men as Ascoli, Nigra, Windisch, Zimmer, Thurneysen, Jubainville, and Loth on the Continent, and among ourselves by Stokes, Rhys, Atkinson, &c. The *Revue Celtique*, founded in 1870 by Gaidoz, reached its tenth volume in 1890. Several other periodicals at home and abroad, notably Kuhn's *Zeitschrift für Vergleich. Sprachf.*, frequently publish important articles on Celtic subjects. Windisch's *Kurzgefasste Irische Grammatik* has twice been translated into English, in 1879. The same scholar has also published *Irish Texts* for the use of students, with a valuable vocabulary. Zimmer (Berlin, 1881) and Stokes published the valuable Würzburg MS., with minor glosses; Nigra, the Turin glosses; and Ascoli, the St Gall and Milan codices. Copious extracts from the Turin and Milan glosses, together with the Gaelic contents of the *Book of Armagh*, the *Liber Hymnorum*, and the *Book of Deer*, with other early texts, were previously printed by Stokes under the title *Goidelicæ* (2d ed. 1872).

Windisch has examined the laws of *anslaut*, vocalic and nasal, and explained initial aspiration and elipsis (the essay has been translated by the late Dr Cameron, and printed in the *Scottish Celtic Review*). Professors Zimmer and Thurneysen have investigated the position of the accent, and its influence on the development of sound and form in Gaelic. The laws of metre have been discussed by Atkinson, Stokes, and the scholars above named; but, in order to attain to full knowledge of the practice of the bards in this matter, it is necessary that the grammatical tract already referred to as preserved in the *Book of Ballymote* and other MSS. be published. In addition to numerous and valuable papers ranging over the whole field of Celtic studies, Stokes has largely added to our knowledge of the Gaelic noun and verb. Valuable materials for a lexicon have been brought together by Windisch in the *Worterbuch* appended to his *Irische Texte*; by Atkinson

in the vocabularies printed with the Homilies, &c., from the *Leabhar Breac*, and with Keating's *Three Shafts of Death*; by Zimmer in his *Keltische Studien*; and by Stokes in the full *Indices Verborum* attached to the numerous texts published by that great scholar. The life and civilisation of the people have formed the subject of separate treatises, as e.g. O'Curry's *Manners and Customs of the Ancient Irish*, and Rhys's *Celtic Heathendom* (Hilbert Lectures for 1886); but more frequently of elaborate introductions and notes to the more important publications, such as Reeves's *Life of St Columba*; the Master of the Rolls' series; Stokes's *Calendar of Oengus*, *The Tripartite Life of St Patrick*, and *Lives of Saints* from the *Book of Lismore*.

The *National MSS. of Ireland*, edited by Gilbert, have been published by government in the Master of the Rolls' series; as also *The Ancient Laws of Ireland* (5 vols.); *The Annals of Lough Cé* (2 vols. edited by Hennessey); *Chronicon Scotorum* (Hennessey); *The Wars of the Goddial with the Gaill* (Todd); *The Tripartite Life of St Patrick* (Stokes). The Royal Irish Academy has printed in fac-simile *Leabhar na h-Uidhreach* (1870), the *Leabhar Breac* (1876), the *Book of Leinster* (1880), and in photolithography the *Book of Ballymote* (1887); and has published the calendar of Oengus the Culdee, edited by Stokes (1880); *Passions and Homilies from the Leabhar Breac*, with vocabulary, by Atkinson (1887); and Keating's *Three Shafts of Death*, by Atkinson (1890). The Celtic Society published among others the *Book of Rights*, edited by O'Donovan (1845), and the *Battle of Mallow*, edited by O'Curry (1855). The Irish Archaeological Society, which had previously issued several valuable works, as e.g. the *Irish Version of Nennius*, edited by Dr Todd (1848), amalgamated with the Celtic in 1854, and the combined societies have published among other important books the *Liber Hymnorum* (2 vols. Todd, 1855-69); the *Life of Columba*, by Adamnan, edited by Dr Reeves (1856); *Irish Glosses* (Stokes, 1860); the *Topographical Poems of O'Dubhagáin and O'Huidhrú* (O'Donovan, 1862); *The Martyrology of Donegal* (O'Donovan); *Cormac's Glossary* (O'Donovan and Stokes, 1868). The Clarendon Press has issued *Saltair na Rann*, edited by Stokes (1883); the *Battle of Ventry*, by Kuno Meyer (1885); and *Lives of Saints from the Book of Lismore*, by Stokes (1890).

IRISH CHURCH. The Irish Church was a branch of the Celtic Church, which comprehended the churches of Galatia in Asia Minor, of Gaul, and of the original Celtic inhabitants of Great Britain and Ireland. The Celtic Church of Gaul necessarily exercised a great influence over the neighbouring islands. Christianity was introduced from the 2d century at least into Britain, where the Celtic Church was so firmly established that it furnished martyrs in the Diocletian persecution, and bishops to the councils of the 4th century. When the Romans left Britain and the Celts retired into Wales, the Celtic Church retired with them, leaving Britain a prey to Saxon paganism. In Scotland Christianity was introduced in 397 by St Ninian (q.v.), a Scottish Celt, but a disciple of St Martin.

St Patrick is called the apostle of Ireland, and his first missionary arrival is fixed at 432; but there were in all probability scattered colonies of Christians along the eastern coast of Ireland by the year 400. We have proof positive of the existence of Christianity in Ireland in the Chronicle of Prosper of Aquitaine, a contemporary of St Patrick. Prosper, under the date of 431, writes thus: 'Palladius was consecrated by Pope Celestine and sent to the Scots believing in Christ as their first bishop,' where the reader must observe that the name Scots or Scoti was till the 11th century exclusively applied to the inhabitants of Ireland. Palladius had not, however, much success in Ireland; he failed to convince the Irish, was driven northwards, and died in North Britain. Thus ended the first formal attempt to convert the

Irish, an effort made too under the direct sanction and authority of the papal see. The very next year (432) St Patrick is said to have arrived on a similar mission; but he was better qualified for his work, and he made his influence felt in every part of Ireland. Gaul in the early part of the 5th century was the great European centre for eastern monasticism. At the very time that St Patrick landed in Ireland from Gaul there was a most active and continuous intercourse kept up between Gaul and St Jerome at Bethlehem, Nitria, and the monasteries of the Thebaid in Egypt. It is to be expected, then, that the Christianity introduced by St Patrick would exhibit traces of its eastern and especially of its Egyptian origin. The architecture and ecclesiastical arrangements of the early Irish Church have therefore many features in common with the East. The monks of Nitria and of the East were generally solitaries dwelling each in his own cell, even when living in a community and under an abbot. The Irish monks were solitaries too, and down to the present day their beehive huts, constructed so as to secure the least possible comfort for the inhabitants, remain all along the western coast of Ireland. The churches in Ireland are often grouped in sevens and placed within a cashel or stone fortification. So they are in Egypt (Butler, *Coptic Churches*, i. 14). The Irish monks, like the Egyptian, loved solitude and the desert, as the name Desert, Disert, or Dysert, which forms a principal factor in many Irish names, proves. The round towers, too, though not so old as St Patrick's time, came to Ireland from the East through Gaul and Ravenna.

The interval between the arrival of St Patrick and the invasion of Ireland by Strongbow and the Anglo-Normans (1169-72) is a celebrated one in the history of the Irish Church. The 6th and 7th centuries are its best-known epoch, for it was then that St Columba and St Columbanus lived and worked. The Irish Church at that time was the great missionary church of Europe. St Columba was its first great missionary. He was the apostle of the Scottish Highlands, and he summoned to his aid when dealing with the Picts two celebrated Irish saints—Caius the patron of Kilkenny, known in Scotland as Kenneth, and Congall, the founder and first abbot of Bangor in the County Down. St Columbanus (q.v.) preached and taught in Gaul and Burgundy, in Switzerland, and in northern Italy. Other missions were those of Aidan, Colman, Finan, Cedd, and many others in northern and central England; of Virgilius, Marianus Scotus, Cataldus, Fiaccra, Fridolin, and several others in various parts of the Continent, down to the 12th century. All these men were not only great missionaries, but also, viewed by the standard of that day, great scholars. Virgil, the geometer and first bishop of Salzburg, was the first of moderns who taught the doctrine of the earth's sphericity and of the existence of the Antipodes. Columbanus upheld the old eastern cycle against Gaul and Rome combined, Sedulius and John Scotus Erigena knew Greek when a knowledge of it had died out elsewhere in the West.

This ancient church was monastic and yet episcopal. It was episcopal but not diocesan; its highest order were bishops but not prelates. The prelates or rulers were the heads of the monasteries, who might be bishops but were most often mere presbyters and abbots. St Patrick and the early missionaries from Gaul found Ireland intensely tribal. Every modern barony, of which there are some hundreds in Ireland, represents an ancient sept or independent jurisdiction. Every ancient diocese, some thirty or so in number, represents an ancient kingdom, or at least an ancient tribe. The earliest missionaries attached themselves to tribes,

who looked to the monasteries and specially to the first founders of the monasteries, regarding them as the apostles of Ireland. But these missionaries had received Christianity in an episcopal shape, and so they retained it. The abbot exercised jurisdiction over all persons and ranks within his community. But the bishop or bishops who might be resident in the monastery or within its reach exercised episcopal functions, ordaining even the abbots themselves, and celebrating the eucharist in their presence. In the controversy as to the relation towards Rome of the early Irish Church some have insisted that St Patrick was simply a papal emissary. Others have insisted upon his complete independence. There cannot be much doubt, however, that Rome and Ireland were for long divided upon important questions. The controversies of the 7th century with respect to the mode of baptism, the keeping of Easter, and the method of the tonsure prove that, while the Irish Church of that date looked up with the greatest respect to the city where the blessed apostles Peter and Paul had suffered, yet she claimed independence in all matters of doctrine and ritual. The Celtic Church, whether in England, Ireland, or Scotland, made a stubborn resistance to Roman claims. In England and Scotland the resistance collapsed at an earlier period. But in Ireland the ancient national opposition to papal claims did not cease till the Synod of Kells in 1152, and of Cashel in 1172.

As to the ritual of the Celtic Church we have not much information. No ancient service-books have survived in Ireland, though a large number of manuscripts belonging to the Celtic period exist in the Dublin libraries; they are almost all, however, transcripts of the Gospels, as the Book of Kells, or of the New Testament, as in the Book of Armagh. The *Antiphonarium Benchocense* and the Book of Hymns which Dr Todd published in the Irish Archaeological series do not contain the liturgy properly so called—i.e. the service for the Holy Communion. It is most likely, however, that the missal of the Celtic Church was in the main identical with that of the other churches of the West, though there were special local usages most abhorrent to the ideas of the Roman party, till in 1172 the Council of Cashel finally established throughout Ireland conformity with the Church of England. There are two other points connected with the Church of Ireland which have often raised discussions—viz. the round towers and the Culdee system. But Dr Petrie has proved that the round towers are of Christian origin, that they were always connected with monastic establishments, and used partly as bell-towers and partly as places of refuge and defence during the wars of the Danes; while Bishop Reeves has shown that the Culdees (q.v.) were spread all over the Celtic Church, and were only the ancient Celtic monks in a state of corruption.

The Roman system was striving for superiority in Ireland from the 7th till the 12th century. Malachy, Archbishop of Armagh (1134), saw that the ancient Celtic system was hopelessly corrupt. He visited St Bernard of Clairvaux, and could not but be struck by the contrast which his own church presented, devoid of architecture, order, or discipline, the prey of every rude and hostile chieftain, when compared with the Roman system in Gaul, where every rank was duly graduated, every order exercised its due functions, and the laity were humbly submissive to ecclesiastical decrees. St Bernard also about 1140 sent the Cistercians to Ireland, and they became the chief agents in reducing the Irish Church beneath the yoke of canonical obedience. The Cistercians brought notions of material civilisation, especially as regards agriculture and architecture, almost hitherto unknown; for, though the Celtic Church

had cultivated literature and scholarship, the really ancient Celtic churches and monasteries were all of the humblest description so far as their architecture was concerned. Here and there indeed in Ireland, when the Cistercians came, a few specimens of architecture of a highly ornamental type called Hiberno-Romanesque were scattered; but it was the Cistercians who made splendid churches and monasteries fashionable in Ireland. The Cistercian monasteries rapidly spread as Anglo-Norman power advanced all over the island. Ireland within one hundred years after the invasion was more thoroughly conquered than she was three centuries later. The year 1250 saw the king's writ far better respected in Kerry or in Donegal than it was in the reign of Elizabeth, and wherever the Anglo-Norman barons settled they brought the Cistercians with them. De Burgh built St Thomas's Abbey in Dublin in honour of Thomas-a-Becket; De Laey, Bective Abbey, overhanging the Boyne near Navan; Strongbow, the Marshals, and their friends erected Jerpoint and Imbrody in the south; the De Courveys Newry and other abbeys in the north. The Cistercians assisted in other directions as well. The Synod of Cashel met in 1172 under the presidency of Christian, Bishop of Lismore, the papal legate of that day, and passed eight canons, enforced the payment of tithes, regulated the work of catechising and of baptism, established the Roman table of affinity in matrimonial matters, and decreed uniformity of worship throughout England and Ireland. From the date of this synod the canon law, as it was received in England, became law in Ireland. The last Celtic Archbishop of Dublin, Laurence O'Toole, died in 1180. The next archbishop, John Comyn, was an English courtier, nominated by Henry II., and from Laurence O'Toole till the Reformation no Irishman was ever Archbishop of Dublin.

The Anglo-Normans whenever they had power strove completely to exclude the Celts from ecclesiastical benefices, and whenever the Celts had power they strove to exclude the Anglo-Normans. In fact, from 1172 till 1540, there were two churches in Ireland, one Anglo-Norman, the other Celtic, bound together by the one tie, the papal supremacy. This hostility between Celt and Anglo-Norman appears again and again. Prior to 1220 the Anglo-Normans prohibited the admission of Irish clerks into monasteries or benefices under English dominion. The pope rebuked this exclusive spirit in bulls issued in 1220 and 1224. Later in the same century the prelates of the Celtic portion of the church retorted with a decree prohibiting the admission of English clerics into parishes or monasteries under their jurisdiction. This spirit of division was embodied in the Statute of Kilkenny (1365), which peremptorily forbade the admission of Irish clerks into any benefice where English rule prevailed; and it continued to be the practical rule followed in all higher promotions till long after the Reformation. Dublin and Kilkenny were the great seats of Anglo-Norman power from 1172 to 1540. Both these districts are full of monuments of English church building, following exactly the model of coeval English architecture; while one must penetrate far into the mountains of Wicklow, or else depart westward into the great central region of bog and morass, before a glimpse can be had of true Celtic architecture.

While, however, there was this internal national division in the Irish Church during this period, the doctrine, the ritual, and government of the church were uniform. The papal supremacy was universally accepted; the royal supremacy was equally respected. Throughout every part of Ireland, no matter how Celtic, whenever a bishopric fell vacant, license to elect was first humbly sought

from the crown of England. And this was no empty ceremony, for whenever the see was of sufficient value the crown also took good care to signify its pleasure as to who should occupy it. The four archiepiscopal sees, Armagh, Dublin, Cashel, and Tuam, were almost always filled by Anglo-Normans. The Irish Church thus ceased to be a missionary and a learned and became a merely political church.

The national hatred which prevailed between the Anglo-Norman and Celtic portions of the Irish Church between 1172 and 1540 explains the history of the Reformation period. The English portion of the population naturally followed the changes in England, and the Celts as naturally held all the more firmly to the papal supremacy and the old state of things which had now become synonymous with hostility to England. Romanism and nationalism became now and henceforth close allies in Ireland, though previously the pope had been almost always found hostile to the Celts. During the years between 1528 and 1600 the course of change in England was simply reflected in Ireland. Archbishop Alan, an English ecclesiastic who occupied the see of Dublin in 1528, was a friend of Wolsey; and he followed closely his patron's footsteps. About 1528-36 forty of the smaller Irish monasteries were dissolved by him. In 1536-38 the remainder were suppressed and their property granted to the king, who disposed of it to various noblemen and courtiers. In a parliament assembled at Dublin in 1537 the act of the king's supremacy in Ireland was enacted, while in 1542 Henry VIII. was declared king of Ireland, his legal title being previously Dominus Hiberniæ. The work of reformation now advanced *pari passu* in England and Ireland. During the reigns of Mary and Elizabeth the Irish Church, so far as it was under English influence, humbly followed the changes in England; under Mary the papal supremacy was acknowledged, and the Latin mass celebrated; under Elizabeth the royal supremacy was alone legal, and the English liturgy was used. In the Celtic districts during Elizabeth's reign a number of bishops commissioned by Rome, aided by several Jesuits, maintained under great difficulties a vigorous opposition to the Reformation. The 17th century saw new elements of religious confusion introduced. The immigration of the Scottish Presbyterians and the settlement of Ulster brought a community into Ireland who disliked the episcopal establishment almost as much as the pope's adherents. They naturally sympathised with the Puritan opposition in England, which culminated in the supremacy of Cromwell. During his vigorous rule, which secured for Ireland a greater amount of peace than she had long known, the episcopal establishment was subverted, and an establishment of a congregational type erected in its stead. On the Restoration the episcopal establishment was restored in greater splendour than ever.

The Roman Catholics now began to consolidate their organisation, establishing a regular succession of resident bishops and clergy throughout the whole country. After the Revolution of 1688-91 a series of stern enactments commenced, which grew more and more severe till the reign of George II. These penal laws were directed against the Roman Catholics, partly as adherents of the Pretender and partly in revenge for the persecution of the Huguenots (q.v.), many of whom took refuge in Ireland. They began to be relaxed during the earlier half of the reign of George III. In fact all through his reign the Roman Catholic Church exercised openly all its functions and maintained a regular episcopal succession. In 1829 the act of Catholic Emancipation (q.v.) was passed, which swept away

all disabilities affecting the secular clergy of the Church of Rome, though still retaining certain restrictions upon the regular orders. By the act of Disestablishment, passed 26th July 1869, the state has separated itself as far as possible from interference in the affairs of any branch of Irish Christianity. The former Established Church is now governed by a general synod, which meets annually in spring, composed of the bishops and representatives of the clergy and laity; while the Roman Catholic Church is ruled, as formerly, by the bishops acting under the direction of the pope. Irish Presbyterianism, dating from 1613, prevails especially in the eastern parts of Ulster. The Presbyterians of Ulster were till 1869 endowed with a *Regium Donum* (q.v.). The organisation of the Presbyterian Church dates from 10th June 1642, when the first presbytery was established in Carrickfergus.

See, among older authorities, Ussher's Works; Sir James Ware's Works (ed. Harris); Colgan's *Acta Sanctorum Hib.*; *Annals of Four Masters*, and works in Roll-series, as *Chronicon Scotorum* and *Annals of Lough C.*. In the 19th century, Todd in his *Life of St Patrick*, and R. King in his *History of the Irish Church*, maintain the Protestant view; Cardinal Moran, in *Essays on the Early Irish Church*, the opposite view; Lauigan, in his *Ecclsiastical History of Ireland*, an intermediate position. Dr Reeves in his *Abbot's Life of Columba* and other works has thrown floods of light on the subject. Other authorities are E. Hogan, S.J., *Documenta de S. Patricio*; Whitley Stokes, *The Tripartite Life of St Patrick*; Warren, *Celtic Liturgy*; Skene, *Celtic Scotland*. G. T. Stokes in *Ireland and the Celtic Church* (1886), and *Ireland and the Anglo-Norman Church* (1889), maintains the independence of the Irish Church; Canon Bellesheim in his works on the history of the Catholic Church in Scotland (1888) and in Ireland (1890) defends the opposite view. See also Bishop Healy of Clonfert, *Schools and Colleges of Ancient Ireland* (1890); Wasserschleben, *Die Irische Kanonensammlung* (1885); Olden, *The Holy Scriptures in Ireland One Thousand Years Ago* (1888); T. K. Abbott, *Versio Ante-Hieronymiana*; Gilbert, *Facsimiles of the National MSS. of Ireland*. For the more recent history: Mant, *History of the Church of I.*; J. T. Ball, *History of the Reformed Church in I.*; Hogan, *Hib. Ignatiana*; Reid, *History of the Presbyterian Church in I.*; Cotton, *Fæsti Eccl. Hibern.*; D'Alton, *Archbishops of Dublin*; Irwin, *Irish Presbyterianism* (Lond. 1890).

Ireland. SAMUEL WILLIAM HENRY, the author of the notorious Shakespeare forgeries, was born in London in 1777, the son of Samuel Ireland, a dull and credulous, but honest dealer in old books and prints, and author of a few books of travel illustrated by himself. After some years' schooling in France, the boy was apprenticed at seventeen to a London conveyancer, and ere long was tempted by his father's unintelligent enthusiasm for Shakespeare to forge an autograph of the poet on a carefully-copied old lease. His audacity grew with the growing credulity of his dupes, and ere long locks of hair, private letters, annotated books, &c. were plentifully produced, and all inquirers into the how and the where fibbed off with lying explanations. Boswell, Wharton, Dr Parr, and hundreds more came, saw, and believed; but those, like Malone, really qualified to judge denounced the imposture almost from the first. Ireland's audacity now reached the folly of producing a deed of Shakespeare's bequeathing his books and papers to a William-Henry Ireland, an assumed ancestor. Next a new historical play entitled *Fortiperna* was announced, and carefully concealed until its production by Sheridan at Drury Lane. It was vapid, worthless, and un-Shakespearean, and was hopelessly damned at once, and this fate nipped in the bud the growth of a projected series of historical plays, of which indeed that on Henry II. had already been written. The meanness of the impudent young scoundrel's father at length getting the better of his credulity, he demanded from his son a satis-

factory explanation of the source of the papers, and the young man was forced to confess his villany. He published his confession in a tract in 1796, and more fully in his *Confessions* in 1805. The father's death in 1800 was supposed to have been hastened by his shame, and the son soon sank into obscure poverty, eking out a miserable living as a bookseller's hack, till his death on 17th April 1835.

Ireland Island, one of the Bermudas (q.v.).

Irenæus, one of the most important of the ante-Nicene Christian writers, was probably born near Smyrna, in Asia Minor, between 120 and 140, and in his early youth was acquainted with Polycarp; but he is known in history solely through his connection with the Græco-Gaulish Church of southern France, of which he was a bishop. He was a priest of the church of Lyons, under the Bishop Pothinus, upon whose martyrdom, in the persecution of Marcus Aurelius, in 177, he was himself elected to the same see, which he continued to govern for twenty-five years. Gregory of Tours states that he suffered martyrdom in the persecution under Severus in 202; but this is probably a mistake. His day is the 28th of June. Irenæus was a devoted and successful missionary bishop, but his name is associated chiefly with his activity in opposing the Gnostics, and especially the Valentinians, and with his attempts to prevent a rupture between the Eastern and Western Churches over the question of the day on which Easter was to be kept. The only work of his which has come down to us, except a few fragments, is his treatise *Against Heresies*; and even that, except parts of the first book which are preserved in quotations in Hippolytus and Epiphanius, we have only in a barbarous Latin version. It is in five books, the first two describing and criticising the tenets of various sects, Gnostic and Ebionite, the last three setting forth the orthodox Christian belief. The first edition of this work was published by Erasmus (1526), from three MSS. which have since been lost. The best editions are those of Stieren (Leip. 2 vols. 1851-53) and Harvey (Camb. 1857). There is a translation, including the fragments, in Clark's *Ante-Nicene Library*. An able examination of Irenæus' opinions will be found in Dr Werner's *Der Paulinismus des Irenæus* (1890).

Irene, a poor orphan girl of Athens (born about 752), whose beauty and talents excited the admiration of the Emperor Leo IV., who married her in 769. After the death of Leo in 780 she ruled as regent during the minority of her son, Constantine VI. Banished to Lesbos in 802, she died there the next year. The Greek Church, on account of her zeal for image-worship, counts her among its saints. See BYZANTINE EMPIRE.

Ireton, HENRY, an English general of the period of the Commonwealth, was the eldest son of Gorman Ireton, of Attenborough, Nottingham, and was born in 1611. He studied at Oxford and at the Middle Temple, London, and on the breaking out of the Civil War offered his services to the parliament. His connection with Cromwell, whose daughter Bridget he married in 1646, greatly advanced his interests. At Naseby he was taken prisoner by Rupert, but Cromwell's charge set him at liberty. Ireton was one of the most implacable enemies of the king, and signed the warrant for his execution. He accompanied Cromwell to Ireland, and in 1650 became lord deputy. On 26th November 1651 he died of the plague before the walls of Limerick. From Westminster Abbey his remains were transferred at the Restoration to Tyburn.

Irideæ, or IRIDACEÆ, a natural order of endogenous plants, mostly herbaceous, with bulbous, tuberous, or creeping root-stocks; a few are some-

what shrubby. The leaves are generally sword-shaped, in two rows, and *equitant* (so placed that one seems to ride on the back of another). The perianth is 6 partite, coloured, often very beautiful, in some regular, in others irregular. The stamens are three, with anthers turned outwards. The ovary is inferior; there is one style, with three stigmas, which are often petal-like, and add much to the beauty of the flower. The fruit is a 3-celled, 3-valved capsule. About 700 species are known, of which the greater number are natives of warm countries. They are particularly abundant in South Africa. A few are British. Iris, Gladiolus, and Crocus are familiar examples of the order. Acridity is a prevailing characteristic, and some species are medicinal; but the roots and root-stocks of some are edible.

Iridescence, the sheen of mother-of-pearl and other objects possessing a finely-grooved surface. It is due to Interference (q.v.) between the waves of white light reflected from different levels in the grooving; some of the wave-lengths are more completely abolished by interference than others are; the result is that the residual vibration which reaches the eye contains a preponderant proportion of the rays which have been less affected by interference, and the reflected light accordingly presents colours which vary according to the angle of reflection.

Iridium (sym. Ir, atomic weight 192.5—sp. gr. 22.38) is one of the so-called noble metals. It is occasionally found native and nearly pure in considerable masses among the Uralian ores of platinum, but is usually combined with osmium as an alloy in flat scales. It is a very hard, white, brittle metal, which may be melted by the oxyhydrogen blowpipe, or by the heat of a voltaic current. It is malleable at a white heat. In its isolated form it is unacted upon by any acid, or by aqua regia, but as an alloy it dissolves in the latter fluid. It forms two oxides, Ir_2O_3 and IrO_2 , and three series of salts distinguishable by their colours, usually much less soluble than the corresponding platinum compounds. Three sulphides and chlorides are obtainable. Iridium may be fused with phosphorus, becoming as hard as before, and is used for pen points, contact points in telegraphy, and wearing parts of scientific instruments. Iridium was discovered by Descotils and by Tennant in 1803.

Iris (originally a personification of the rainbow), the messenger of the gods in the *Hind*, an office which belongs to Hermes in the *Odyssey*, was daughter of Thaumas and Elektra, and sister of the Harpies. In the earlier poets she is a virgin goddess, but later writers make her wife of Zephyrus, and mother of Eros. She is frequently represented on vases and in bas-reliefs as a youthful winged virgin, dressed in a long tunic, with a herald's staff and a pitcher in her hands. The broad coloured ring in the eye is called the Iris (see EYE). Iris is also the name of one of the Planetoids (q.v.), discovered in 1847.

Iris, or FLOWER-DE-LUCE, a numerous genus of plants of the natural order Iridaceæ, having the three outer segments of the perianth reflexed, the three inner arched inwards, and three petal-like stigmas covering the stamens. The species are widely spread over the northern hemisphere. The Yellow Iris or Corn Flag (*I. pseudacorus*) is abundant throughout Britain, and is readily distinguished from the Stinking Iris (*I. foetidissima*) by its larger and bright yellow flowers. The latter has violet-blue or rarely pale yellowish-white flowers, and the leaves smell disagreeably when bruised. The flowers of most of the species are beautiful. Some of them have received much attention from florists, particularly *I. siphnioides*, sometimes called Spanish

Iris; *I. siphnioides* or English Iris; and *I. germanica* or Common Iris, all European species.

Yellow Iris (*Iris pseudacorus*):
a, seeds.

Many fine varieties have been produced. The Persian Iris (*I. persica*), the Snake's-head Iris (*I. tuberosa*), and the Chalcidonian Iris (*I. sasiama*) are also much esteemed. The Persian Iris is delightfully fragrant. The roots of all these species are annually exported in considerable quantities from Holland. Many other species are of frequent occurrence in flower-gardens.—The fresh root-stocks of *I. pseudacorus* are very acrid, as are those of many other species. Those of *I. florentina*, *I. pallida*, and *I. germanica* are Orris Root (q.v.). Those of *I. dichotoma* are eaten in Siberia; those of *I. edulis* at the Cape of Good Hope.

Irish Elk. See ELK.

Irish Moss. See CARRAGEEN.

Irish Sea, a body of water lying between the north of Ireland and the north of England, with the south-western counties of Scotland on the north. It is connected with the Atlantic on the north-west by the North Channel and on the south by St George's Channel. Between the coasts of Louth (Ireland) and Lancaster the Irish Sea has a width of 150 miles; its greatest length north and south is about the same. Within its boundaries lie the Isle of Man and Anglesey, with Holyhead Island.

Iritis is the term applied to inflammation of the iris. See EYE.

Irkutsk, a government of eastern Siberia, separated from China on the S. by the Sayan Mountains, from Transbaikalia on the E. by Lake Baikal, and bounded W. by Yeniseisk, and N. and N.E. by Yakutsk, occupies an area of 287,061 sq. m. The country is generally mountainous, but produces rye, barley, oats, and vegetables. The most important river is the Angara or Upper Tunguzka (1000 miles), which connects Lake Baikal with the river Yenisei. The Lena and its tributary the Vitim are the rivers that come next in size. Gold, iron, and salt figure foremost amongst the mineral products. Agriculture, cattle-breeding, and the transport of goods to and from China are the chief occupations of the people. The pop. 501,237 in 1897, consists of Burjats, Tungus, and Russians (one-third exiles and forced colonists). The industries are not much developed, consisting

chiefly of brandy-distilleries, with iron-foundries and factories for salt, cloth, and pottery. The towns are Irkutsk, Kirensk on the Lena, Nijnindinsk, and Verkholensk.

IRKUTSK, the capital, on the Angara, is the residence of the governor-general of eastern Siberia and the seat of a bishop. Although 3722 miles from St Petersburg (and 40 from Lake Baikal), Irkutsk is the best-built town in Siberia, with straight, wide streets, and handsome public buildings. It possesses a cathedral, several churches, a public library, a museum of natural history, and other public institutions. The pop., 32,512 in 1875, had increased to 43,962 in 1886; it consists mostly of Russians and Buriats. Irkutsk was founded by a Cossack chief, Ivan Pochobof, in 1652, and obtained town rights in 1686. Owing to its position on the great Siberian highway between China and Russia, it is the commercial centre of Siberia, especially for the tea-trade; the annual value of its trade amounts to about £1,100,000. The Angara constitutes the main highway for goods bound for Kiachta across Lake Baikal, as well as for those coming from eastern Siberia and China for Russia. The communications between Irkutsk and Yakutsk and the northern parts of Siberia are carried on by the river Lena. Irkutsk is an important station on the great transcontinental Siberian railway. A fire in 1879 did damage to the extent of £2,000,000.

Irmin and Irmin Pillars. Irmin was a god of the ancient Germanic tribes, the Hermiones and the Hermunduses. To him were dedicated the so-called Irmin or Irmin Pillars, one of which originally stood at Marsberg in Westphalia, but was destroyed by Charlemagne in 772. These pillars were mostly made of wood, and probably were crowned with an image of the god. They were held in great veneration by the people. 'Irmin's chariot' was a name given to the constellation of the Great Bear.

Itrnerius, the 'Lucerna Juris,' a learned jurist of the 12th century, who was born in Bologna, flourished there as a teacher of the liberal arts, and died under the Emperor Lothair II. before 1140. One of the earliest to devote serious study to the *Institutes* and *Code* of Justinian, he has been (some think without reason) regarded as the founder of the Bolognese school of law. We possess by him some unprinted Glosses, and the so-called *Authentica*, an epitome of the *Novells* of Justinian. His *Forumbarium Tabelliarum*, a directory for notaries, and his *Questiones* are not now extant. His name also occurs in the forms Guarnerius, Warnerius, &c. See the monograph by Vecchio (Pisa, 1869), and the 3d vol. of Ficker's *Forschung. zur Reichs-u. Rechtsgesch. Italiens* (hmsbr. 1870).

Iron, sym. Fe (*ferrum*), atomic weight 56, sp. gr. 7.8 to 7.9; its density being increased by hammering, rolling, &c. *Pure iron* is a chemical curiosity obtainable in the laboratory by reducing pure oxide by charcoal or hydrogen at a very high temperature. A button of the metal thus obtained is white and of perfect lustre, very tough, and much softer than ordinary iron. Its melting-point is higher, so much so that if we attempt to fuse it when exposed to the air it burns before its melting-point is attained.

Ordinary commercial iron is protected from such combustion by the impurities it contains; these being more readily oxidised than the iron itself, while they lower its fusing-point. Carbon, silicon, sulphur, and phosphorus are the most notable of these impurities, but manganese, titanium, calcium, copper, arsenic, and other metals also occur in minute quantities in some samples. The proportions of all these are largest in crude or 'pig' iron, and in ordinary cast iron. They are reduced to a

minimum in wrought or malleable iron. The colour of this is gray or bluish-white; it is hard and lustrous, takes a high polish, is fibrous in texture, and when broken across exhibits a ragged fracture. It requires a very intense heat for its fusion, but before melting passes into a soft, pasty condition, in which state two or more pieces of iron may, by being hammered together, be united or welded so completely as to form, to all intents and purposes, a single piece. At a red heat it may be readily forged into any shape; but at ordinary temperatures it possesses very little malleability, as compared with gold and silver. In ductility it stands very high, being barely exceeded by gold, silver, and platinum; and its tenacity is very great; when combined with a little carbon it stands at the head of all the metals (see STEEL). Its susceptibility to magnetism is one of its remarkable characteristics (see MAGNETISM). At a high temperature it burns readily, as may be seen at the forge, or (more strikingly) when a glowing wire is introduced into a jar of oxygen. In dry air and at ordinary temperatures the lustrous surface of the metal remains unchanged; but in a moist atmosphere the surface rapidly becomes oxidised and covered with rust, which consists mainly of the hydrated peroxide of iron. At a bright red heat iron combines with the oxygen of steam and liberates hydrogen.

Native iron is a rare mineral, found in small grains in some basaltic rocks, and very rarely as thin veins. It occurs as one of the chief constituents of one class of meteoric stones. Its compounds are very widely distributed, more so than any other of the heavy metals. Nearly all of the sedimentary rocks are tinted by its oxides, and we cannot find a handful of soil on any part of the surface of the earth that is free from them.

(a) *Oxides of Iron.*—Iron forms four definite compounds with oxygen—viz. (1) the *protoxide* or *ferrous oxide*, FeO, which is the base of the green or ferrous salts of iron; (2) the *sesquioxide* or *peroxide* or *ferric oxide*, Fe₂O₃, which is the base of the red or ferric salts; (3) the *black* or *magnetic oxide*, Fe₃O₄, which is regarded as a compound of the two preceding oxides; and (4) a questionable compound, *ferric acid*, FeO₃. The *protoxide* cannot be obtained in an isolated state, but it forms the base of various ferrous salts, and combines with water to form a hydrate, FeO.H₂O, which, on the addition of an alkali, falls in white flakes provided the water in which they are suspended contains no free oxygen; otherwise the precipitate is gray.

The most important protosalts of iron, or ferrous salts, are the carbonate, the sulphate, the phosphate, and the silicate. *Carbonate of iron* or *ferrous carbonate*, FeO.CO₂, exists naturally in various minerals, and may be obtained artificially by precipitating a soluble protosalt of iron with carbonate of potash or soda, when the carbonate falls in white flakes. On exposure to the air it absorbs oxygen and gives off carbonic acid, and is thus converted into the hydrated peroxide. *Sulphate of iron* or *ferrous sulphate*, FeO.SO₄.7H₂O (or FeSO₄.7H₂O), is obtained by the solution of iron, or its sulphide, in dilute sulphuric acid; in the former case there is an evolution of hydrogen, and in the latter of sulphuretted hydrogen. On evaporation of the solution the salt is obtained in clear, bluish-green rhomboidal crystals containing seven atoms of water. This salt is commercially known as copperas or green vitriol. *Phosphate of iron* is obtained by precipitating a solution of a protosalt of iron with phosphate of soda, when a white precipitate of phosphate of iron is thrown down. All these salts, especially the carbonate and sulphate, are extensively used in

medicine. *Silicate* and phosphate of iron occur naturally in many minerals.

The *peroxide of iron*, or sesquioxide, Fe_2O_3 , is obtained in an anhydrous form by igniting the protosulphate, and is known in the arts under the names *Cochin*, *Crocus of Mars*, or *Rouge*, according to the degree of levigation to which it has been submitted. It is employed for polishing glass, jewellery, &c., and is also used as a pigment. It occurs both in the anhydrous and in the hydrated form in various minerals. The hydrated peroxide, $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, is obtained by precipitating a solution of a persalt of iron with an excess of potash, ammonia, or alkaline carbonate. It falls as a yellowish-brown flocculent precipitate, which when dried forms a dense brown mass. Rust, as has been already mentioned, is a hydrated peroxide.

The most important of the persalts of iron, or ferric salts, are the neutral and the basic sulphate, whose formulæ are $\text{Fe}_2\text{O}_3 \cdot 3\text{SO}_4$ and $\text{Fe}_2\text{O}_3 \cdot 3\text{SO}_3 \cdot 5\text{Fe}_2\text{O}_3$ respectively, the nitrate, $\text{Fe}_2\text{O}_3 \cdot 3\text{NO}_3$, the phosphate, and the silicate. Of these the neutral sulphate, the phosphate, and the silicate occur in various minerals. The nitrate, which is obtained by the solution of iron in nitric acid, is a useful medicinal agent.

The *black* or *magnetic oxide* is formed when iron is heated in air or in oxygen, or in vapour of water.

(b) *Haloid salts of iron*—the chlorides, bromides, and iodides. There are two chlorides—viz. a protochloride, FeCl_2 , and a perchloride or sesquichloride, FeCl_3 . The latter may be obtained by dissolving peroxide of iron in hydrochloric acid. The tincture of the sesquichloride of iron is much employed in medicine. The protiodide is an extremely valuable therapeutic agent.

(c) There are several *sulphides* or *sulphurets of iron*. The protosulphide, FeS , occurs in small quantity in meteoric iron. It may be obtained artificially by heating iron with sulphur. It is a blackish, brittle substance, retaining in some degree the magnetic properties of metallic iron. It is insoluble in water, but in moist air becomes oxidised into protosulphate of iron. With acids it develops sulphuretted hydrogen. The bisulphide of iron, FeS_2 , is the *iron pyrites* of mineralogists, and the *mundic* of commerce. Under the latter name it is used extensively in the preparation of oil of vitriol. The other sulphides are of less importance.

The *protosalts* and the *persalts*, or the *ferrous* and the *ferric salts*, give totally different reactions with the ordinary tests. The solutions of the former have a pale green colour, while those of the latter are generally of a brownish-yellow colour. Sulphuretted hydrogen gives no precipitate with an acid solution of a ferrous salt, while it gives a milky precipitate of sulphur with a solution of a ferric salt. Potash, soda, and ammonia throw down a gray or green hydrated oxide from the former, which changes to darker green and brown, and a brown hydrated peroxide from the latter. Ferrocyanide of potassium gives with ferrous salts a white precipitate, which soon becomes blue, while with ferric salts it at once produces a blue precipitate, even in a very dilute solution. Tincture of galls (tannic acid) produces no immediate change of colour with the ferrous, but a deep blackish-blue colour (ink) with the ferric salts. Sulphocyanide of potassium produces no change with the ferrous, but gives a deep blood-red tint with the ferric salts. Succinate and benzoate of ammonia produce no precipitate or change of colour with the former, while with the latter, if the solution is not too acid, they throw down pale reddish-brown precipitates.

MANUFACTURE OF IRON.—The increasing use of

iron is a prominent characteristic of the present age, and every day sees some new application of it in the arts of life. Although the most useful of the metals, it was not the first known. The difficulty of reducing it from its ores would naturally make it a later acquisition than gold, silver, and copper (see BRONZE). The reduction of the ore known as the black oxide of iron, however, has been carried on in India from a very early time.

In Europe the rich specular and other ores of Spain and Elba were much used during the Roman period; in Greece, also, iron was known, though, as among the Romans, its use was subsequent to that of bronze. We are informed, too, by the Roman historians that this metal was employed by the ancient Britons for the manufacture of spears and lances. The Romans, during their occupation of Britain, manufactured iron to a considerable extent, as is shown by the cinder-heaps in the Forest of Dean and other places. The rude processes then in use left so much iron in the cinders that those of Dean Forest furnished the chief supply of ore to twenty furnaces for between 200 and 300 years. In those early times the iron ores were reduced in a simple conical furnace, called an *air-bloomery*, erected on the top of a hill in order to obtain the greatest blast of wind. The furnaces were subsequently enlarged, and supplied with an artificial blast. Charcoal was the only fuel used in smelting till 1618, when Dud Dudley introduced coal for this purpose; but, the iron-masters being unanimously opposed to the change, Dudley's improvement died with himself. It was not reintroduced till Abraham Darby, in 1713, employed it in his furnace at Coalbrookdale. But, as this method was not properly understood, the production of English iron declined with the change of fuel, till, in 1740, it was only three-fourths of what it had formerly been. About ten years after this, however, the introduction of coke gave renewed vigour to the iron-trade, and then followed in rapid succession those great improvements in the manufacture which have given to the history of iron the interest of a romance. The introduction of Watt's steam-engine in 1770, the process of puddling and rolling invented by Henry Cort in 1784, and the employment of the hot-blast by Neilson of Glasgow in 1830 have each been of inestimable service. The greatest improvement introduced into the iron manufacture in recent times is the process of Sir Henry Bessemer for the production of mild steel, patented in 1856 (see BESSEMER). The 'Siemens-Martin' method of making steel has also of late come into extensive use.

Iron ores are abundantly distributed over the globe, the chief kinds being (1) magnetic iron ore; (2) red hematite, specular, or red iron ore; (3) brown hematite or brown iron ore; (4) carbonate of iron, including spathic ore, clay ironstone, and blackband ironstone.

The ore richest in the metal is the *magnetic* or *black oxide of iron*. When pure it contains nothing but oxygen and iron, its chemical formula being Fe_3O_4 , which gives 73 per cent. of iron by weight. It occurs in dark heavy masses or black crystals, and is found in the older primary rocks. Sweden is famous for this ore, and for the iron produced from it, which is esteemed the best in Europe. The celebrated mines of Dannemora, in that country, have been constantly worked since the 15th century. Russia, too, has great iron-works in the Ural Mountains, which are supplied with this ore. So also have Canada and several of the American states, as Virginia, Pennsylvania, New Jersey, &c. The rock formations in which magnetic iron ore occurs very rarely contain coal; hence it is locally smelted with wood charcoal, which contains no sulphur.

Red hematite contains a little more oxygen, its formula being Fe_2O_3 , that is to say, 70 per cent. of iron by weight if pure. The best ores actually contain from 60 to 67 per cent. There are several varieties of this ore. The first of these, *specular iron*, so called from its bright metallic lustre, occurs in large and beautiful crystalline masses in the island of Elba, where it has been worked for more than 2000 years, and is likewise found in many other parts of the world. It is of a steel-gray colour, assuming a red tint in thin fragments and when scratched. Another variety is *kidney ore*. Its characteristic form is in large kidney-shaped nodules, with a fine radiated structure. Red hematite is the most abundant variety. It occurs in massive deposits and in thin strata; some specimens are hard, others pulverulent and so soft that when rubbed it coats the fingers with an unctuous smear like plumbago, but of red colour. Its importance has much increased of late owing to its special fitness for making the pig-iron used in the ordinary Bessemer process. This valuable iron ore is found in great abundance at Whitehaven and Ulverstone, in the north-west of England, where splendid masses of it occur, 15, 30, and even 60 feet in thickness. Vast deposits are found in the north of Spain near Bilbao, where it is now largely worked and exported to Great Britain, which in 1890-95 received annually from 2,500,000 to 3,500,000 tons, worth from £2,000,000 to £2,500,000.

Brown hematite, or brown iron ore, is a hydrated peroxide of iron, and has the same composition as red hematite, except that it contains about 14 per cent. of water. It is generally found massive, more rarely crystalline, and a variety occurring in small rounded nodules is called *pea iron ore*. When mixed with earth or clay it forms the pigments yellow ochre and brown umber. Brown hematite is now an important ore in Great Britain. It occurs in different geological formations, chiefly in Devonshire, the Forest of Dean, South Wales, and in the county of Antrim in Ireland; also in an earthy form in Northamptonshire. It is the ore chiefly smelted in France and Germany.

Bog iron ore is an impure variety of brown hematite usually containing phosphorus. It occurs in curious pockets in peat.

Humite is a dark-gray dense rock composed largely of peroxide of iron with varying quantities of titanate acid. It is found abundantly in Norway, and is now in practical use. The black sand found on the north-east shores of Canada, and at Taranaki, New Zealand, is similar, but the oxide of iron is magnetic.

Carbonate of iron, when found in a comparatively pure and crystallised state, is known as *spathic*, *spathose*, or *sparry iron ore*; but when impure and earthy, as *clay ironstone* and *blackband ironstone*. Spathic ore was little worked in England previous to 1851, soon after which it was discovered in Somersetshire. The Erzberg, near Eisenerz, in Styria, is the most famous locality for this ore, where it has been worked for ages. The spathic carbonates which are the richest in manganese have been much in demand to yield the spiegeleisen required in the Bessemer process. In its purest form it contains 48 per cent. of iron; and in colour it varies from white to buff or dark brown, some specimens of it taking a beautiful polish, and looking like marble. The clay and blackband ironstones are essentially mixtures of carbonate of iron with clay, blackband having also a considerable proportion of coaly or bituminous matter. These dull earthy-looking ores occur abundantly in Great Britain. Until lately above one-third of all the ore mined in the country was obtained from the coal-measures, where fortunately both the fuel and the limestone, indispensable for the reduction of

the iron, are also found. The ore occurs as balls or nodules, or in continuous beds.

The following table shows how widely distributed are British ironstones. The last item of English production is especially significant. It represents the poorest and worst of all the workable ores, but, being so easily obtained (mostly in open workings like stone quarries), is very cheap, and, being also near to abundance of coal, is used in the great quantities there stated. It is indeed merely an indurated ferruginous mud containing from 40 down to only 20 per cent. of iron.

Including the ores mined under the Metalliferous Mines Act—ores not directly associated with coal—the iron ore raised in 1878 was 15,726,370 tons. In 1894 it was 12,367,308 tons, valued at £3,190,647; the metal produced was 4,317,472 tons, value £9,999,186. In the United States the production of ore was 7,120,362 (long) tons; in 1889, 14,518,041; while in 1894, the produce of pig iron was 6,657,388 tons, value \$65,007,247. In Germany, 11,406,100 tons of iron ore were raised in 1890, and 12,403,800 in 1894. In 1893, France raised 3,517,438 tons of iron ore; Austria-Hungary, 1,100,000 tons; while Russia produced 1,272,235 tons of pig iron.

The ancient iron-masters were unable to work any but the richest and purest ores, the magnetic oxides and hematites. The above table shows by the price and quantity of the North Riding ores that we are now able to work very poor and very impure material.

The most remarkable and useful property of carbon, that upon which its value as a fuel, &c. depends, is that when remaining at ordinary terrestrial temperature it is exceptionally inert, does not combine with the oxygen of the air or even with pure oxygen, nor with other elementary substances (fluorine perhaps excepted), but when heated it acquires so greedy an affinity for oxygen that it not only burns in air i.e. combines

violently with its oxygen (see COMBUSTION), but will take oxygen away from most of its compounds, notably from the metallic oxides. This action of removing oxygen from oxides of metal and leaving the metal in the reguline or metallic state is called reduction, and the great reducing agent of the metallurgist is heated carbon. Hydrogen acts in a similar manner, and is also used as a reducing agent.

The ancient iron-masters obtained iron and steel by simply heating the purest obtainable oxides of iron with an easily-prepared and nearly pure form of carbon—viz. wood-charcoal. Their furnaces

were of very simple construction, merely a hearth or fireplace in which the ore and the charcoal were mixed together and a blast applied to obtain the necessary high temperature. Such simple iron-making is still practised in India, Burma, Borneo, China, Madagascar, &c., and very fine qualities of iron and steel are thus produced.

Fig. 1.—Catalan or Corsican Furnace.

Space will not permit a detailed description of the various forms of ancient furnaces, but there is one that still survives in Europe which is typical and specially interesting. It is shown in fig. 1, and is known as the 'Catalan' or Corsican furnace. The blowing-apparatus is very curious and effective. *f* is the hearth or furnace with the tuyère or blowing-tube inserted in an opening of the wall. The bottom of the hearth is made of a sandstone that will bear great heat, and is lined with charcoal dust. A pile of rich ore, usually hematite, is placed on this and heaped up over the curved wall opposite the tuyère. The hearth is then filled up with charcoal and covered over with a mixture of charcoal dust and small ore, moistened and matted together. A gentle blast is applied at first, and when the flame bursts through the coating more of the same material is laid over to keep back the main charge until the mass is sufficiently heated for a fair start. Then the blast is turned on fully, and the ore that was piled on the curved wall is pushed down gradually as the lower portion is reduced, and this is continued until a mass of spongy iron, or 'bloom,' is formed. This is drawn out, hammered, and rolled with very primitive machinery. The ancient workers were not acquainted with the use of lime as an artificial flux, and hence the silica of the ore was got rid of by combining with some of the oxide of iron and thus forming a liquid cinder

(see STAG).

The blowing-apparatus or 'trome' shown in

the drawing is used in mountainous countries where streams from high levels are available. The upper tank *a* is erected on a ledge of rock with one end overhanging, in this case supported by a tree-trunk. Connected with the large hole in the bottom is a wooden tube with oblique side openings, *b, b*. This tube terminates at the top of a lower tank *c*, which has an outflow opening at *d*, while its upper part communicates with the tuyère at *e*. The tank is otherwise closed and air-tight. At *a* in the upper tank is a plug to regulate the flow of water into the wooden tube. When water flows down this tube its velocity is of course accelerated as it descends. This acceleration divides the column of water, and the spaces between become more or less vacuous. Consequently air rushes in at *b, b*, is dragged down by the descending water, and cannot return against the stream, but is forced by the rushing water through the narrow passage into the upper part of the lower tank, and there compressed in a degree that admits of regulation by raising or lowering the plug *a*. When the inflow of water is in excess of the outflow, the pressure increases, when the outflow is in excess it diminishes, when they are equal it remains steady, and thus the required variations of blast are regulated.

Modern blast-furnaces are hollow towers ranging from 30 or 40 to nearly 100 feet in height, and with internal capacities varying from 500 cubic feet to upwards of 25,000. The smallest furnaces are those used for smelting the richest and purest ores with charcoal, and, generally speaking, the poorer the ores the larger the furnaces, until we reach the maximum in the Cleveland district of the North Riding of Yorkshire, the metropolis of which is Middlesbrough.

Figs. 2 and 3 show a modern blast-furnace of ordinary dimensions (fig. 2) as seen externally (without its appliances for blast, &c.) and (fig. 3) in section. The external rings are of stout iron, bracing all the masonry together. The interior is lined with firebricks or other refractory material, the thickness of this lining or 'shirt' increasing downwards as the heat increases. Between the shirt and outer brick or stone-work an annular space is usually left which is filled with loose sand or fragments of slag to allow for shrinking or expansion of the interior. The larger furnaces have a double lining with such space surrounding each.

Fig. 2.

Blast Furnace.

Fig. 3.

The internal form is a matter of some practical importance. As shown in the section, the upper part or 'tunnel head,' *a, c*, projecting above the

surrounding gallery, is cylindrical. This part is not added to all furnaces. It merely acts as a chimney. Passing downwards we come to a continuation of this, *c, c*, which is called the 'throat,' the charge being pitched down this from the gallery through the arches or 'tunnels' that are shown in the section. Below this is a long truncated cone, *e, f*, called the 'stack,' extending to the widest part, which is called the 'belly;' this name, another form of the 'hosh' or 'hoshes' (supposed to be a corruption of the German *bauch*), is applied to the lower inverted cone, which extends from *f* to *h, h*, where the blast enters by the tuyères or tuyers (from the French *tuyau* or *tuyère*, which is freely translated in the Black Country to 'two irons,' as there are two iron tubes as shown in section, fig. 4,

Fig. 4.

Fig. 5.

and externally, fig. 5). The outer one is surrounded by a lining of flowing water, which enters at *b* and escapes at *c*. This is to save it from fusion. The blast is thrown in through this by the tube *a*. Below these is the crucible where the melted metal rests on the 'hearth.' The charge of ore, fuel, and lime is but slightly altered in bulk until it reaches the hoshes at *f*, and the downward widening therefore assists its descent

and the clearing of the walls; but below this the combustion becomes so active that rapid contraction of bulk occurs and the furnace is shaped accordingly.

The gallery or 'charging-plate,' *e, d*, is shown in fig. 2 connected with a hydraulic lift, by which the charge is raised to the level of the hill-top. In that which is pictured the trolly-road or tramway, *h, h*, is built up to about half height to meet the rising inner tube of the hydraulic lift at *l*. The materials charged into the furnace are ore, fuel, and flux, varying in proportion with the composition of the ore. The demand for flux is due to the impurities of the ore. Lime is used for this purpose. It combines with the silica, and forms a readily fusible compound, a silicate of lime or lime-glass, which descends with the silicate of alumina, an analogous compound in the clay, and forms the 'slag,' or more properly 'cinder,' which floats on top of the fused iron in the crucible. The old iron-masters who used no such flux lost much of their iron by the combination of its oxide with the silica; hence the iron in the 'Dane cinders' of the Forest of Dean. In most of the modern furnaces the crude limestone is charged with the crude ore. Otherwise the ore is first roasted to expel the water of composition it contains (clay is a *hydrated* silicate of alumina) and the carbonic acid which is combined with the iron, and the limestone is similarly roasted in kilns to expel its carbonic acid. In the tall furnaces with hot-blast these operations are automatically performed in the upper part by the heat escaping from below. Formerly the coal was all coked before charging into the furnace; now raw coal or a mixture of coal and coke is used, and the coking, like the roasting, occurs in the upper part of the furnace. As the charge descends to the hotter and hotter parts of the furnace the oxide of iron, now dehydrated and dissociated from carbonic acid, becomes reduced to the condition of 'spongy iron.' The experiments of Sir J. Lowthian Bell show that such reduction occurs at a lower temperature than was formerly supposed. It is fairly started, if not

completed, before the limestone is fully calcined. The chief reducing agent is the heated carbonic oxide gas that rises from the incandescent mass below. This gas, a compound of one equivalent of carbon with one of oxygen, CO, combines greedily with oxygen when heated, and forms carbonic dioxide (carbonic acid), CO₂. In this case it does so by taking away the oxygen from the oxide of iron. The hydrocarbons formed by the distillation of the coal probably co-operate. The spongy iron thus formed corresponds to the final product, the 'bloom' of the Catalan and other primitive furnaces. The iron itself is pure enough, but is entangled with the earthy impurities of the ore. The bulk of these impurities is finally removed by the flux, but before this occurs another and rather vexatious action occurs at the full and bright red-hot region below. This is described by Sir J. L. Bell as the 'zone of absorption,' for here the spongy iron absorbs impurities that have afterwards to be removed by the puddler. It takes up carbon, silicon, sulphur, and phosphorus from its surroundings, the sulphur and carbon from the coal, the silicon and phosphorus from the ore. These, though mischievous, assist the work of the blast-furnace; they lower very considerably the fusing-point of the iron, the pure spongy iron being practically unfusible in an ordinary furnace. The manner in which the spongy iron appears to obtain its carbon is curious. Carbonic oxide when highly heated (2190 F.) is dissociated into carbon and carbonic acid. One half of a given quantity loses its oxygen and gives it over to the other half. Taking two equivalents of carbonic oxide, containing two of carbon and two of oxygen, the change may be represented thus:

$$\begin{array}{c} \text{O} \\ \diagdown \\ \text{C} \longrightarrow \text{CO}_2 \\ \diagup \\ \text{O} \\ \text{C} \longrightarrow \text{C} \end{array}$$

Sir J. Lowthian Bell, who has devoted an immense amount of costly labour to the investigation of the contents of various parts of the blast furnace, maintains that this dissociation occurs at a much lower temperature in the blast-furnace than in Deville's apparatus, possibly owing to the help of the iron in combining with the flocculent carbon immediately it is thus separated.

After these changes are completed, fusion speedily occurs in the rapidly contracting region of the furnace, and finally the whole contents of the furnace, excepting those which are converted into gases that escape from the top, are liquefied and fall into the crucible as two distinct fluids, the melted crude iron, and the cinder or slag. The latter floats above the metal and runs out over a dam by a specially-constructed orifice. While thus covering the iron it protects the metal from oxidation, and this continues until the metal accumulates sufficiently to reach the 'cinder notch' of the dam. When this occurs the furnace is tapped—i.e. a plug which stopped a channel-hole at the bottom of the crucible is removed, and the molten crude iron flows in a glowing stream down long channels in a bed of sand. Side-channels of moderate length branch out on each side of the main channels, as near to each other as possible, and these are filled with the iron. In the poetic language of the Black Country the main channel is called the 'sow,' and the smaller branching channels the 'pigs.' Hence the well-known name of 'pig-iron.'

The table below shows the composition of pig-iron; the first being the mean of twenty-nine brands of high-class pig, the second of a common Cleveland pig; the analyses made by the writer:

Combined Carbon	0.91	0.80
Graphitic Carbon	1.92	1.90
Silicon	1.81	2.23
Phosphorus	0.33	1.50
Sulphur	0.25	0.27
Manganese	1.28	0.71
Iron by difference	93.50	93.60
	100.00	100.00

Pig-irons are technically described as gray, mottled, and white, and commonly numbered accordingly, commencing with the gray as No. 1, down to No. 8, the extreme white. Gray pig-iron is granular and easily drilled or filed, owing to this structure; white pig is crystalline and very hard, harder than the hardest steel. This difference is mainly due to the different conditions of the carbon. In the gray it is nearly all uncombined or graphitic; in the white, nearly or quite all combined; the mottled is intermediate. It is easy to pick out with a penknife from a good sample of No. 1 pig brilliant scales of graphite, technically described as 'kish.' Good samples of pig-iron are used directly for making castings, or the pig-iron is refined (see below) for this purpose. Such 'cast-iron' is brittle in proportion to the impurities it contains. In its ordinary condition it is neither malleable nor ductile, though small castings of a superior quality of refined iron may be rendered tougher by careful annealing. These 'malleable castings' are now largely used.

One of the important improvements of modern ironmaking is the use of the hot-blast. Very great economy of fuel is thereby effected. A great variety of ovens for heating the blast have been patented. Their essential principle is passing the air through tubes or passages of iron or fireclay that are heated by a flame or hot air surrounding them. The heat is usually obtained by utilising the waste inflammable gases that formerly blazed away to waste from the top of the blast-furnace. For this purpose the tunnel-head (*a, c*, figs. 2 and 3) is cut down, or not built, and the charge is thrown upon a stopper, which is movable in such wise as to drop the charge with little or no escape of the gases

from the interior of the furnace. The most common of these devices is the 'cup and cone,' shown in fig. 6, where *u* is the cup that plugs the opening of the truncated cone above. The charge is pitched into this inverted cone and rests there till the cup is

Fig. 6.

lowered, when it falls around the cup. In the figure the furnace is shown closed. The inflammable gases then descend by the pipe *b* to their destination.

In order to obtain ordinary malleable iron from pig iron the bulk of the impurities are removed by 'puddling' and hammering or squeezing. The old iron masters simply melted the crude iron in a refining furnace or 'finery,' and then subjected it to the action of a blast, which sufficiently oxidised the silicon and carbon. Where these are the only impurities that require removal this treatment is still used; but such severe oxidation fails to remove the sulphur and phosphorus. The refining furnace, which is still used to some extent for the conversion of gray into white cast-iron, or as preliminary to puddling, is shown in section in fig. 7. The pig-iron and coke or charcoal are charged into the space *D*; the blast is driven through the blast-pipes, *C, C*, to the tuyeres, as shown. After starting well with fuel below, the coke continues to burn and the iron to melt, and both are continuously charged, the melted iron flowing down to the hearth below, where the blast strikes upon its surface and oxidises the carbon and silicon, at the same time circulating the fluid metal by its stirring action. If this is continued long enough, a bloom or ball of malleable iron is produced. With less blowing the silicon is for the most part burned out, and the graphitic carbon is caused to

combine by the high temperature attained, and thus 'white iron,' suitable for foundry purposes or for puddling, is produced. In this case the melted iron is run into a shallow hearth, and there allowed

Fig. 7.—Finery.

to cool and throw up a film of silicate, which easily separates from the refined metal below. This is broken up into convenient pieces, and is commonly described as 'plate' iron.

The Bessemer process (see BESSEMER STEEL) is but a modification of this, the difference being that, instead of blowing on the surface, the Bessemer blast is introduced below, and therefore acts more thoroughly.

The puddling furnace, in which the puddling process is conducted, is shown in vertical section in fig. 8, where *f* is the fireplace, *br* the

Fig. 8.—Puddling Furnace, vertical section.

bridge, *b* the bed, *fl* the flue, and *p, p, p, p*, iron pillars supporting the furnace. It is constructed of firebricks, and the whole, excepting the flue, is encased in strong iron plates firmly strapped together by iron rods. When the fire is blazing the flame surmounts the bridge, strikes the arched roof, and 'reverberates' down upon the contents of the bed, and passes along the flue to a short chimney, which is surmounted by a damper plate that may be raised and lowered to regulate the draught. Fig. 9 is a horizontal section with the same lettering, excepting that *s* is added to show the working-door or stopper-hole through which the puddler works. When the roof, walls, and bed of the furnace are moderately heated the puddler 'fettles' his furnace by plastering the bed and sides with a 'fettling' composition, which consists essentially of ground oxide of iron made into a paste with water. Hematite is the best fettling; 'bulldog,' made by roasting refuse cinder, is cheaper, and largely used. Lumps of crude iron are now thrown in, the fire is made up, the doors closed, and damper raised to 'rouse' the whole and melt the charge, which usually amounts to 1½ cwt. Two men work the furnace, the 'forehand' and his 'underhand.' During the melting the underhand turns over and

distributes the lumps with a long iron rod. When the melting is completed a heavier iron bar, flattened and bent at the working end, is used. This is called the 'rabble,' and with it a vigorous stirring or 'rabbling' is kept up. The work is very exhausting, and the men work in turns, the forehand taking the critical part of the process, where greater skill is demanded. As this proceeds the surface of the melted metal becomes further agitated by the bursting of small bubbles; this agitation, at first superficial, deepens and deepens, until the whole mass is seen to be violently seething and

Fig. 9.—Puddling Furnace, horizontal section.

spiriting up flashes of blue flame from the bursting bubbles. This flame is mainly due to the burning of carbonic oxide. The puddler calls this the 'boiling,' and now the forehand works the rabble with great energy. As the rabble becomes softened at the working end and heated where held, it is rapidly plunged into a trough of water, and exchanged for a cool one. Careful observation shows that the puddler not only stirs the fluid, but gropes or *rabblies* along the bottom and sides of the furnace. Presently the melted mass thickens, solid granules are formed amidst the liquid. This the puddler describes as 'coming to nature.' It consists in the separation of infusible iron from the

fusible silicates; the oxidation of the silicon forming glassy silicic acid, which combines with oxide of iron or any other basic material within reach. These solid granules are at a welding heat, and the next business of the puddler is to weld them together, which he does by running off as much as possible of the liquid cinder, and squeezing the granules together into a spongy mass or ball. At this stage he lowers his damper and blocks the draught-hole with lumps of coal, in order to envelop the mass of exposed granular iron in a smoky reducing atmosphere. This prevents ruinous oxidation or 'cutting,' as the puddler calls it. Book-learned critics have pointed to the dense volumes of smoke which then issue from his chimney, and have accused him of ignorant wastefulness in the consumption of fuel. In this case the illiterate black-faced puddler understands the theory and the practice of his work, and the learned fine gentlemen are ignorant of both. The ball is now divided into portable dimensions (usually into three), and is rapidly carried to the hammer, where it is struck lightly at first, but with gradually increasing force as it becomes compressed into shape. The three balls may be united, commonly are, and thus beaten into a 'puddled bar.' During this heating, or 'shingling,' liquid cinder is squeezed from the mass like water from a sponge. More and more is squeezed by subsequent compression in passing the puddled bar through rolls similar to those shown in fig. 10. It first enters the large hole of either the square or the round set, and then while still red-hot passes successively through smaller and smaller openings. In the subsequent working of the iron this squeezing out of the impurities is continued. Thus, if it is made into boiler-plates or thin sheets, the bars made by passing through the rolls are cut into short lengths and 'piled'—i.e. stacked in square bundles, then heated and rolled out, during

Fig. 10.—Rough and Finishing Rolls.

which working more fluid cinder is expressed. By such means the quality is improved up to a certain point, but beyond this mischief is done, for if the reheating is repeated too often the protecting remainder of carbon is removed, and the iron itself then oxidises—'burnt iron' is the result. This is triable, owing to the presence of particles of black oxide in the midst of the iron.

Formerly puddling was regarded merely as a process of oxidation produced by the action of air on the surface, and the puddler's stirring was described as a means of bringing fresh material to the surface. It was afterwards shown that large quantities of oxygen are supplied from below by the reduction of the oxide of iron in the fettling. The writer has tested this theory by excessive fettling with rich hematite and laborious rabbling; and has thereby turned out a weight of puddled bar exceeding that of the crude iron of the charge, the excess being due to the reduced iron from the hematite. But even this is not sufficient to account for the purification from sulphur and phosphorus; oxidation alone will not remove the remainder of these when their quantities are brought down to about $\frac{1}{2}$ per

cent. This has been fully proved by the failure of the fierce blast of the Bessemer converter to do so without also oxidising the iron itself. The writer's explanation of the puddler's success in purifying very bad pig-iron is that his process consists of oxidation *plus* washing; that he washes the granules of iron in liquid and basic cinder, as the laundress washes fibres of cotton, &c. in soap and water. The sulphur and phosphorus are found in the cinder, as the dirt and grease in the soap-suds. The subsequent squeezing out of the residual entangled liquid cinder by hammering, rolling, &c. is, according to this theory, strictly analogous to the *wringing* of the laundress. In connection with this impossibility of removing *all* the sulphur and phosphorus by mere oxidation it is desirable to correct a serious error that is repeated in most of our text-books—*even the best*. This is the statement that wrought iron contains no practically important quantity of carbon. This error is not shared by practical iron-makers who have studied the chemistry of their work. They know that some carbon or silicon, or both, must remain to protect the iron itself from oxidation when heated. It

usually contains about 2 per cent. of carbon, more or less, according to the quantity of silicon, which, being more readily oxidised than carbon, is a still more efficient protector. This is of great practical importance now that the Bessemer and Siemens-Martin processes, formerly used only for making steel, are applied to the manufacture of a malleable iron by pushing the oxidation to its utmost limit. If this limit is exceeded brittleness instead of toughness is the result, and a mistake in this direction involving certain portions of such a structure as the Forth Bridge might be fatal to the whole, as 'nothing is stronger than its weakest part.' For the making of such 'semi-steel,' see BESSEMER STEEL, and STEEL. And see FOUNDING.

Statistics as to the development and present position of iron manufactures will be found in the articles GREAT BRITAIN, BELGIUM, GERMANY, UNITED STATES, &c. IRON IN ITS PHYSIOLOGICAL AND THERAPEUTIC RELATIONS.—Iron is an essential constituent of the colouring matter of the blood-corpuscles of all vertebrate animals; and, according to the best authorities, one part by weight of iron is found in 230 parts of blood-corpuscles, and the total quantity of this metal in the blood of a man weighing 140 pounds is about 38 grains. It is the presence of iron in the blood that communicates to the ashes of that fluid their reddish-brown colour, the iron being found in them as the peroxide. The ashes of hair, of birds' feathers, of the contents of eggs, of gastric juice, of milk, and of most animal fluids, contain traces of iron.

Nothing is known with certainty regarding the chemical condition of the iron in the animal body; it probably exists as protoxide in the venous blood and peroxide in arterial blood. It is introduced into the system with the food and drink, and any excess beyond what is required is discharged with the excrements. It is thus a food rather than a medicine; but when an insufficient quantity is contained in the nutriment, or when from any cause the absorption of the iron contained in the food is interfered with, chalybeate medicines become necessary in addition. The iron that is set free within the system by the constant disintegration of blood-corpuscles is carried out of the system partly by the urine, chiefly by the colouring matter of the bile, which is highly ferruginous, and probably is in part eliminated by the hair. The exact part which the iron plays in the body is uncertain; but it is most probable that the power which the blood-corpuscles possess as oxygen-carriers is mainly due to the presence of iron.

In most forms of Anæmia (q.v.), especially Chlorosis (q.v.), the iron compounds are of incomparably more service than any other remedies. In amenorrhœa, in certain painful nervous affections, and in many conditions of debility the salts of iron are of especial service. They are contra-

indicated in plethora, and in most states accompanied by feverishness. The forms in which iron may be prescribed are very numerous, and vary considerably in their utility, according to the readiness with which they get taken up into the blood. Amongst the most generally used ferruginous medicines may be mentioned reduced iron, the tincture of the perchloride, the saccharated carbonate, the compound iron mixture (containing the carbonate), the sulphate, the tartarate, several citrates (especially the citrate of iron and quinine), &c. A course of Chalybeate Waters (see MINERAL WATERS) may often be prescribed with great advantage when the patient cannot bear the administration of iron in its ordinary medicinal form.

Iron Age, an archaeological term indicating the condition as to civilisation and culture of a people using iron as the material for their cutting tools and weapons. It is the last of the prehistoric stages of progress represented by the series of the three ages of Stone, Bronze, and Iron. But it has to be remembered that this sequence is not necessarily true of every part of the earth's surface, for there are areas, such as the islands of the South Pacific, the interior of Africa, and parts of North and South America, where the peoples have passed directly from the use of stone to the use of iron without the intervention of an age of bronze. In Europe the iron age may be defined as including the last stages of the prehistoric and the first of the protohistoric periods. As the knowledge of iron seems to have travelled over Europe from the south northwards, the commencement of the iron age was very much earlier in the southern than in the northern countries. Greece, as represented in the Homeric poems, was then in the transition period from bronze to iron, while Scandinavia was only entering her iron age about the time of the Christian era. The transition from bronze to iron in central Europe is exemplified in the great cemetery, discovered in 1846, of Hallstatt, near Gmunden, where the forms of the implements and weapons of the later part of the bronze age are imitated in iron. In the Swiss or La Tène group of implements and weapons the forms are new and the transition complete. The early iron age forms of Scandinavia show no traces of Roman influence, though these become abundant towards the middle of the period. The duration of the iron age is variously estimated according as its commencement is placed nearer to or further from the opening years of the Christian era; but it is agreed on all hands that the last division of the iron age of Scandinavia, or the Viking Period, is to be taken as from 700 to 1000 A.D., when Paganism in those lands was superseded by Christianity. The iron age in Europe is characterised by forms of implements, weapons, personal ornaments, and pottery, and also by systems of decorative design, which are altogether different from those of the preceding age of bronze. The implements and weapons are no longer cast but hammered into shape, and as a necessary consequence the stereotyped forms of their predecessors in bronze are gradually departed from, and the system of decoration, which in the bronze age consisted chiefly of a repetition of rectilinear patterns, gives place to a system of curvilinear and flowing designs. But the principal feature that distinguishes the iron age from the preceding ages is the introduction of alphabetic characters, and the consequent development of written language which laid the foundations of literature and historic record.

Handbook), by Worsae (1882); *The Industrial Arts of Scandinavia in the Pagan Time* (South Kensington Handbook), by Hans Hildebrand (Lond. 1883).

Iron Bark Tree, a name given in Australia to certain species of Eucalyptus (q.v.), and particularly *E. resinifera*, or Red Gum, on account of the extreme hardness of the bark.

Ironclads, a term first applied to wooden ships of war strengthened by a more or less complete covering of iron armour-plates. Partial iron defences for war galleys seem to have been in use in the middle ages; the floating batteries used at the siege of Gibraltar in 1782 had bomb-proof roofs and sides, strengthened by leather and bars of iron. Systematic defences of this kind were advocated by numerous writers in France, America, and England, early in the 19th century. But the first regular use of iron armour on the sides of ships was when, during the Crimean war, the French made and sent to the Black Sea floating-batteries with armour $4\frac{1}{2}$ in. thick. In 1858 the French had four iron-plated line-of-battle ships building. The first British sea-going ironclad was the *Warrior* (1860), with $4\frac{1}{2}$ in. armour for the upper deck to the water-line; but, as iron was the material of which the ship was built, 'ironclad' became rather a misnomer. The term is still employed loosely for all armoured ships, turret-ships, barbette-ships, &c., even if the hull and framework are of iron and the armour (which in the *Invincible* is from 16 to 24 in. thick) is faced with steel (as in the *Edinburgh*, *Camperdown*, *Warspite*, &c.). See NAVY, and SHIPBUILDING.

Iron Cross, a Prussian order, instituted on March 10, 1813, by Frederick-William III., to be conferred for distinguished services in war. It was made of iron to commemorate the grim 'iron' period at which it was created. The decoration consists of a Maltese cross of iron, edged with silver, and is worn round the neck or at the button-hole. The order was revived by William I. on 19th July 1870, on the eve of the great war with France. The grand cross, a cross of double the size, is presented exclusively for the gaining of a decisive battle, or the capture or brave defence of a fortress.

Iron Gates. See DANUBE.

Iron Mask, THE MAN WITH THE. The story of the prisoner so called, confined in the Bastille and other prisons in the reign of Louis XIV., has long had a romantic interest for the readers of history. The first notice of him was given in a work entitled *Mémoires Secrets pour servir à l'Histoire de Perse* (Amst. 1745-46), according to which, he was the Duke of Vermandois, a natural son of Louis XIV. and of Mlle. de la Vallière, who, having given a box on the ear to his half-brother, the grand dauphin, had to expiate it with imprisonment for life. The assertion was without foundation, for the Duke of Vermandois died in camp in 1683; but the confidence with which it was made caused a deep sensation, and the romance of Monby, *L'Homme au Masque de Fer*, which immediately followed (Hague, 1746), was read with all the more avidity that it was prohibited. Voltaire, in his *Siècle de Louis XIV.*, treats the anecdote historically. According to him, the prisoner was young, and of a noble figure. In journeying from one prison to another he wore a mask, and was at last transferred to the Bastille, where he was treated with great distinction.

The first authentic information with regard to the Iron Mask was given by the Jesuit Griffet, who acted for nine years as confessor in the Bastille, in his *Traité des différentes Sortes de Prisons qui servent à établir la Vérité dans l'Histoire* (Liège,

1769). He brought forward the MS. Journal of Du Jonea, the lieutenant of the Bastille, according to which Saint-Mars arrived, on the 18th September 1698, from the Isle de Sainte-Marguerite, bringing with him in a litter a prisoner whom he had already had in custody at Pignerol. The prisoner's name was not mentioned, and his face was always kept concealed by a mask of black velvet. The journal mentions his death on the 19th day of November 1703, and that he was buried in the cemetery of St Paul. This is confirmed by the register of burials for the parish of St Paul's, where the prisoner is mentioned under the name of Marchiali.

After long silence Voltaire returned to the subject in his *Essai sur les Mœurs*, but he brought forward nothing new. In the seventh edition of the *Dictionnaire Philosophique* he related the story anew, under the head *Anc*, corrected his errors as to time from the journal of Du Jonea, and concluded with the assurance that he knew more about the matter than Griffet, but chose, as a Frenchman, to be silent. An addition to the article, apparently by the editor of the work, freely states the opinion that the Mask was an elder brother of Louis XIV. The writer declares that Anne of Austria had this son by the Duke of Buckingham, and being thus undeceived as to her supposed barrenness, brought about a meeting with her husband, and in consequence bore Louis XIV. Louis is held to have first learned the existence of this brother when he came of age, and to have put him in confinement, to guard against any possible unpleasant consequences. Saint-Michel published a book in 1790, in which he relates the story of the unfortunate being, and points to a secret marriage between Queen Anne and Cardinal Mazarin. What is remarkable is that not the court but Lamoignon continued to manifest an interest in the matter, and took every means to keep the identity of the prisoner in the dark. When the Bastille fell the prisoner's room was eagerly searched, and also the prison register; but all inquiry was vain.

The Abbé Soulavie, who published *Mémoires de Marshal Richelieu* (London and Paris, 1790), tries to make out from a document written by the tutor of that unfortunate prince that the Iron Mask was a twin-brother of Louis XIV. A prophecy had announced disaster to the royal family from a double birth, and to avoid this Louis XIII. caused the last born of the twins to be brought up in secret. Louis XIV. learned of his brother's existence only after the death of Mazarin, and that brother, having discovered his relation to the king by means of a portrait, was subjected to perpetual imprisonment. This view of the matter was the one almost universally prevalent till the time of the Revolution. It is also followed in Zschokke's German tragedy, and in Fournier's drama, founded on the story. In Grimm's correspondence may be found the legend of the birth of a twin-brother of Louis XIV., but history avers that seventeen persons were present and witnessed the delivery of the queen of one male infant only. As regards the intrigue of Anne of Austria with the Duke of Buckingham the dates make the supposition absurd, as forty-eight years elapsed between their *adulter* and the first imprisonment of the Mask in Pignerol.

The first conjecture of what till recently seemed to be the truth is contained in a letter dated 1770, written by a Baron d'Heiss to the *Journal Encyclopédique*. The same is repeated by Louis Dutens in his *Intercepted Correspondence* (1789), who declares that there is no point of history better established than the fact that the prisoner with

the Iron Mask was a minister of the Duke of Mantua. This minister, Count Matthioli, had pledged himself to Louis XIV. to urge his master the duke to deliver up to the French the fortress of Casale, which gave access to the whole of Lombardy. Though largely bribed to maintain the French interests, he began to betray them; and Louis XIV., having got conclusive proofs of the treachery, contrived to have Matthioli lured to the French frontier, secretly arrested, 23d April 1679, and conveyed to the fortress of Pignerol, which was his first prison. The conclusion of D'Heiss and Dutens, that Matthioli was the Iron Mask, though acute, was only a conjecture. But the documents discovered and published by M. Roux-Fazillac in his *Recherches historiques et critiques sur l'Homme au Masque de Fer* (1800), by M. Delort in his *Histoire de l'Homme au Masque de Fer* (1825), and M. Marius Topin, in his *Man with the Iron Mask* (trans. 1869), seemed to leave little doubt on the subject, and the public had apparently made up its mind that the secret was at last discovered, when a still more recent work by a French officer, M. Th. Jung, *La Verité sur le Masque de Fer (Les Enprisonnements) d'après des Documents inédits des Archives de la Guerre et autres dépôts publics, 1664-1703* (1873), conclusively showed that Matthioli could not have been the mysterious prisoner. This Italian adventurer was sent to Pignerol six years after the Mask entered that fortress. He was left behind in Pignerol when Saint-Mars removed the Mask to the Bay of Cannes, and his death there was never kept secret. Matthioli could not speak French; but the *mystery*, the man in the mask, spoke French with a foreign accent, was over the middle height, tall, well made, and fond of music. It says little for the perspicacity of either M. Topin or of his readers that Matthioli should ever have been accepted as the owner of the famous Mask.

M. Jung's hypothesis is vastly more meritorious; in fact, he marshals his facts so dexterously that we should almost say he had succeeded in proving that the Man in the Iron Mask was the unknown head of a widespread and formidable conspiracy, working in secret for the assassination of Louis XIV. and of some of his ablest ministers. The severity of M. Jung's labours with reference to this subject will be understood when it is stated that in the course of his researches he had to examine some seventeen hundred volumes of despatches and reports in the bureau of the Ministry of War. The adventurer upon whom he fastens the Mask was a certain soldier of fortune, a M. de Marchiel, related to several families in Lorraine, and apt to assume their names when an *alias* was required for his purposes. Seized by Louvois's orders at the ford of Peronne, on the morning of March 29, 1673, he was first forwarded to the Bastille. There Louvois saw him, and sent him to Pignerol and to the care of Saint-Mars. From that hour the jailor never parted from his strange prisoner. De Marchiel went with him to Exilles (1687), to St. Marguerite, and died in the Bastille, November 19, 1703. His funeral cost forty livres, and it is entered in the register of the parish of St. Paul as that of 'M. de Marchiely.' His clothes and his Iron Mask were burned, and there the few facts known about this man end. The names and dates all hang so well together that this conjecture is far the most reasonable that has yet been made. But nothing has been proved, except that the Mask was none of the other eleven persons he has been supposed to be. Nothing more will ever be proved until the treasures of the Vatican give up the secret, a secret which the Mask's confessor must certainly have known, and which he *may* have revealed to his ecclesiastical superiors in Rome.

Ironsides, a name popularly applied to the regiment of a thousand horse which Cromwell raised mainly in the eastern counties for service against the king early in the great Civil War. The name, already given for his bravery to an English king, Edmund (q.v.), was first attached to Cromwell himself, but passed easily to the men at whose head he first appeared at Edgehill. Almost from the beginning he saw that real religious enthusiasm was the only force adequate to match the chivalry of the cavalier, and he spent his own money freely on the equipment of his men. 'Old decayed serving-men, and tapsters, and such kind of fellows will never be able to encounter gentlemen,' as he said to Hampden, and the soldiers he gathered round him were stalwart and substantial yeomen, emphatically 'men of religion,' who 'made some conscience of what they did,' who knew the fear of God and no other fear at all. Social distinctions and religious conformity were made subordinate to competence and honesty. 'Better plain men than none; but best to have men patient of wants, faithful and conscientious in their employment,' wrote Cromwell; and elsewhere, 'I have a lovely company; you would respect them did you know them; they are no Anabaptists; they are honest, sober Christians; they expect to be used as men.' And his Ironsides nobly justified their captain's expectations. At Winchby they charged 'singing psalms,' cleared Lincolnshire and the eastern counties of the Cavaliers, endured the shock of Rupert's horse at Marston Moor, and scattered them like chaff before the wind. The whole parliamentary army was next reorganised on the model of Cromwell's brigade, but it was still the stubborn valour of the Ironsides in the left at Naseby that changed the day from defeat to a crushing victory, and practically closed the war. 'Truly they were never beaten,' said Cromwell in a speech the year before his death, 'and whenever they were engaged against the enemy they beat continually.'

Ironton, capital of Lawrence county, Ohio, on the Ohio River, 142 miles above Cincinnati. It is the chief business centre of an important iron region, which gives employment to numerous furnaces, foundries, and other manufactories. Pop. 8857.

Ironwood, a name bestowed in different countries on the timber of different trees, on account of its great hardness and heaviness.—*Actinodendron veru* belongs to the natural order Myrtaceæ, and is a native of Java and other eastern islands. Its wood is much valued by the Chinese and Japanese for making rudders, anchors, &c., and is imported into Britain in small quantities under the name of Ironwood. The bark is used in Japan as a remedy for diarrhoea and mæms discharges. *Mesua ferrea*, a tree of the natural order Guttifera, is a native of the East Indies, and is planted near Buddhist temples for the sake of its fragrant flowers, with which the images of Buddha are decorated. The timber known as Ironwood is very hard, as is that of *M. speciosa*, another tree of the same genus and region. The wood of *Uyris andulata*, of the order Diosmeacæ, is called White Ironwood at the Cape of Good Hope. It is very hard and tough, and is chiefly used for axles, ploughs, and other agricultural implements. The wood of *Olea laurifolia*, a species of olive, is called Black Ironwood in the same country, and is used for the same purposes and for furniture. *O. capensis* is the Ironwood of the Dutch settlers at the Cape of Good Hope, and its wood has similar properties to and is used for the same purposes as the foregoing. *Cappalia subercolan* natural order Sapindaceæ—is the

Ironwood of the islands of Bourbon and Amboyna. The wood is red in colour, very heavy, knotty, and difficult to work; it is used chiefly for making stakes and poles.—*Sideroxylon inornatum*—natural order Sapotaceæ, belonging to the Cape of Good Hope—is named Ironwood and also *Melkhout* by the settlers. The timber is extremely hard, and so heavy that it sinks in water. It is extensively used in boat and bridge building and for agricultural purposes.

Irony (Gr. *αἰρωνία*, *αἰρῖν*, 'a dissembler'), the name applied to a figure which enables the speaker to convey his meaning with greater force by means of a contrast between his thought and his expression, or, to speak more accurately, between the thought which he evidently designs to express and that which his words properly signify. It may be employed to convey assent and approbation as well as the contrary, but it is more properly a weapon belonging to the armoury of controversy, by means of which weight and point may be added to the gravest part of the argument. The dialogues of Plato are admirable examples of a subtle *dialectic* irony, in which the opinion of the adversary is put respectfully in the foreground, and the appearance of deference is never dropped until the supports on which it rests are one by one withdrawn, and the whole is completely undermined and seems to sink by the weight of its own absurdity. Of this rare art in modern literature there is nothing worthy of comparison, save the *Provincial Letters* of Pascal. The *Minute Philosopher* of Bishop Berkeley is one of the most unfortunate attempts at its revival. A more recent master of dialectic irony is the Danish theologian and philosopher, Kierkegaard. The highest triumphs of irony consist not in refutation and demolition, but in clear demonstration of the truth once the fallacy has been exposed and overthrown. Of what may be called practical irony numberless instances of the most various kinds occur in life. A man humours the follies of another to render them more extravagant, either for his own amusement or his victim's ultimate profit; another, under the mask of friendship, panders to the wishes of some deluded man to lead him to his ruin. In such spirit Timon gave his gold to Alcibiades, the witches fed the ambitious hopes of Macbeth, and Mephistopheles echoed the aspirations and the despair of Faust. Fate itself brings bitter irony to bear upon the hopes of mortal life, in the inevitable reflection how little the actual good and ill have corresponded with the antecedent hopes and fears. The calm retrospect of an unembittered age, no longer disturbed by the passions of the actor, is ever tinged with a genial sense of the dumb irony of things as it recognises at last that life has been little more than a vain pursuit of the phantoms of youth. And alike in the broad arena of history we find human impatience and temerity punished by the relentless hand of destiny, as in the signal and sudden reverses that follow close on the heels of arrogant ambition. And so in the microcosm of the drama, which must be a faithful image of human existence concentrated in the mimic sphere. An admirable amplification of this thought as applied to one of the greatest tragedians of all time will be found in Thirlwall's famous essay, 'On the Irony of Sophocles,' in his *Essays, Speeches, and Sermons*, edited by Dean Perowne (1880).

Iroquois, formerly a great confederation of Indian tribes, recognised as a distinct branch of the American family. At the beginning of the 17th century they included the Mohawks, Oneidas, Onondagas, Cayugas, and Senecas, and became known as the 'Five Nations'; in 1715 they were joined by a related tribe, the Tuscaroras, and

henceforward were known as the 'Six Nations.' Each tribe managed its own affairs, under its own sachems, and a council of fifty sachems met annually and disposed of questions affecting the confederation as a whole. The chiefs, who, like the sachems, were of equal rank, but who owed their position to personal valour alone and did not form a hereditary body, exercised leadership in time of war only. The confederation was found by the earliest settlers in possession of the greater part of the present state of New York, but by the end of the 17th century all the tribes between the Atlantic and the Mississippi, and from the St Lawrence to the Tennessee, had been brought under its influence. With the Dutch, and afterwards with the English, the Iroquois always maintained friendly relations, even taking sides with their allies during the Revolution; to the French, on the other hand, they were bitterly hostile, and their enmity had an important effect in checking the growth of French influence in North America. After the Revolution the Mohawks crossed into Canada under Joseph Brant (q.v.), and are now settled on two reservations to the north of Lakes Erie and Ontario. The Cayugas are scattered, and some hundreds only of the Tuscaroras have found a home among the Mohawks; but most of the Oneidas are settled at Green Bay, Wisconsin, most of the Senecas in Western New York, and the Onondagas still hold their beautiful valley near Syracuse, New York. The Iroquois probably never exceeded 25,000, and they still number nearly half as many, most of them in the United States. Schools and missions have met with considerable success, and civilisation is making marked progress among the descendants of this remarkable confederation, while some of their number have attained to distinction as soldiers, engineers, &c.

Irradiation. When a bright object is looked at, an image of it is formed on the retina of the eye. The receiving-apparatus there consists of a number of separate stimulable elements or sets of elements; and for the maximum distinctness of vision no one of these elements should be at all affected by stimulation of its neighbours. If, however, the object be brilliant the image on the retina is very bright, and neighbouring sensitive elements participate in the excitement; a bright object thus looks larger than it is. Examples: bright white letters on a black ground look larger than they are; black letters on a bright white ground look smaller; a white-hot wire appears thickened; the new moon appears larger than the copper-colored 'old moon' which it appears to 'nurse'; and, especially, an electric incandescent lamp often appears, on account of the extreme brilliancy of its attenuated filament, to be almost filled with light.

Irrational Numbers, a term applied to those roots of numbers which cannot be accurately expressed by a finite number of figures. For instance, $\sqrt{2}$ is an irrational number. If the diameter of a circle is one foot the circumference is an irrational number. Irrational numbers have been defined to be numbers which are incommensurable with unity. They are also termed Surds.

Irrawaddy. See **IRAWADI**.

Irregulars, a general term applied to partially-equipped troops engaged in partisan warfare, such as the Franc-tireurs during the Franco-German war of 1870-71. It is also used in connection with the native armies of British India which were re-organised throughout, during the years 1857-61, on what is called the 'Irregular System'—that is to say, with only eight or nine European officers instead of a complete establishment of from twenty-one to

twenty-four. Previous to the Mutiny of 1857 most of the native regiments were on the regular system, the troops or companies being commanded by Europeans, with others under them as subalterns, majors in charge of wings, and a lieutenant-colonel in command, assisted by the usual regimental staff—viz. adjutant, quartermaster, and surgeon. Many of these officers held other appointments, either civil or military, during peace, but rejoined their regiments on the outbreak of war. Only some seven or eight would be found doing regimental duty continuously. A few irregular corps existed having only three European officers, commandant, second in command, and adjutant, attached from the regulars and drawing high rates of pay. The organisation introduced into all native regiments after the Mutiny gives to each cavalry regiment nine European officers from the Indian Staff Corps—viz. the commandant, four squadron commanders, and four squadron officers (one the adjutant). The troop officers are natives, and there is a native adjutant. An infantry battalion has eight European officers—viz. the commandant, two wing commanders, and five wing officers, of whom one is the adjutant and another the quartermaster; the company officers are natives, and there is a native adjutant. The Corps of Guides of the Punjab Frontier Force, consisting of six troops of cavalry and eight companies of infantry, has fourteen European officers. A native battery of mountain-artillery has a commandant and three subalterns, all British, with three native officers under them. The native sappers and miners have a larger establishment of British officers, and also forty European non-commissioned officers. The routine regimental duties are carried on by the native officers, who live in the lines alongside their men, but in separate quarters. The British officers exercise a general system of administration and supervision, and live in cantonments generally at some distance from the lines, except when on service or in camp.

Irrigation (Lat., 'watering'), a method of producing or increasing fertility in soils by an artificial supply of water, or by inundating them at stated periods. Irrigation was probably first resorted to in countries where much of the land must otherwise have remained barren from drought, as in Egypt, where it was extensively practised nearly 2000 years before Christ, and where great systems of canals and artificial lakes were formed for the purpose. Extensive works, intended for the irrigation of large districts, existed in times of remote antiquity in Mesopotamia, Persia, India, China, and some other parts of the East; and in such of these countries as have not entirely lost their ancient prosperity such works still exist. Some plants also require a very abundant supply of water, and irrigation has become general where their cultivation prevails. This is particularly the case with rice, the principal grain of great part of Asia. In Europe irrigation prevails chiefly in the south, where it was extensively practised by the Romans; and it is most extensively practised in northern Italy, and in some parts of Spain and southern France.

Irrigation in Britain, where it was hardly practised till the 19th century, and in most parts of Europe except Italy, is almost exclusively employed for the purpose of increasing the produce of grass by converting the land into water-meadows. The value of it, even for this one purpose, does not seem to be sufficiently understood. Poor heaths have been converted into luxuriant meadows by means of irrigation alone. But in the countries in which irrigation is most extensively practised the production of all crops depends on it.

The irrigation of land with the sewage water of towns is, under another name, the application of liquid manure. In no small degree the water of

rivers and of springs depends on its organic and mineral constituents for its fertilising properties, so that the application of it is not in principle different from that of liquid manure; but it must be borne in mind that the mere abundance of water itself is of great importance for many of the most valuable plants, as the most nutritious substances brought into contact with their roots are of no use to them unless in a state of solution; whilst it is an additional recommendation of irrigation that the supply of water most favourable to the growth of many valuable plants is destructive of some which in many places naturally enumber the soil, as heath, broom, &c. The water which is used for irrigation should be free from mud and such impurities as mechanically clog the pores of leaves, or cover up the *hearts* of plants, and interfere with their growth. Irrigation is far from being so extensively practised in Great Britain as would seem desirable. There are few farms in the British Isles which would not give a handsome return for artificial watering in a dry year—i.e. if the water could be obtained and applied at a reasonable cost. In many instances the produce might be increased two, three, or even fourfold. The amount of moisture which farm crops require to ensure their full development is greater than would be readily conceived. At Rothamsted it was found by Lawes and Gilbert that an acre of wheat in five months and eighteen days evaporated through its leaves no less than 335½ tons of water. Light porous soils benefit most from irrigation; sandy soils, with a little admixture of clay and marl, usually most of all. Except in tropical countries, still retentive clay would not as a rule be benefited by irrigation, and might be injured by it, at any rate for arable farming. Thorough drainage, natural or artificial, is a necessary accompaniment of successful irrigation—necessary so that the soil may not become 'water-logged,' but benefited by the water percolating through it. Soil wholly or partially uncovered by vegetation is liable to be robbed of nitrogen by the rain or irrigation water washing nitrates into the drains or down beyond the reach of the plants. This is avoided in grass land by the roots of the grasses engaging the nitrogen. Irrigation may benefit the land in various ways, most usually (1) by softening and disintegrating the soil in percolating through it; (2) by bringing additional plant food into it; (3) by facilitating the dissolving, preparing, and distribution of the plant food already in the soil; and (4) by the oxidation of any excess of organic matter in the soil, leading thereby to the production of useful carbonic acid and nitrogen compounds. The extent of water-meadows in England is stated to be not more than 100,000 acres. They are mostly confined to the west and south of England. Individual farms, irrigated with sewage water, are to be met with in many parts of England, but the most successful instance of sewage irrigation in Great Britain is to be found near Edinburgh, where an extensive tract of meadows lying between Portobello and Leith yields a rent of £15 to £35 an acre; the grass is cut from three to five times a year, and over ten tons an acre have been obtained at a cutting. See SEWAGE, MANURE.

The methods most generally pursued are what are known as bed work irrigation, catch-work irrigation, and subterraneous irrigation. The first method can be conveniently applied only to ground which is nearly level, and may cost from £20 to £40 per acre. The catch-work method is very much less costly, and can be applied to land whether it is level or not. By the last system the soil is saturated with water from below.

In some parts of the United States irrigation is of vital importance; in 1890 the total area of the

arid lands of the west was 1,331,151 sq. m. In the east the principal use of irrigation is in the rice-fields of South Carolina and Georgia; but such western states as Colorado and Utah are altogether dependent on it, owing to the scarcity of the rainfall. This is true also, to a great extent, of southern California. In all these arid districts hundreds of miles of canals and ditches have been constructed in addition to the mining flumes utilised for irrigation purposes; and as a result wide tracts of desert have been turned into a productive farming country. More recently irrigation has been introduced in western Kansas, largely by canals from the Arkansas River; although here, as in eastern Colorado and California, a great part of the water-supply is obtained from artesian wells. In Arizona, also, it is expected that wide tracts now uninhabitable will be rescued with the aid of irrigation.

In Australia irrigation on an American scale, and according to American methods, has transformed hundreds of thousands of acres, once covered with scrub, into luxuriant vineyards, orchards, and orange-groves, especially in the lower basin of the Murray. The importance of irrigation to the Cape is noticed in the article on that colony; and the irrigation works of India and Ceylon are referred to at INDIA, CEYLON. Egypt (q.v.) is the land most entirely dependent on systematic and careful irrigation.

Irritability in Plants, a term employed to designate phenomena very interesting and curious, but than which none connected with vegetable life are more imperfectly understood. Such are the phenomena of what is usually called the Sleep (q.v.) of plants; the motion of the spores of many cryptogamic plants by means of cilia; the motions of some of the lowest Algae; those caused by agitation or by the touch of a foreign body in the leaves of Sensitive Plants (q.v.); the motions of Insectivorous Plants (q.v.), &c.

Irritation is the term applied to any morbid excitement of the vital actions not amounting to inflammation, and it often but not always leads to that condition.

Irtish, a river of Siberia, the chief affluent of the Obi (q.v.), rises at the east end of the Altai Mountains, passes through Lake Saisan, breaks through the Altai in the west at the bottom of a savage gorge, and flows north-westwards across the steppes of Western Siberia to join the Obi, from the left, at Samarow. At that point it has a width of 2000 yards; its total length is 1620 miles; the area of its basin, 647,000 sq. m. The important towns of Semipalatinsk, Omsk, and Tobolsk stand on its banks. From April to November it is navigable from its mouth as far as Lake Saisan; during the rest of the year traffic is carried on by means of sledges. Its current is gradually shifting eastwards. Its best-known tributaries are the Buchtarma and On from the right, and the Tobol and Ishim from the left.

Iruu, a town in the Spanish province of Guipuzcoa, on the Bidasson, near the French frontier, 24 miles by rail SW. of Bayonne. In 1837 General Sir De Lacy Evans (q.v.) captured it from the Carlists. Pop. 7040.

Irvine, a seaport of Ayrshire, on the river Irvine, $1\frac{1}{2}$ mile from the Firth of Clyde, and 11 miles by rail N. of Ayr, 29 SW. of Glasgow. Made a sub-port of Troon in 1863, its harbour has been improved since 1873; and there are chemical works, foundries, grain-stores, &c. The bridge (1746-1837), the new town-hall (1859), a statue of Lord-justice-general Boyle (1867), and the academy (1814) are features of the town, which became a royal burgh about 1230, and which with Ayr, &c.

returns one member to parliament. It was the birthplace of Galt and James Montgomery, and has memories also of Burns and the Buchanites. Pop. (1841) 4594; (1891) 9086.

Irving, EDWARD, was born in the town of Annan, Dumfriesshire, August 4, 1792, and at thirteen entered the university of Edinburgh. In 1810 he became a schoolmaster at Haddington, in 1812 at Kirkealdy, where three years later he was licensed to preach; and in 1819 he was appointed assistant to Dr Chalmers, then a minister in Glasgow. His sermons did not prove very popular; Chalmers himself was not satisfied. In 1822 Irving accepted a call to the Caledonian Church, Hatton Garden, London. His success as a preacher in the metropolis was such as had never previously been witnessed. After some years, however, the world of fashion got tired of Irving; but it was not till his more striking singularities of opinion were developed that fashion finally deserted him. At the close of 1825 he began to announce his convictions in regard to the second personal advent of the Lord Jesus, in which he had become a firm believer, and which he declared to be near at hand. This was followed up by the translation of a Spanish work, *The Coming of the Messiah in Majesty and Glory*, by Juan Josafat Ben Ezra, which professed to be written by a Christian Jew, but was in reality the composition of a Spanish Jesuit. Irving's introductory preface is regarded as one of his most remarkable literary performances. In 1828 appeared his *Homilies on the Sacraments*. He now began to elaborate his views of the incarnation of Christ, asserting with great emphasis the doctrine of his oneness with us in all the attributes of humanity. The language which he held on this subject drew upon him the accusation of heresy; he was charged with maintaining the sinfulness of Christ's nature. But he paid little heed to the alarm thus created. He was now deep in the study of the prophecies, and when the news came to London in the early part of 1830 of certain extraordinary manifestations of prophetic power in the west of Scotland, Irving was prepared to believe them. Harassed, worn, balled in his most sacred desires for the regeneration of the great Babylon in which he dwelt, branded by the religious public and satirised by the press, the great preacher, who strove above all things to be faithful to what seemed to him the truth of God, gasped at the new wonder with a passionate earnestness. Matters soon came to a crisis. Irving was arraigned before the presbytery of London in 1830 and convicted of heresy, ejected from his new church in Regent's Square in 1832, and finally deposed in 1833 by the presbytery of Annan, which had licensed him. His defence of himself on this last occasion was one of his most splendid and sublime efforts of oratory. The majority of his congregation adhered to him, and gradually a new form of Christianity was developed, commonly known as Irvingism, though Irving had really very little to do with its development (see CATHOLIC AND APOSTOLIC CHURCH). Shortly after his health failed, and, in obedience, as he believed, to the Spirit of God, he went down to Scotland, where he sank a victim to consumption. He died at Glasgow, December 8, 1834, in the forty-second year of his age. See Carlyle's *Miscellaneous Essays* and his *Reminiscences*, and Mrs Oliphant's *Life of Edward Irving* (1862).

Irving, SIR HENRY (born JOHN HENRY BRODRIBB), actor, was born in 1838 at Keinton-Mandeville, Somerset. Educated in London, he was for a time engaged as a clerk in the city, but, having a strong inclination for the stage, made his first appearance at the Sunderland Theatre in 1856. After next

playing at Edinburgh for nearly three years, he first performed in London on September 25, 1859, at the Princess's Theatre. He achieved but a moderate success, though some dramatic readings which he gave at this time at Crosby Hall were warmly commended by the critics. He next played at Glasgow, and then for nearly five years at the Manchester Theatre Royal. After a brief engagement at Liverpool in 1866 he appeared with Miss Kate Terry at Manchester in *Hunted Down*. An invitation to London followed, and he appeared at St James's Theatre with much success as Doricourt in *The Belle's Stratagem*, Dornton in *The Road to Ruin*, and (at the Gaiety) as Mr Chenevix in *Uncle Dick's Darling*. Performances at other London theatres followed, and in 1870, at the Vaudeville Theatre, he made a distinct mark as Digby Grant in Albery's comedy of *The Two Roses*. Migrating to the Lyceum in November 1871, he further added to his reputation by his fine representation of Mathias in *The Bells*. Other impersonations succeeded, including Charles I., Eugene Aram, Richelieu, and Louis XI., until, on the 31st of October 1874, he created genuine interest by his unconventional performance of Hamlet. This Shakespearian masterpiece ran for two hundred nights, and, although the public were divided as to the general merits of the representation, full justice was done to the actor's abilities, and it was universally admitted that Mr Irving had established his reputation as a tragedian of real power and originality. Among other successes under Mrs Bateman's management of the Lyceum were *Macbeth*, *Othello*, *Richard III.*, and *The Lyons Mail*. In December 1878 Mr Irving entered upon his memorable management of the Lyceum Theatre, where his triumphs have been shared by Miss Ellen Terry. He soon added a succession of romantic characters to his repertoire. After performances of *Hamlet*, *Othello*, and *The Merchant of Venice*, which were marked by scenic as well as histrionic excellence, this popular actor appeared in 1880 in *The Corsican Brothers*; in Lord Tennyson's drama of *The Cup* in 1881; in *Romeo and Juliet* and *Much Ado about Nothing* in 1882; *Twelfth Night* in 1884; W. G. Wills's *Olivia* in 1885; *Faust*, adapted by Wills, in 1886; *The Dead Heart* in 1889; *King Lear* in 1892; *Becket* in 1893; *King Arthur* in 1895; *Cymbeline* in 1896, &c. Since 1883 Irving and his company have repeatedly been received with enthusiasm in the United States. He was knighted in 1895, and made D.C.L. of Oxford in 1896. Notwithstanding certain mannerisms of voice, gait, and gesture, he is undoubtedly at the head of contemporary English actors, and he has done much to redeem the stage from formality and mediocrity. See works on Irving by Joseph Hatton (1884), Frederic Daly (1884), William Archer (1885), and Percy Fitzgerald (1893).

Irving, WASHINGTON, was born in the city of New York, April 3, 1783, and died at Tarrytown, New York, November 28, 1859. Copyright 1890 in U.S. His father's family were Scotch, by J. B. Lippincott and claimed descent from William Company de Irwyn, secretary and armour-bearer of Robert Bruce; his mother was English, attached to the Episcopal Church, and of a loving, sunny temper. His education was scanty and desultory. His brothers were sent to college, but he showed no inclination to study, being 'a dreamer and a saunterer.' This arose in part from his tendency to pulmonary disease. He began to read law at the age of nineteen, but after two years, his health being precarious, his brothers sent him to Europe. He landed at Bordeaux in 1804, and went by Marseilles to Italy, escaping with difficulty from Bonaparte's police, who persisted in regarding him as

an English spy. At Rome he was intoxicated by Italian art, and having met Allston, the American painter, was tempted to become an artist, but thought better of it. He visited Paris, the Netherlands, and London, where he saw John Keble and Mrs Siddons. In 1806 he returned to New York in improved health, and was admitted to the bar. Those were 'Corinthian days,' and he led a rather idle life; much in society, and greatly admired.

His first writing was in the *Salmagundi*, a semi-monthly sheet in imitation of the *Spectator*, conducted jointly by himself, his brother William, and J. K. Paulding. It ran for twenty numbers, and then stopped without explanation in the fullness of success. There was considerable merit of a superficial sort in those early attempts, but there was no evidence of a serious literary purpose, for the papers apparently were written with a view only to social distinction. His first characteristic work, and the one by which he will be best known to posterity, was *A History of New York, by Diedrich Knickerbocker*, published in 1809. All readers of English know the little man in knee-breeches and cocked hat as one of the permanent figures in the gallery of literary portraits. The *History* has some grains of truth, but is openly a good-natured burlesque upon the old Dutch settlers of Manhattan Island. The humor and the gravity which mask it are alike irresistible. It may be doubted if there is in the language a more delightful or more perfectly-sustained piece of drollery. Readers of Scott will remember his warm praise of the book, written while 'his sides were sore with laughing.' In the United States it was universally read; and so abiding has been the impression that it is far oftener quoted than any sober historical work. It is to the American people as *real* in its way as the *Pilgrim's Progress*.

For many years after this Irving was in partnership with his brothers in a mercantile business that had relations on both sides of the Atlantic; but in the end they were unsuccessful; and when later he had won his place among authors and was receiving a good income, he supported two of his brothers and five nieces with unselfish devotion. In May 1815 he went to Europe for the second time, and did not return for seventeen years. It was in 1818 that the misfortunes of his firm culminated in bankruptcy, and thereafter he turned his whole attention to literature. He declined liberal offers for magazine work, and would undertake nothing that was to interfere with his plans. The first number of the *Sketch Book* appeared in New York in 1819, and the last in 1820. It was received in the United States with universal delight. Its early success in Great Britain was largely due to the powerful support of Scott. All the pieces in this miscellany have a certain charm—if for nothing more, for their felicitous touch and purity of style. The chief interest, however, centres in 'Rip Van Winkle,' 'The Legend of Sleepy Hollow,' and 'Westminster Abbey.' The last is one of the most finished descriptive essays of our century, though perhaps a little lacking in simplicity. The two legendary tales are in a way related to the *History of New York*, and have had a currency and an influence difficult to measure. 'Rip Van Winkle' is a distinct creation of genius, and with its fellow has made the lower reach of the Hudson classic ground. For the first time there had been produced in the United States a literary work on the highest level of contemporary excellence. *Beauchefield Hall* (1822) fairly maintained but did not raise the author's reputation. It was scarcely necessary, for *Geoffrey Hamlyn, Gent.* was already at the summit of favour. After a few years passed on the Continent he published (1821) *Tabs of a*

Traveller, a work which he thought his best in regard to style, but which some consider to be over-refined.

In 1826 he went to Spain and began the long and arduous studies which were the foundation of his more important serious works. These were *The Life of Columbus* (1828), *Conquest of Granada* (1829), *Voyages of the Companions of Columbus* (1831), *The Alhambra* (1832), *Legends of the Conquest of Spain* (1835), *Mahomet and his Successors* (1850). The last two or three of the works just named were only sketched or partly written before his return to the United States in 1832, but they are given together with the group of which they form part. It was Irving who first revealed to English readers the rich stores of Spanish history and romance; and whatever may be done to correct or enlarge his relations, to him must be given the praise of having produced some of the most fascinating books in existence. He had intended to write the history of the conquest of Mexico, for which he had collected materials, but generously, and to his own loss, relinquished his design to Prescott when he learned that the latter proposed to undertake it. At the end of this sojourn in Spain Irving was for a short time secretary to the United States Legation in London. On his return to his native city (1832) he was received with great enthusiasm. He declined political honours, and continued his literary work. Having made an excursion in the then Far West, he published (1835) *A Tour on the Prairies*. In the same year he published *Recollections of Abbotsford and Weststead Abbey*. He was also at work upon the last of the books in the Spanish series. In writing *Astoria* (1836) he was assisted by his nephew, his future biographer. *The Adventures of Captain Bonneville* (in the Rocky Mountains) appeared in 1837. His biography of Goldsmith was mainly written about this time, though not published until 1849. He remodelled for his own residence an old Dutch house in Tarrytown, near the scene of his legend of Sleepy Hollow. This became well known in after years under the name of Sunnyside. But his intended retirement was postponed by his appointment in 1842 as United States minister to Spain. He returned in 1846 and once more set himself to work. *Goldsmith* and *Mahomet* appeared as already mentioned; then, in 1855, *Wolfert's Roost*, a miscellany. His last work was the *Life of George Washington* (5 vols. 1855-59).

Irving was never married. In his youth he was betrothed to Miss Hoffman, a lovely young lady of eighteen, daughter of the lawyer with whom he pursued his studies. Separated from her by her untimely death, he remained all his life faithful to her memory. In his works there is to be observed a delicacy of feeling towards woman, a chivalrous deference as well as tenderness and affection. He was also exceedingly fond of children and always beloved by them. In his youth he was well made and handsome, and then, as afterwards, was always courted by the best society. Sentiment and abundant humour characterise his writings; but above all, he had the power to seize the attention of cultivated readers by his keen observation, his graphic touches of description, and his limpid and musical style. The early books which first gave him fame, and those which came from his studies in Spain, are the best, for in them his genius is conspicuous. The later productions are respectable, but would not have given him the high rank he deservedly holds. His was a fortunate and honourable life; and, on the whole, though inferior to one or two in genius, he must be pronounced thus far the most successful of the writers of the New World. His *Life* was written by his nephew, Pierre M. Irving (5 vols. 1862-64). There is also

an excellent short biography by Charles Dudley Warner (1881).

Irvingites. See CATHOLIC AND APOSTOLIC CHURCH.

Isaac, one of the Hebrew patriarchs, the son of Abraham and Sarah, and half-brother of Ishmael. His story in Genesis makes him born when both his parents were advanced in age, and die at Hebron at the age of 180, leaving two sons, Jacob and Esau. The Midrash ascribes to him, in allusion to Gen. xxiv. 63, the institution of the afternoon prayer.

Isaac I. COMNENUS, emperor of Constantinople, was the first of the Comneni who attained to that dignity. Under the successors of Basil II. Isaac served in the army, winning the hearts of officers and men by his prudence and uprightness, and on the deposition of Michael VI. in 1057 was elevated to the throne. He established the finances of the empire on a sounder and more stable footing, and, braving the patriarch's threat of excommunication, even laid the clergy under contribution at the tax-collections. He repelled the Hungarians attacking his northern frontier; and then, resigning the crown (1059), retired to a convent, where he lived two years longer. He was one of the most virtuous and able emperors of the East. There are extant from his pen scholia and other works on Homer.

Isaac II. ANGELUS, connected through his mother with the Comnenian emperors, became sovereign of the East in 1185, and reigned ten years. Isaac was a vicious and cowardly prince, and his reign was a period of war and tumult. He was dethroned, blinded, and imprisoned by his brother Alexius in 1195. Eight years later he was restored to the throne, and reigned for a period of six months, when he was again dethroned, and soon after he died in prison.

Isabella of Castile, queen of Spain, born on 23d April 1451, was the daughter of John II., king of Castile and Leon, and in 1469 married Ferdinand V., surnamed 'the Catholic,' king of Aragon. See FERDINAND.

Isabella II. (MARIA ISABEL LUISA), ex-queen of Spain, the elder daughter of Ferdinand VII. See SPAIN.

Isabey. JEAN BAPTISTE, French portrait-painter, was born at Nancy on 11th April 1767, and studied under David. He painted portraits of several of the notabilities of the Revolution, as Saint-Just, Barrère, Collot d'Herbois, and others. Afterwards he became court-painter to Napoleon, and painted him and most of his generals, and important events in his life. After Napoleon's fall Isabey worked for the Bourbon sovereigns. He excelled also as a miniature-painter and as a painter on porcelain. His 'Isabey's Boat' (1796), 'Review of Troops by the First Consul' (1804), 'Members of the Congress of Vienna' (1815), and 'Staircase of the Paris Museum,' a water-colour (1817), are his most important compositions apart from portraits. He died at Paris, 18th April 1855. His son, Eugène (1804-86), was a clever historical painter.

Isæus is, like Wordsworth's cuckoo, 'a voice, a mystery,' for, though we have ten of the fifty speeches he composed, we know absolutely nothing of the facts of his life, except that he pursued the profession of speech-writer in Athens, and that his first speech was composed in 389 B.C. and his last in 353 B.C., so that he may be said to have lived from the time of the Peloponnesian war to that of Philip's supremacy. Isæus did not compose political speeches, or speeches to be delivered in public suits, but exclusively speeches for private suits.

His strength as a lawyer lay in his power of dealing with cases of inheritance, and it is fortunately those of his speeches which deal with this branch of Attic law that have survived to our times. To the student of Aryan institutions and of comparative law, as well as to the student of Attic law, they are invaluable. To the general reader they are less interesting, for the very nature of the cases in which they were delivered—disputes as to *uccum* and *tanu*—forbade any very lofty flights of eloquence. On the other hand, the functions which he discharged in the history of Greek oratory as a branch of literature were of the utmost importance, and explain the fact that he was included in the 'canon' of the ten great Greek orators. It was through Isæus that the change from the older style of Lysias to the new school of which Demosthenes is the greatest representative was effected. He imitated Lysias, and was himself the teacher of Demosthenes. It will be remembered that Demosthenes' first speeches were those delivered by him in his efforts to recover his inheritance, the branch of the law in which Isæus was acknowledged master. The characteristics of the two schools between which Isæus was the connecting link are to be seen in the natural tones of Lysias contrasted with the technical skill of the professional orator which along with higher gifts marks Demosthenes. The importance of this contrast becomes apparent when it is remembered that the speech-writer or logographer was not allowed by Athenian law to speak himself on behalf of his client, but only to compose speeches to be delivered by his client. When speech-writing first became a profession and a branch of literature—i.e. about the beginning of the Peloponnesian war—there was a prejudice in the mind of the average Athenian jurymen against the use of speeches thus written, which made it desirable that the speech should have the appearance of being the speaker's own composition. In adapting his style to the character of his client for the time being Lysias was unrivalled. By the time of Demosthenes the practice of logography was so usual that attempts at disguise were less necessary; and the speech-writer might display all the technical skill of oratory without arousing suspicion. Isæus endeavours to imitate the unprofessional and innocent style of Lysias, but does not succeed in concealing the hoof of the advocate; his simplicity is exaggerated, his sentences have not the careless ease of Lysias, but an ungraceful negligence. At the same time we find in him the germs of that combination of practical utility and artistic beauty which was afterwards to mark the new school. Nor can it be doubted that Isæus surpasses Lysias, as he is himself surpassed by Demosthenes, in pure oratorical skill. Lysias is distinguished for simple colouring but graceful drawing, Isæus for careless drawing but deeper shade, brighter light, and greater wealth of colour. The *editio princeps* is that of Aldus (1513). The best edition and commentary (German) is that of Schömann (1831).

Isaiah (Heb. *Jeshaiab*), son of Amoz, first of the greater Hebrew prophets, was a citizen of Jerusalem, who came forward as prophet about 740 B.C. (probable death-year of King Uzziah), and exercised his office till at least the close of the century. The main object of his prophesying was his people, Israel, sunk in social unrighteousness and idolatry; the subject was his people's God, Jehovah, *called or sovereign in righteousness*, and, because there is nothing higher than righteousness, supreme over the whole world and its forces. From such a God to such people only punishment could pass, and the means for this was present in the great world-power of the day, the Assyrians, four of whose invasions of Palestine Isaiah predicted and lived to see. Be-

cause, however, Jehovah's honour and the existence of true religion upon earth were identified with the continuance of Israel's national history, Isaiah promised the survival of a *remnant*, the stock of an imperial nation in the latter days, and centre for a whole world converted to Jehovah. This *remnant* required a leader and a rallying-place; and it was on these two points that Isaiah's eloquence and hope reached their climax: that a great prince should arise in Judah—though sometimes he described the future without this personage—and that Zion, though closely besieged, should remain inviolate.

In the book of his name, the prophecies generally admitted to be Isaiah's do not lie in chronological order. They may be re-arranged according to the four invasions of Palestine: Tiglath-pileser's, 734-32; Salmanser's and Sargon's, 725-20; Sargon's, 711-10; Sennacherib's, 701. (1) In the prophecies held to be prior to the first invasion (ii.-x. 4; some add x. 5-34, and xvii. 1-14) Isaiah describes his call, arraigns both states of Israel, intimates their invasion, but with a different result for each. To north Israel he holds out no hope: in the worst that can happen to Judah, Zion shall stand, and David's dynasty survive in a prince, whose birth Isaiah predicts as almost immediate, whom he hails as a deliverer from the Assyrians, but his ascriptions to whom are applied by the New Testament and Christian theology to Jesus Christ. Tiglath-pileser retired taking only a small part of north Israel captive. (2) In prophecies of the next invasion (xxviii. and most probably x. 5-xi.) Isaiah repeated the doom of north Israel, and his word was vindicated by the fall of Samaria in 721 and captivity of the people. He warned Judah again, but defied the Assyrian to take Zion, and expanded his prospect of the coming prince and the glory of the nation. Hezekiah, his friend, was now on the throne, and their joint work of abolishing the idols may have begun. (3) About the invasion of 711-10 there is difficulty. Did it comprise Judah? Sayce, Cheyne, &c. say it did, and assign to it Isaiah, x. 5-34, xxvii., and xxxvi. 1, where they read *Sargon* for *Sennacherib*. But of an invasion of Judah by Sargon we have no direct evidence, and hence other critics (Driver, Robertson Smith, &c.) assign to this period only xx., xvi. 1-10, perhaps xvi. 13-14 (the rest of xv.-xvi. being earlier), and the events in xxxviii. and xxxix. (4) With 705—the revolt of Sargon's vassals against Sennacherib, his successor, and Sennacherib's preparations to reduce them—we reach the most fertile period of Isaiah's prophesying. In xxix.-xxxii. he denounces Jewish intrigues with Egypt, predicts the siege and deliverance of Zion, and promises to faith and sincerity a glorious future. In another set of oracles to foreign nations, not all dating from this time, xiv. 24-32, perhaps xvii. 12-14, xviii., xix., xxi., xxiii., he intimates to a number of tribes the futility of their resistance to Assyria, and affirms that only Zion shall stand. In 701 Sennacherib overran Judah, and seems to have been bought off by Hezekiah, only, however, to send back a corps under the Rab-shakeh to demand Zion's surrender. It was this corps whose sudden withdrawal, upon news of a great disaster to the main army at Pelusium, set Jerusalem free, and so gloriously vindicated Isaiah's word. His orations during these events are probably chap. i., describing the devastation of Judah; xvii., the panic and profligacy of the capital on the first appearance of the enemy; and xxxiii., the prophet's final triumph at the Assyrian withdrawal; with the detailed narrative of events, xxxvi. 2-xxxvii. After this triumph in 701 it is very uncertain that we have anything more from Isaiah, except it be the latter half of xix., which has been

called his 'swan-song.' Of his end we know nothing: a tradition exists that he was slain to death in the persecution of Manasseh (cf. Epistle to Hebrews, xi. 37; Genara, Jehamoth, 49 *b*, and Sanh. 103 *b*; Joseph, *Antiq.* x. 31).

There still remains a large portion of the Book of Isaiah, xiii.-xiv. 23, xxiv. xxvii., xxxiv., xxxv., and xl.-lxvi. The first doubts as to the authenticity of these were started by Aben-Ezra, and followed up by Koppe (1779), who suspected that xl.-lxvi. were of later date, and after him by an increasing, and now the main, body of critics on the Continent and in Britain—Gesenius, Hitzig, Knobel, Umbreit, Ewald, A. B. Davidson, Cheyne, Driver, Robertson Smith, Kuonen, Wellhausen, &c.; and to a less degree, Delitzsch, Bredenkamp, Orelli, &c. No critic of any eminence now claims all sixty chapters for Isaiah; and indeed the belief that they were all his could only have originated through the taking for granted that the title of chap. i. covers the whole book—an opinion falsified by the appearance of titles for some of the following chapters and their absence from others. None of the chapters in question, save xiii., claim to be Isaiah's, and that they are not his may be argued, apart from the uncertain and confusing testimony of style, vocabulary, &c., upon grounds of historical evidence. The circumstance and horizon of these prophecies are entirely different from those of the authentic oracles. Assyria is no more the dominant world-power, nor Zion the inviolate fortress of God. The Jews are not in their own land: they are either in exile or just returned. It is no more the repulse of the invader or the recovery of Zion from siege that is predicted; but the overthrow of the tyrant in his own land, the redemption of a captive people, the laying down of a highway for the return of exiles, the rebuilding of the city, and the resumption of worship. Exile is not foretold, nor the effort made to lift the imagination to it as certain. It is described as present: the people are addressed as in exile, their conscience is appealed to as the conscience of a people who have suffered and acknowledge their penalty. In the case of xl.-lxvi. there is an additional argument. In some of these chapters Cyrus, who appeared about 550 or more than a century after Isaiah's death, is not only named as the deliverer of the exiles, and described as existing in the flesh; but in a debate (chap. xli. ff.) about Jehovah's righteousness—i.e. his fidelity to his ancient promises of deliverance and his ability to perform them—Cyrus is presented both to Jew and heathen as a living proof that these promises are about to be fulfilled—which surely would have been an utterly vain proceeding, if Cyrus were not already there, visible to all men. This very definite evidence overbears not only the resemblances in style between xl. lxvi. and Isaiah's own oracles, but also such facts as that Isaiah foresaw the Babylonian captivity (xxxix.) or that he once wrote from the standpoint of a much larger exile than happened in his own day (xi.). It is quite possible, though incapable of proof, that the disputed prophecies contain fragments from Isaiah himself. That they contain at least pre-exilic fragments is more certain: lvi. 9 lvii. 11 implies that the Jewish state still exists, and bears traces of an origin in Palestine. By some lviii. ff., especially lxiii. lxvi., are held to be post-exilic. Originally in the Jewish canon the Book of Isaiah seems to have followed Ezekiel, a fact which seems to confirm the late date of at least parts of the book.

See Commentaries by Alexander (1817; new ed. 1875), Ewald, Delitzsch (trans. 1891), Orelli (trans. 1891), and the present writer (in 'Expositor's Bible,' 1891); Driver's *Isaiah: his Life and Times* (1888); Kennedy's *Unity of Isaiah* (1891); works by Cheyne (1870-95); and Matthew Arnold's two books on Isaiah.

Isambert, FRANÇOIS ANDRÉ, French lawyer, was born at Annay (Eure-et-Loire) on 30th November 1792. In 1818 he began to practise as an advocate at the Court of Cassation in Paris. Here he soon made a name as a political advocate, ranging himself in opposition to the Restoration government. About this time he greatly enhanced his reputation by publishing *Recueil Général des Anciennes Lois Françaises* (29 vols. 1821-33), *Traité du Droit Public et du Droit des Gens* (5 vols. 1823), and *Code Electoral et Municipal* (2d ed. 1831). He also interested himself actively in the condition of the liberated slaves in the French West Indian colonies. After the July revolution of 1830 he was elected councillor of the Court of Cassation and elected a member of the Chamber of Deputies. From this year down to 1848 Isambert belonged to the Constitutional opposition, signalling himself as a friend of liberty and an opponent of the Jesuits. The chief literary productions of the later part of his life are *Etat Religieux de la France et de l'Europe* (1843-44) and *Histoire de Justinien* (1856). His *Pandectes Françaises*, a collection of French laws, edicts, and ordinances, from 1789 onwards, was left unfinished. Isambert died at Paris on 13th April 1857.

Isandula, or ISANDHLWANA, in the north-east of Natal, on the left bank of the Buffalo River, 110 miles N. by W. of Durban. There, on 22d January 1879, the British camp, comprising four companies of the 24th, with a native contingent, under Colonels Durnford and Pulleine, was surprised by 18,000 Zulus in Lord Chelmsford's absence and almost annihilated. The British loss exceeded 800, that of the Zulus 2000.

Isar, or ISER, a river of Bavaria, rises in the Tyrol, north-east of Innsbruck, and flows 220 miles, generally in a north and north-east direction, till it falls into the Danube near Deggendorf. Munich and Landshut are on the banks of Isar, rolling rapidly; Hohenlinden (q.v.) is 20 miles away. In the first part of its course it is an impetuous mountain-torrent; and even after it leaves the Alps it has many rapids and islands. Large quantities of wood are floated down the Isar from the mountains. Area of its drainage basin, 3545 sq. m.

Isauria, in ancient geography, a district of Asia Minor, occupying the summit and northern slopes of Mount Taurus. The people were stern and savage, like their native mountains, and occupied themselves principally in robbery and piracy. At length their depredations and those of their neighbours, the Cilicians, became so formidable that the Roman proconsul, P. Servilius, chased them into their mountain fastnesses and coerced them into submission in 76 B.C., for which exploit he acquired the surname Isauricus. Nevertheless the Isaurians were not subdued. Pompey, in warring against the Mediterranean pirates, drove them off the sea; but they soon returned again. Indeed so far was their power from having been broken that they conquered the Cilicians, and remained the terror of the neighbouring states down to the 4th century. In the reign of the Emperor Gallienus (253-268) there even arose among this savage folk a rival emperor, Trebellianus, who, however, was finally crushed. This same people also gave two emperors to Byzantium, Zeno I. (474-491) and Leo III. (718-741); the descendants of the latter ruled over the empire of the East for three generations. From the 5th century onwards the Isaurians gradually disappear from history.

Ischia (the ancient *Enuria* and *Pitheusa*), an island on the north side of the entrance to the Bay of Naples, 6 miles from the mainland. Area, 26 sq. m.; pop. (1881) 22,170. Ischia is a favourite

place of summer resort, being noted for the excellence of its warm mineral waters, the great richness of its soil, the exquisite flavour of its fruits and wines, and the enchanting character of its scenery. Its highest point is the volcanic Monte Epomeo, 2608 feet, the last outbreak of which occurred in 1302. In 1881 Casamicciola was nearly destroyed by two earthquake shocks. A still more dreadful catastrophe befell it on September 28, 1883, when the town was utterly overwhelmed, only four or five buildings being left standing, and four or five thousand persons lost their lives. The inhabitants grow fruits, wine, and olive-oil, and carry on fishing. Chief towns: Ischia (2741), a bishop's seat; Casamicciola (3063); and Torio (3157). See Johnston-Lavis, *The Earthquakes of Ischia* (Naples, 1886).

Ischl, a town of Upper Austria, surrounded on all sides by gardens, is finely situated, 1536 feet above sea-level, on the river Traun, amid magnificent Alpine scenery, 33 miles E. by S. of Salzburg. It is the chief town of the district called the Salzkammergut (q.v.). The situation of Ischl, and the saline baths, established in 1822, attract 4000 or 5000 visitors annually, including the Austrian royal family, who have built a villa. About 8000 tons of salt are manufactured here every year in the salt-works, opened in 1571. Pop. 2124. See *Ischl und seine Umgehung* (7th ed. 1885).

Isghem, a town of Belgium, 10 miles by rail N. by W. of Courtrai, has linen and lace manufactures, and a pop. of 9520.

Iseo, LAKE (*Lacus Sabinus*), a lake of Northern Italy, situated between the provinces of Bergamo and Brescia. Length, 12½ miles; maximum breadth, 3½ miles; area, 24 sq. m. It contains two small islands, and is fed by the Oglio, a tributary of the Po.

Isère, a department in the south-east of France, round which on the north and west flows the river Rhone. It was formed out of the ancient province of Dauphiné. Area, 3200 sq. m.; pop. (1872) 575,784; (1886) 581,680; (1891) 572,145. The surface is level in the north-west, but becomes mountainous and picturesque in the east and south-east. Mont du Midi, on the south-eastern border, rises to 13,088 feet. The chief river, besides the Rhone, is its left-hand tributary, the Isère, which, rising in the Alps at an altitude of 7540 feet, flows south-westwards to join the Rhone above Valence, after a total course of 180 miles (102 navigable). The products include wheat, wine, stone fruits, medicinal plants, and hemp. Cheese is made; and silkworms are reared. The department is rich in mineral products; iron, coal, and turf are worked, and to a less extent marble, slates, and gypsum. The industrial activity is considerable, particularly in the manufacture of iron and steel goods, gloves, silk stuffs, cloth, linen, paper, straw-hats, liqueur (Chartreuse), &c. The department contains four arrondissements, Grenoble, La Tour-du-Pin, St Marcellin, and Vienne; capital, Grenoble.

Iserlohn, a manufacturing town of Prussian Westphalia, is situated on a tributary of the Ruhr, 14 miles S.E. of Dortmund. The industry is chiefly directed to the manufacture of hardware, especially of brass and bronze articles. The calamine mines are celebrated. In the neighbourhood is the Deelen stalactite cave, 292 yards long, discovered in 1868. Pop. (1875) 16,868; (1895) 24,722.

Isernia (anc. *Esernia*), a town of Italy, in the Apennines, 52 miles N. of Naples. It is surrounded by walls, built on the cyclopean Samnite remains. Among other antiquities is a subterranean aqueduct. The town, much injured in 1805 by an earthquake, is the seat of a bishop. Pop. 7678.

Ishmael, the son of Abraham, by Hagar, the Egyptian handmaid of his wife Sarah. In the story of his life given in Genesis he was driven at fifteen from his father's house along with his mother, and grew up to manhood in the southern wilderness a famous archer. He became the progenitor of a great nation, and the character of the Arabs was supposed to have been foretold in Gen. xvi. 12. Mohammed asserted his descent from Ishmael, and the Mohammedan doctors declare that Ishmael, and not Isaac, was offered up in sacrifice—transferring the scene of this act from Moriah in Palestine to Mount Arafat near Mecca.

Ishpeming, a city of Michigan, 15 miles W. of Marquette on Lake Superior, and 392 miles N. of Chicago by rail. Large quantities of iron ore (a red hematite) are quarried close by, and the town possesses foundries, blast-furnaces, &c. Many of the miners are Scandinavians. Pop. 6840.

Isidore of Seville (ISIDORIUS HISPALENSIS), one of the most distinguished ecclesiastics at the beginning of the 7th century. He was born most probably about 560, either at Seville or at Carthagera, where his father, Severianus, was prefect, and he succeeded Leander as Archbishop of Seville in the year 600. Two of his brothers, Fulgentius and Leander, were, like himself, bishops, the first of Carthagera, the second Isidore's successor in the see of Seville. The episcopate of Isidore is rendered notable by the two half-ecclesiastical, half-civil councils at Seville in 618 or 619, and at Toledo in 633, which were held under his presidency, and the canons of which may almost be said to have formed the basis of the constitutional law of the Spanish kingdoms, both for church and for state, down to the great constitutional changes of the 15th century. He also collected with the same object all the decrees of councils and other church laws anterior to his time. His death, which occurred in 636, forms one of the most remarkable scenes in early Christian history. When he became sensible of the approach of death he summoned his flock to his bedside, exhorted them to mutual forbearance and charity, prayed their forgiveness for all his own shortcomings in his duty, and directed all his property to be distributed among the poor. At the eighth Council of Toledo in 653, the epithet *Egyptius* was applied to him, and later Pope Benedict XIV. permitted the office of St Isidore to be recited in the universal church with the antiphon 'O doctor optime,' and the gospel 'Vos estis sal terra.'

Isidore was a voluminous and learned writer in a Latin ornate rather than pure, and his personal character stands high for its simplicity and goodness. His writings include *Etymologies* or *Origines* treating of the whole cycle of the sciences, and showing wide reading in the Greek and Latin classics; *Libri Differentiarum sive de propriitate sermonum*; *Præsentia in Libros Vet. et Nov. Test.*; *Questiones tunc de Nov. quam de Vet. Test.*; *De Fide Catholica contra Judæos*; *Sententiarum Libri iii.*; *De Ecclesiasticis officiis*; *Synonyma de laudatione animæ peccatricis*; *Regula Monachorum*; *De Natura Rerum Liber*; *Chronicon*; *Historia de regibus Gothorum, Wandalorum, et Suevozum*; and *De Viris Illustribus Liber*.

The standard edition is that of Arevalo (7 vols. 4to, Rome, 1797-1803), reprinted by the Abbé Migne in his *Patrologia Latina* (lxxxi, lxxxiv, l), together with the *Collectio Canonum* ascribed to Isidore. Vols. lxxxv, lxxxvi, of the latter also contain the *Liturgia Mozarabica secundum Regnum Bæti Isidori*.

Isidorian Decretals. See CANON LAW.

Isinglass (supposed to be derived from the German *Hausablase*, 'bladder of the sturgeon'), the *Ichthyopoda* (*ichthys*, 'a fish'; *lolla*, 'glue') of the classical and scientific writers, was formerly obtained only from the common sturgeon (*Acipenser sturio*), and consisted of the dried air bladder of

the animal. The necessities of modern commerce have, however, led to the discovery that the same part in many other fishes forms good isinglass; and instead of Russia, as formerly, being almost the only producing country, large quantities are now brought to Britain from South America (chiefly from Maranhão), some from the East Indies, New York, and Canada. The commercial varieties of this material are numerous; and besides them others are occasionally met with, as the *Mauilla*, in thin cakes; the *Para*, which is the most remarkable of all, resembling grapes of a reddish-brown colour, growing from a straight thick stem, being the dried ova of the *Sudis gigas*, a large fish common in the mouths of the Amazon. An inferior kind is also made of cod-sounds and sole-skins, sufficiently good, however, to be used in fining beer and other liquids. Isinglass, strictly speaking, is not Gelatine (q.v.), but a good gelatine-yielding tissue, its value being enhanced by the ease with which it is abstracted from the membrane when compared with the complicated process necessary for separating and purifying the gelatine from the skins, &c. of other animals. When separated, however, the substances are identical in composition, and, if pure, are undistinguishable from each other.

ISIS, the name applied by Leland, Camden, &c., and in the form *Ysa* by Higden (14th century), to the upper part of the river Thames (q.v.). For a long discussion of the origin of the name—a classicised form perhaps of the Celtic *uisgr*, 'water'—see *Notes and Queries* for 1882-84.

ISIS, an Egyptian goddess. The deities of ancient Egypt might be male or female, but in neither case could the Egyptian worshipper conceive a deity as existing in isolation; to every deity of either sex there must be a counterpart of the other sex. It was to this notion that the goddess Isis owed her origin; she was the counterpart of Osiris, and this fact is expressed in the statement that she was at once wife and sister of Osiris. But in all such cases the counterpart remained a much less important personage than the original deity, whether male or female. The mythological functions of Isis accordingly will be found to be subordinated, at any rate in their oldest forms, to the myth of Osiris. In the next place, as the child is the reproduction of its parents, for the father lives again in his children, the son was to the Egyptian in a way identical with the father, and when, as in the case of the gods, the mother was but the counterpart of the father, the identity of the child with the parents was yet more complete. In other words, as a child is impossible without parents, so it is impossible for a father to exist without a child of which he is the father. Hence we find that the deities of ancient Egypt are grouped in triads or triunities. Father, mother, and child cannot be conceived except in relation to each other (the terms are correlative); yet, though identical and inseparable, they are nevertheless distinct. The deity who completed the triad in the case of Osiris and Isis was their son Horus. In order to understand the position occupied by this triad in the circle of ancient Egyptian deities it is necessary to premise that Egypt was no exception to the laws which govern the growth of all political communities. All states which are larger than mere city states have become larger by the amalgamation or *synoikismos* of smaller unities. The smaller states out of which Egypt as a political whole was formed still continued after the political unification of the country by Menes to exist as administrative districts, even when Egypt became part of the Roman empire, just as the boundaries of a modern English county in many cases represent the frontiers of ancient states.

In Egypt these divisions are generally known under their Greek name as 'nomes.' Each nome, while yet an independent state, possessed its own local deities. When, however, they were brought under one government a pantheon was necessarily formed, and the order of precedence amongst the various local deities arranged. Practically, however, each nome continued to regard its own deity or trinity as really the supreme god, unless it could succeed in identifying its own deity with some other member of the national hierarchy. This explains on the one hand the statement of Herodotus (ii. 42) that no gods were worshipped universally in Egypt except Osiris and Isis, and on the other hand it enables us to understand how it comes about that Isis was worshipped as Mut at Thebes, as Sekhet at Bubastis, and as Hathor or Athor at Dendera, as Sothis, the dog-star, and as the planet Venus. It also explains why Osiris, originally the local deity of Abydos, came to be universally worshipped throughout Egypt. Osiris undoubtedly owed his elevation in the Egyptian pantheon to the fact that he was identified with Ra, the sun or sun-god. In chapter 17 of the *Book of the Dead* this identification is expressed in the explicit terms, 'Ra, the soul of Osiris, and Osiris, the soul of Ra.'

We may now proceed to the mythological functions of Isis. As being the counterpart, the sister of Osiris, she was the child of the same parents as her brother and husband—of Seb (or, as some transliterate it, Qeb), the earth, and Nut, the sky. The beneficent course of the sun across the sky is terminated by his murder at the hands of his brother Set. But though the sun dies to-night, to-morrow there lives another sun, who is different and yet the same, as the child is different from and yet the same as his father. This is Horus, who avenges the death of his father Osiris. Within the limits of this myth place was found for Isis as the faithful wife of Osiris, who recovered the body of her murdered husband, after it had been flung into the Nile by Set. Having concealed the body, Isis fled to her son Horus, and during her absence Set found the body and cut it into fourteen pieces, which he scattered. These Isis collected and buried in a stately tomb. The question at once presents itself, what was the original meaning of the mythological functions ascribed to Isis in the myth of Osiris? And we may conjecture that the answer is to be sought in the original local character of Egyptian deities, in the process of identification, or 'syncretism,' and in the ritual which grew out of it. Horus was originally the local god of Edfu; he may have been a solar deity, at anyrate he came to be regarded as the same, yet not the same, as the local solar deity of Abydos, Osiris. He was interpreted as the son of Osiris. But Horus was in conflict with Set; obviously, therefore, it must have been as the avenger of his father, Osiris, that Horus engaged in conflict with Set, though before Horus was brought into connection with Osiris no such story existed. Again, Horus, before he was identified as the son of Osiris, had a mother of his own, Hathor, the local deity of Dendera. By what process Horus, the god of Edfu, had come to be regarded as connected with the goddess of Dendera we do not know. But the connection was expressed in ritual by a religious procession from Dendera to Edfu. Accordingly, when Horus became the son of Osiris, and Athor in consequence was identified with Isis, the procession in which the image of Athor—i.e. Isis—visited Horus at Edfu required a mythological explanation. It was provided by the invention of the myth of Isis' flight to Horus after the death of Osiris. The dismemberment of Osiris and the collection of the members by Isis is apparently an invention to account for the phallic ceremonies, which survive to the present day in

Egypt. From this analysis of the myth of Isis and Osiris, it becomes apparent that the deities of ancient Egypt were not originally conceived in triads; but that, on the contrary, the trinity of the god was a later doctrine designed to explain the syncretism which resulted from the amalgamation of the various nomes and their deities. There is yet another mythological function ascribed to Isis which requires mention and explanation: she rocks the cradle of the infant Nile. To the Egyptian the conflict between the sun and the powers of darkness, in the heaven above, may have had its parallel on the earth beneath in the perennial conflict between the beneficent Nile with the sands of the desert. At anyrate, Osiris had the Nile as well as the sun for his emblem; and by a not unnatural confusion between Osiris and Horus, for Horus is Osiris in his youth, Isis was regarded as tending the infant Nile. Finally, we may dismiss Isis in Egypt by adding that she as Neith was regarded as the patron goddess of women, and presided over child-birth.

But we have yet to trace the fortunes of Isis in Greece and in Rome. As early as Herodotus (ii. 156) she was taken to be the same as the Greek Demeter—for no other reason apparently than that Demeter, like Isis, suffered a great loss. Only, it was her daughter, not her husband, that Demeter lost. This was, however, a trifle to stand in the way of a Greek resolved to identify his mythology with that of the oldest, the wisest, and most religious of mankind. After the time of Herodotus—probably, indeed, not until post-classical Greek times—on the ground that the wife of the sun must be the moon, Isis became a moon-goddess, and was identified by the Greeks with their moon-goddess Io. Again, as Athor, Isis was imagined to be the same as the Semitic Astarte and the Greek Aphrodite. When the attributes and powers of all these goddesses were ascribed by the (post-classical) Greeks to Isis it is easy to understand that in the Orphic mysteries Isis was the chief and most mysterious of all goddesses. Nor have we any difficulty in recognising that the Pans and Satyrs and the nursing of Astarte's children, &c. which appear in Greek accounts of Isis are borrowed from myths that really belong to Demeter, and are not Egyptian at all. Our two chief Greek authorities, Diodorus Siculus and Plutarch (*De Isid. et Osir.*), draw mainly upon one Hecateus, of the time of Alexander; and we may say generally that it is impossible to trace Isis as a figure in Greek mythology farther back than the age of Alexander.

It is in the Roman empire that Isis becomes a mythological figure of importance outside Egypt. The process of syncretism was carried further in her case than in that of any other deity. Every function ever attributed to any deity whatever was transferred to her, and the result is best stated in the words of the mysterious goddess herself to the Golden Ass of Apuleius (*Met.* xi. 241): 'I am the universal mother nature, mistress of all elements, first-born of the ages, supreme of goddesses, queen of names, ruler of the gods, sole manifestation of all gods and goddesses, whose glance makes awful silence in the shining heights of heaven, in the depths of the sea, and of the world beneath, whose unchanging being is worshipped under many forms, with many rites, and under various names, as mother of the gods, as the Cerepian Minerva, Paphian Venus, Dietynnian Diana, Stygian Proserpina, the ancient goddess Ceres, as Juno, Bellona, Hecate, Rhamnusia—but my true name is Queen Isis.' To this we may add the inscription mentioned by Proclus: 'I am that which is, has been, and shall be. My veil no one has lifted. The fruit I bore was the Sun.'

Iskanderoon. See SCANDEROON.

Isla. JOSÉ FRANCISCO DE, was born in 1703 at Vidanes, in north-western Spain. Early in life he joined the Jesuits, for some years was lecturer in philosophy and theology at Segovia, Santiago, and Pamplona, and became famous as a preacher, but still more as a humorist and satirist by his writings, especially his novel of *Friar Gerund*. Except Cervantes and Quevedo no man had a larger share of that peculiar grave humour which is one of the special products of Spain, and with him it seems to have been almost irrepresible. Even in *Youth Triumphant*, an account of a masque performed by the students of his own order at Salamanca in 1727, in honour of the canonisation of two young Jesuits, he could not altogether control his propensity to ridicule. The *Letters of Juan de la Encina*, written in 1732, on a pamphlet by a quack doctor at Segovia who had given him offence, are a good example of his style, but a more characteristic one is the *Dia Grande de Navarra*, a description of the ceremonial at Pamplona on the accession of Ferdinand VI. in 1746, which he wrote at the request of the local authorities. It is, in fact, an adroit caricature of the grandiloquence, pomposity, and inflated phrase usual on such occasions, but his artful flattery of provincial vanity and official self-importance blinded the eyes of the good Pamplonese, and they passed a vote of thanks to him, which he appealed to with an admirable assumption of injured innocence when the wits of Madrid charged him with the joke. He had a hearty contempt for shams and pretences of all sorts. *Friar Gerund* was aimed at the charlatanism of the popular preachers of the day, especially the preaching friars. The decline of culture produced uncritical audiences, and these again swarms of preachers who tried to get credit with the crowd for originality by tricks, mannerisms, and clap-trap. Isla's model, as he owned in his preface, was *Don Quixote*; what Cervantes had done with the sham chivalry and sentiment of the romances, he strove to do with the vulgar buffooneries of the pulpit, and he was almost equally successful. The first volume came out at Madrid in 1758, and in three days the whole edition of 1500 was sold off. From the king down everybody was delighted with it—everybody, that is, except the friars, for 'Fray Gerundio' at once became a nickname, and their congregations, they found, laughed at instead of with them. But the friars were a power, and at their instance the Inquisition stopped the publication of the book. A clandestine edition of vol. ii., with the imprint of Campazas, as well as a reprint of vol. i., came out in 1770, and another in 1787, but none with a license until 1813. Isla was struck down with paralysis in 1767 as he was obeying the edict expelling the Jesuits, but he insisted on sharing the lot of his comrades, and betook himself to Bologna, where he lived, cheerful and uncomplaining, in poverty and ill-health, until the end of 1781. A little before his death he wrote his translation of *Gil Blas*. A friend had urged him to assert their country's claim to a book that, as the French themselves acknowledged, had been stolen from Spain, but he objected that he was not David enough to attack such a Goliath as Le Sage, and that he had never read *Gil Blas*. But afterwards, having nothing to do, he took it up and translated it, and further amused himself with a preface in which he humoured his friend's patriotic idea in his own grave way, by a circumstantial story in the style of *Gerundio* and the *Dia Grande*, of how Le Sage

(who never was in Spain), being in the suite of the French ambassador at Madrid, met a certain Andalusian advocate who gave him the MS. of the novel. On his title-page he put, 'Stolen from Spain, and restored to its country and native language by a jealous Spaniard who will not allow his nation to be made game of;' words which sufficiently indicate his drift; but his gravity imposed upon the Comte de Neuchâteau of the French Academy, and provoked a serious refutation in 1818, to which Llorente replied in 1820; and the controversy, having that element of paradox which gives vitality to argument, still maintains a fitful existence. See LE SAGE.

The best edition of Isla's works is that in vol. xv. of the *Biblioteca de Autores Españoles*, giving *Fray Gerardo*, the *Cartas de Juan de la Encina*, the *Día Grande de Xacurca*, and a full collection of his delightful letters, but omitting his sermons and translations. The English translation of *Fray Gerardo* (1772), by Dr Warner (some say Dr Nugent), is somewhat abridged and a little vulgar in its attempts at the dialect of the Campos rustics, but on the whole pretty faithful.

Isla de Pinos. See PINOS, ISLA DE.

Islām. or ESIĀM (Arab.), the proper name of the Mohammedan religion; designating complete and entire submission of body and soul to God, his will and his service, as well as to all those articles of faith, commands, and ordinances revealed to and ordained by Mohammed the prophet. See MOHAMMEDANISM.

Islamabad. See CHITTAGONG.

Island (A.S. *igland*, *ig*, 'island,' and *land*. *Ig* is cognate with Icel. *ey*, Dan. *ø*, and ultimately with A.S. *ea*, Gothic *ahva*, and Lat. *agua*, all signifying 'a stream,' 'water.' The *s* in island crept in through confusion with Fr. *isle*, derived from Lat. *insula*, land surrounded by water. The larger masses of land surrounded by water, or parts of them, are Continents (q.v.), and the term island is usually restricted to the smaller. Since Australia has an area of over 3,000,000 sq. m., and (omitting Greenland, which is possibly an ice-bound archipelago) New Guinea, the next island in size, has only 303,000 sq. m., the distinction drawn between continents and islands in the restricted sense is more than verbal. There are few large islands. Borneo, indeed, is little inferior in size to New Guinea; but Madagascar and Sumatra are the only others with an area greater than 100,000 sq. m. Honshū (the main island of Japan) and Great Britain rank next, the latter being sixth in order of size if New Guinea is taken as first. The following table shows the relative mainland area of the largest islands.

Islands.	Area in sq. m.	I-lands.	Area in sq. m.
New Guinea	303,000	Iceland	39,800
Borneo	284,000	Mindanao	37,000
Madagascar	227,000	Ireland	32,000
Sumatra	165,000	Haiti	28,800
Honshū	186,500	Tasmania	26,200
Great Britain	83,700	Ceylon	24,700
Celebes	68,800	Nova Zembla (N. Island)	19,300
New Zealand (S. Island)	58,500	Tierra del Fuego	18,500
Java	48,400	Nova Zembla (S. Island)	15,700
Cuba	45,000	Formosa	15,000
New Zealand (N. Island)	44,500	Hainan	14,000
Newfoundland	41,200	Sicily	9,300
Luzon	40,900	Sardinia	9,200

Two classes of islands may be distinguished—continental and oceanic. *Continental Islands* are closely allied by the structure of their rocks to the nearest continental land, from which they are rarely far distant, although sometimes—as in the case of Madagascar and New Zealand—separated by depths exceeding 1000 fathoms. As a rule, continental islands lie to the south and east of the continent with which they are associated. The only exceptions to this rule are islands on

the continental shelf—i.e. separated by depths less than 100 fathoms, which have been cut off from the mainland in geologically recent times. With the exception of Madagascar and New Zealand, the separation of which is unusually complete, the plants and animals of continental islands are similar to those on the adjacent continent, and from the slight differences detected the period at which separation took place has sometimes been calculated. Groups of continental islands enclosing seas stretch from the south-east peninsula of each of the northern continents towards the nearest southern continent. The Greek Archipelago points from the Balkan Peninsula towards Africa, the West Indies run from Florida and Yucatan to South America, and the Eastern Archipelago extends from the Malay Peninsula to Australia. These archipelagoes represent mountainous tracts of continent which have subsided, or else irregular portions of the submarine plateaus which are undergoing elevation. Professor James Geikie points out in a paper (*Scot. Geog. Mag.*, February 1890) that in past geological epochs groups of great islands occupied the sites of the present continents, and he shows reason for believing that the evolution of continents by the incorporation of islands on the great world ridges is still going on, although accompanied by the formation of new islands through local erosive action on the coasts.

Oceanic Islands rise abruptly from great depths, and show no geological continuity with the continents. They appear above the surface either as (a) *Volcanic Islands*, usually rugged peaks or vast accumulations of lava nearly as precipitous below the surface as above, or as (b) *Coral Islands* (q.v.). Numerous submarine mountains have been discovered in different parts of the ocean, which only require moderate elevation or the deposition of sediment or coral growth to appear on the surface as islands. The fauna and flora of oceanic islands like those of Madagascar and New Zealand, which biologically resemble oceanic islands, differ widely from those of the continents, and present many features of unique interest, which have been worked out in detail by Wallace in his *Island Life*. See GEOGRAPHICAL DISTRIBUTION.

Continental islands have in historical times formed the cradles of great commercial nations, the insular position giving security, and the water border acting at once as a barrier to the less adventurous continental people and as a highway to the bolder islanders, whose closer contact with the sea makes them nations of sailors.—For Floating Islands, see that head; and for the 'Islands of the Blessed' and other fabulous islands, see ANTILLES, ATLANTIS, AVALON, BRENDAN, ELYSIUM, &c.

Islandshire, a part of Northumberland in England, embracing the Farne Islands, together with three parishes adjoining Berwick-on-Tweed (q.v.) and portions of two others. Area, 28,444 acres; pop. 3875. Till 1844 it formed a detached part of Durham county.

Islay, an island of Argyllshire, 13 miles W. of Kintyre, and $\frac{1}{2}$ mile SW. of Jura, from which it is separated by the Sound of Islay. Deeply indented on the south by Loch Indal (12 × 8 miles), Islay has a maximum length and breadth of 25 $\frac{1}{2}$ and 19 miles, and an area of 216 sq. m. It contains several small fresh-water lakes, and attains a height of 1441 feet. More than half the whole area is capable of cultivation, and great improvements have been effected in the way of road-making, draining, reclamation, &c. Dairy-farming, stock-raising, and whisky-distillation are leading industries; whilst slate, marble, iron, lead, and silver have been worked. In the course

of the century the old proprietors and the native tenantry have been largely superseded by newcomers. Islay has regular steamboat communication with Glasgow, and a telegraph was established in 1871. Pop. (1831) 14,982; (1891) 7335.

Isle of France. See MAURITIUS.

Isle of Man, Wight, &c. See MAX, WIGHT.

Isles, LORDS OF THE. See LORDS OF THE ISLES.

Isleworth, a Middlesex parish, on the left bank of the Thames, 12 miles WSW. of London. Here is Sion House, a seat of the Duke of Northumberland, the place where the crown was offered to Lady Jane Grey. Pop. 15,884.

Islington, a suburb of London, but so closely connected with it as to form part of it, is situated 2½ miles N. of St Paul's. Pop. (1861) 155,341; (1871) 213,778; (1891) 319,143. It is remarkable for the number of its religious, educational, and benevolent institutions. The Agricultural Hall (1861), where the great national cattle and horse shows are held, is capable of holding 50,000 people. In 1885 Islington was made a parliamentary borough. It returns four members to parliament, one member for each of its four divisions.

Ismail, a town and river-port in the Russian government of Bessarabia, stands on the north bank of the Kilia branch of the Danube, 48 miles from the mouth of that river. Formerly a Turkish fortress, it was taken and destroyed by Suwaroff in December 1790; came into possession of Russia in 1812; was assigned to Moldavia by the treaty of Paris, 1856, its fortifications being razed; and was transferred to Russia again by the Berlin Congress of 1878. It has an active trade in corn, wool, tallow, and hides. Pop. with the adjoining Tutchkoiff (1866) 31,779; (1897) 31,293.

Ismailia, a small town on Lake Timsah, through which the Suez Canal passes. It stands on the railway from Cairo to Suez and on the Sweet Water Canal. During the construction of the canal it was the headquarters of the work, having been founded in 1863, but it is now a place of only 1850 inhabitants.—The name Ismailia was also given to Gondokoro (q.v.) on the White Nile.

Ismailis, a Mohammedan sect. Like the rest of the Shi'ah, or party of Ali, they held that the dignity of Imâm, or head of the true faith, was inherent in the house of the Prophet and the line of Ali, the Prophet's cousin, son-in-law, and chosen lieutenant. They arose in Syria and Persia, taking their name from one Ismail, whom they regarded as the seventh and last of the Imâms, and who lived about 770 A.D. But the sect acquired its importance a century later from Abdallah al Kaddah, a Persian of Susiana, and son of Maimin. He was an oculist, a scholar, and an able juggler. The Ismailis had then no visible Imâm; indeed the Shi'ah lost its twelfth and last Imâm in the mysterious disappearance of Mohammed in 879 A.D. The idea of a 'Hidden Imâm,' destined to appear for the reformation of religion and of the world, thus became necessary for its existence. To undermine the whole empire, to prepare a great revolution and overthrow Islam was Abdallah's desire. His instrument was the faith in a 'Hidden Imâm,' or 'Mahdi,' 'Guided or Inspired One,' styled by Abdallah the seventh prophet, Mohammed having been the sixth. His many widely-spread dus or missionaries taught their converts that this coming deliverer had opened up the true and mystic meaning of the Koran. The teaching of all previous prophets was abrogated by him. Converts passing through their nine stages of instruction learned to deny all positive religion. Prayers, tithes, pil-

grimages, legal purity, and other religious observances were shown to have meaning and use for only the blinded crowd. A Demingus was declared to be the world's maker. The resurrection, the end of the world, final judgment, and rewards and punishments were mere allegories. The universe was eternal. Finally, belief was made absolutely free. Mohammed, the Chief, Hidden Imâm, Mahdi, or Seventh Prophet, son of Ismail, was, after all, not to appear but in his doctrine taught by his disciples and apostles; and the duty of all believers was to bring the world's sovereignty into the hands of these. Abdallah's son, Ahmed, succeeded him as Grand Master of the Ismailian Society. In his time a Babylonian peasant, Hamdan Karmat, joined it, became a missionary, a leader, and at length about 891 proclaimed a communistic system. For two centuries the Karmathians were the scourge of Islam and the East. An Ismailian missionary among the Berbers of Constantine called the people to arms in Ali's name. Obeidallah, a descendant of Abdallah al Kaddah, and Grand Master of the Ismailian Society, was put at the head of the revolution, before which the Aghlabite (809) and the Edrisite powers quickly fell; and, calling himself a scion of Ali, by Fatima the Prophet's daughter, was declared Calif and Mahdi. The rise of his dynasty, which is called the Fatimite, is the most remarkable example in history of the power of religious enthusiasm led by conscious imposture. Egypt (970) and Syria were added to its empire. The Karmathians recognised it and paid it tribute. Miserably decayed, it was supplanted in Egypt by Saladin in 1171. See also MAHDI.

Isma'il Pasha, Khedive of Egypt (q.v.) from 1863 to 1879.

Isobars. See METEOROLOGY.

Isochronism (Gr. *isos*, 'equal'; *chronos*, 'time'). A pendulum is isochronous when its vibrations are performed in equal times, whether these vibrations be large or small; but it can only possess this property by being constrained to move in a cycloidal arc. See CYCLOID.

Isoclinal Strata. See GEOLOGY, MOUNTAINS, STRATIFICATION.

Isocrates, the Athenian, who was born 436 B.C. and died 338 B.C., represents the perfection of 'epideictic' oratory—i.e. oratory in which form and literary finish count for everything, and matter for very little. Oratory, as a department of literature, was in Athens the outcome of that growth of litigiousness and development of the law-courts which characterised Athens from about the beginning of the Peloponnesian wars. The consequent necessity under which every Athenian was of being able to defend himself in a court of law first fostered the rise of a class of men—the Sophists—who professed to teach the art of argument, even to the extent of making the worse appear the better cause; and next, as the literary taste of Athenian juries increased, fostered the rise of a class who professed to teach the art of literary form, and who taught by example rather than precept. Hence 'epideictic' oratory, show-speeches. Such teachers of rhetoric have existed in other countries, but at no place and in no age have they reached the artistic excellence of Isocrates. This is partly due to the fact that, owing to the peculiar circumstances just explained, teachers of rhetoric in Athens at this time could gain the ear of the public, whilst elsewhere and at other times the teacher's audience has consisted of his pupils, and he has lacked the stimulus and the corrective of competent criticism. But though the hour had come, it might have sounded in vain had not the man been there. A brief summary of Isocrates' life will show that

nature had designed him for his work. If his speeches are deficient in practicality to an extent that has irritated Niebuhr for instance, it is because Isocrates was himself so utterly impractical. The son of a prosperous flute-maker, Isocrates received an excellent education, and in his youth heard the show-speeches made at Athens by the earliest epideictic orator, Gorgias. He also listened to the lectures of the philosopher Prodicus, and joined the circle of Socrates, and he only coquetted with philosophy, and though in the *Phaedrus* of Plato Socrates expresses the highest expectations of him, Isocrates abandoned philosophy. He then took to speech-writing as a profession, but he had none of the talents required in the composition of speeches having such a practical object as that of winning a case in a law-court. After trying his hand at six such speeches (402-393 B.C.) he abandoned logography. If he failed in writing practical speeches to be delivered by others, he was still less adapted by nature to deliver his own speeches himself and follow a political career; his voice was too feeble, and he was much too nervous. Other people since Isocrates having failed in other pursuits have betaken themselves to schoolmastering, but Isocrates deserves the credit of having been the first to discover this resource. About 390 B.C. he set up as a teacher of oratory, though he did indeed profess, in the speech which served as his prospectus (*Against the Sophists*), to give a general practical education. In his prospectus he was careful to distinguish himself from such shallow pretenders as the Sophists on the one hand, and on the other from such impractical teachers as philosophers. This sample of his skill as an artist in words, though it drew from Plato (*Euthydemus*, 301, D) some contemptuous animalversions on the little knowledge of certain persons who cultivate the domain intermediate between philosophy and politics, succeeded in drawing to him pupils who subsequently became distinguished, statesmen such as Timotheus and Laodamas, historians such as Ephorus and Theopompus, orators such as Isæus, Lycurgus, Eschines, and Hyperides. Pupils paid him 1000 drachmæ, and were put by him through a course of three or four years' duration. He himself composed model speeches for them, such as the *Panegyricus* (about 380 B.C.) and the *Platæicus* (373), and corrected the oratorical exercises composed by them. But he also wrote speeches intended to be practical: one of them, the *Archidæicus* (365 B.C.), may actually have been composed for and delivered by the Spartan king, Archidamus, but the majority, for instance the *Symmachæicus* (357 or 355 B.C.), the *Areopagitæicus* (about 354 B.C.), the *Panathenæicus* (342-339), and the letters to Philip of Macedon, were not designed to be delivered but to be circulated and read; they are in fact the earliest political pamphlets known. As a politician, or rather a would-be politician, Isocrates has only one idea, and that an utterly impracticable one—to unite all Greeks together in a joint attack upon the common foe, Persia. The practical commentary on this ridiculous Pan-Hellenistic panacea was the destruction of Greek freedom on the field of Charonea by the very Philip to whom Isocrates looked to make his nostrum effective. 'That dishonest victory,' in the words of Milton, 'killed with report that old man eloquent.' Isocrates did indeed die shortly after the news of the battle at the age of ninety-four, but it may be doubted whether it was the news that killed the schoolmaster. Unpractical Isocrates certainly was. Alexander conquered Asia in less time than it took Isocrates to write a single speech (the *Panegyricus*). But it was this very characteristic which made the oratory of Isocrates what it is. And Milton's tribute to him may serve to remind us that, in the

opinion of all competent judges, for melody, artistic merit, perfection of form and literary finish, Isocrates stands unrivalled. He has of course the defects of his qualities. His work may be finished, but it is undeniably laboured. He may have melody, but it is apt to become monotonous. He is always smooth, even where he ought to be stormy. Such perfection of form as he attained could only be produced by an artist who was willing to sacrifice everything else to it, and Isocrates by nature did readily incline to do so. A few obvious generalities and a few moral sentiments were all that he required in the way of matter for a speech; indeed for many speeches. The result is that having read one of his speeches you have read all. The truths of morality are indeed eternal, but they will not bear eternal repetition. Had but one of his speeches survived, his poverty of thought would never have been discovered, but fate with cruel kindness has preserved nearly everything he ever wrote. But if Isocrates is too beautiful to be absolutely perfect himself, we must not forget that to appreciate his services to Greek literature we must not consider him apart from the history of Greek oratory. He demonstrated once and for all, and at precisely the time when the demonstration was necessary, that prose as well as poetry may have an artistic beauty, may have rhythm, flow, and melody of its own. It was worth a lifetime's labour to effect this; and if it was only in Demosthenes that this outward beauty came to be wedded with nobler and with manlier qualities, let us remember that it were as vain to expect the fruit without the blossom as to imagine that we could have had Demosthenes without Isocrates.

The first edition was printed at Milan in 1493. The best edition of the text is that in the Teubner series. There are excellent English notes on the *Demonæicus* and *Panegyricus* by J. E. Sandys, German notes by Rauchenstein on the latter and the *Areopagitæicus*. There is an English translation by Freere (1894 *et seq.*).

Isodynamic, Isoclinic, and Isogonic Lines (Gr. *isos*, 'equal'; *dynamis*, 'force'; *klinô*, 'I bend'; *gonia*, 'an angle'), or lines of equal force, equal inclination, and equal declination, are three systems of lines, which being laid down on maps represent the magnetism of the globe as exhibited at the earth's surface in three classes of phenomena, the varying intensity of the force, the varying dip or inclination of the needle, and its varying declination from the true meridian. See MAGNETISM.

Isola Bella, ISOLA MADRE. See BORROMEAN ISLANDS.

Isola Grossa, or ISOLA LUNGA (Great or Long Island), a long, narrow island, 27 miles by 3, running parallel to the coast of Dalmatia, over against Zara. It belongs to Austria. Pop. 12,000.

Isomerism (from the Greek word *isomêrês*, 'composed of equal parts'), the relation between chemical compounds which are identical in their ultimate or percentage composition, but present differences in their chemical properties. Isomeric compounds, or *isomerides*, are divisible into metameric compounds, or *mutamerides*, and polymeric compounds, or *polymerides*.

In all metameric compounds the molecular weight is the same, while in all polymeric compounds the molecular weights are simple multiples of the molecular weight of the lowest member of the group. As an illustration of metameric compounds, propionic acid, C_3H_5COOH , acetate of methyl, CH_3COOCH_3 , and formic ether, $HCOOC_2H_5$, may be taken. Their rational formulae, which express their probable constitution, are perfectly distinct, yet they all have the same percentage composition, the same empirical formula, $C_3H_6O_2$, and the same molecular weight (74).

As an illustration of polymerides, the hydro-carbons homologous with olefiant gas may be taken. Olefiant gas is represented by the formula C_2H_4 , propylene by C_3H_6 , butylene by C_4H_8 , amylene by C_5H_{10} . These substances have the same percentage composition, but different molecular weights.

The carbohydrates, which are represented by the general formula $C_nH_{2n}O_n$, present well-marked examples of isomerism. Thus, cellulose, $C_6H_{10}O_5$, starch, $C_6H_{10}O_5$, and gum, $C_6H_{10}O_5$, are metameric; while grape-sugar, $C_6H_{12}O_6$, possesses the same percentage composition, but twice as high a molecular weight, as lactic acid, $C_3H_6O_3$, and the same percentage composition, but three times as high a molecular weight, as acetic acid, $C_2H_4O_2$; hence the three last-named substances are polymeric.

The most recent researches have brought to light the existence of several special varieties of isomerism. A *tautomeric* body is one in which the reaction to some reagents is as if certain hydrogen atoms were in one place in the molecule, while to others it is as if the hydrogen occupied a different position; and a tautomeric body may be *desammeric* when it can be prepared in recognisably different forms, differing from one another in the position of these wandering hydrogens. *Allotomeric* bodies have a similar chemical structure, but the geometrical symmetry is different, as in the following case (in which the symbol X stands for the group COOH):

The question of geometrically symmetrical or asymmetrical arrangement of atoms in a molecule has become, in the hands of Wislicenus and others, one of considerable importance in reference to isomerism. Quite possibly the allotropic modifications of some of the elements (see ALLOTROPY) are really isomeric differences of arrangement of the atoms within the molecule (q.v.). See also AROMATIC SERIES and CHEMISTRY (Vol. III, p. 152).

Isomorphism (derived from the Greek words *isos*, 'equal,' and *morphe*, 'form') strictly signifies similarity of form, but it is now restricted by chemists to those substances which are not only similar in their crystalline form, but are also analogous in their chemical composition. The diamond, C, magnetic oxide of iron, $FeO.Fe_2O_3$, and potash-alum, $K_2SO_4.Al_2(SO_4)_3.24H_2O$, all crystallise in octahedra, but there is obviously no analogy in the chemical composition of these substances; on the other hand, the spinelle ruby, $MgO.Al_2O_3$, magnetic oxide of iron, $FeO.Fe_2O_3$, and chrome ore, $FeO.Cr_2O_3$, not only crystallise in octahedra, but (as their formulae show) are also analogous in their chemical composition. Hence the members of the latter group, not the former, are truly isomorphous in the restricted sense. As further examples we may quote the elements arsenic, antimony, and tellurium; the chloride, bromide, iodide, and fluoride of potassium; the sesquioxides of aluminium, iron, chromium, and manganese; and for additional lists refer to Miller's *Chemical Physics*. In most cases, as Mitscherlich (to whom we owe most of our knowledge of this subject) showed, the chemical composition of substances that correspond in form is analogous; and that chemist further endeavoured to prove that crystalline form is independent of the chemical nature of the atoms, and that it is determined solely by their grouping and relative positions; the same number of atoms combined in the same way always producing, according to him, the same crystalline form. The coincidence of similarity in

crystalline form with similarity in atomic arrangement is the most important generalisation yet arrived at in the science of crystallography; and in chemistry it has been of essential service in facilitating the classification of compounds, and to some extent in determining the combining numbers or atomic weights of the elementary bodies.

Isopoda (Gr., 'equal-footed'), an order of higher Crustaceans in the division with unstalked eyes. The body is usually flattened, and the first pair of abdominal legs form a lid overlapping the others, which generally bear gills. They are mostly marine, but the wood-lice are terrestrial; they live mainly on decaying animal matter, but many are parasitic. The genus *Tanais* seems ancestral and primitive; *Asellus* is very common, both in fresh and salt water; the griddle (*Limnoria*) bores into wharf-posts and ship-sides; *Idotea* includes the largest forms with adaptive colours and sometimes phosphorescence; the family Bopyridæ are parasitic on other Crustaceans, and have very small males; the family Egidæ includes many 'fish-lice,' some of the parasitic Cymothoidæ are first male and then female. The Oniscoidæ are terrestrial, and feed on decaying vegetable matter; they are familiarly known as 'wood-lice,' 'sow-bugs,' 'pill-bugs,' 'slaters,' of which *Oniscus*, *Porcellio*, and *Armadillo* are common genera. See CRUSTACEA, FISH-LICE, WOOD-LICE.

Isothermal Lines. See TEMPERATURE.

Isotropism, physical homogeneity or amorphism; identity of elastic forces of propagation of vibration (light, heat, sound), or identity of susceptibility to magnetisation, in all directions.

Ispahân, properly ISFAHÂN, a famous city of Persia, capital of the province of Irak-Ajemi, and formerly capital of the entire country, is situated on the Zenderud, in an extensive and fertile plain, 226 miles S. of Tehran. The river, here 600 feet broad, is crossed by three noble bridges, one of them 1000 feet in length, with 34 arches, but now sadly in decay. Groves, orchards, avenues, and cultivated fields surround the city for miles; but the permanent beauty of the vicinity only serves to make the contrast all the more striking between the former splendour of the city and its present ruinous condition. Miles of street are now almost tenantless, and many of the palaces are deserted and rapidly falling to decay. The suburb Julia, on the southern bank of the river, once a flourishing Armenian settlement of 30,000 inhabitants, is now little better than a mass of ruins, since most of the Armenians have migrated to India. Ispahân, however, is still an important city and the seat of extensive manufactures, including all sorts of woven fabrics, from rich gold brocades and figured velvets to common calicoes. Trinkets and ornamental goods in great variety, with firearms, sword-blades, glass, and earthenware, are also manufactured. Of late years, too, Ispahân has shown considerable signs of improvement; many of its edifices have been rebuilt; rice, an important article of commerce, is now largely cultivated in the neighbourhood. Pop. estimated at 60,000.

Ispahân was a trading town of importance, and the capital of Irak, under the califs of Bagdad. It was taken by Timur in 1387, when 70,000 of the inhabitants are said to have been massacred. During the 17th century, under Shah-Abbas the Great, it became the capital of Persia, and reached the climax of its prosperity. Its walls were then 24 miles in circuit, and it is said to have had between 600,000 and 1,000,000 inhabitants. It was then the emporium of the Asiatic world; the merchandise of all nations enriched its bazaars, and ambassadors from Europe and the East crowded

its court. In 1722 it was devastated by the Afghans, and some time afterwards the seat of government was transferred to Tehran (q.v.). The importance of the place is likely to rise through the opening of the Karun River, since the main road leading from Mohammera to the interior of Persia will pass Ispahan. Ispahan is besides the religious centre of Persia, as the Imam Djunaa (high-priest) residing here is looked upon as the greatest ecclesiastical dignitary of the Shiite world.

Israel. KINGDOM OF. See JEWS.

Israëls. JOSEF, genre-painter, was born at Groningen in 1824. He studied at Amsterdam under Pfeneman and Krusenman, and in Paris under Picot and Henri Scheffer. In 1855 his 'William, Prince of Orange, opposing the Decree of the King of Spain' attracted attention in the Exposition Universelle. But this work was almost the only effort of the painter in the direction of historical art; for he soon turned to scenes from humble life, and settling at Katwijk near Leyden he devoted himself to the portrayal of the fisher-folk, sending to the Salon of 1857 his 'Children of the Sea' and his 'Evening on the Shore.' In 1867 his celebrated 'Interior of the Orphan Asylum at Katwijk' gained for him a third-class medal and the ribbon of the Legion of Honour; and eight years later he was awarded the cross and a first-class medal. More recently he has resided at The Hague, working indefatigably, and producing a long series of genre-pictures in oils and water-colours, presenting, usually in its pathetic aspects, the life of the humbler classes of Holland. At first his work was somewhat violent in colour, but gradually it has become subdued, harmonious, and lovely; his management of the restricted tonality which he has adopted shows the most accomplished artistic skill; and his handling is large, vigorous, and unlaboured. Among his chief pictures may be named 'The Sewing-school at Katwijk' (1881), 'Silent Company' (1882), 'Fine Weather' (1883), and 'The Struggle for Life' (1883). He is also favourably known as an etcher by 'Old Mary,' 'The Cradle,' 'The Mother,' 'The Fisherman,' and other plates very simple, direct, and painter-like in their method. See a monograph by Net-scher, with etchings by Steelink (French trans. by Zileken, Amsterdam).

Issik-kul (Kirkiz, 'warm water'), a lake in central Asia, in the Russian province of Semiryetchensk, situated, at an elevation of 5000 feet above sea-level, between the Terskei Ala-tan range on the south and the Kungei Ala-tan on the north. It measures 112 miles long, 38 miles broad, and covers an area of 1980 sq. m. Its water is very salt, but full of fish, especially carp. Notwithstanding the fact that it receives forty or more rivers, its surface falls permanently at the rate of 8 or 9 inches a year.

Issoire (anc. *Issiodorum*), a town in the French department of Puy-de-Dôme, near the confluence of the Couze and Allier, 21 miles by rail S.E. of Clermont Ferrand. Pop. 6051. The town and its people were treated with savage fury by both parties during the religious wars after the Reformation (1574-77).

Issoudun, a town in the French department of Indre, 72 miles S. of Orleans by rail, has manufactures of parchment, cloth, agricultural instruments, &c., and quarries of lithographic stone. Pop. (1872) 11,913; (1886) 12,697; (1891) 11,431.

Issue, in Law, means the point of fact in dispute which is submitted to a jury.

Issus, anciently, a seaport on a gulf of the same name in Cilicia, Asia Minor, celebrated for

the victory which Alexander the Great obtained here over Darius (333 B.C.), by which the camp and treasure and family of Darius fell into his hands.

Issy, a village in the French department of Seine, half a mile SW. from Paris, with which it is connected by a tramway, possesses a seminary, a retreat for old men, a castle, and manufactures of waxcloth, chemicals, &c. Pop. (1886) 12,080. Here on 3d July 1815 Bliicher defeated Davout. In 1870-71, during the siege of Paris by the Germans, the fort of Issy suffered severely from the artillery fire. It has since been re-erected, and now forms part of the south-west defences of Paris.

Istakhr, or STAKHR, an ancient city of Persia, built near Persepolis (q.v.).

Istamboul. See CONSTANTINOPEL.

Isthmus, in Geography, a narrow neck of land joining two larger portions, as the Isthmus of Suez and the Isthmus of Panama. The name was often employed by the ancients without any addition to designate the Isthmus of Corinth, joining the Peloponnesus to continental Hellas. Here were celebrated the Isthmian Games, one of the four great national festivals of Greece. See ATHLETIC SPORTS.

Istria, an Austrian margraviate, forming a peninsula in the north-east corner of the Adriatic Sea, between the Gulf of Trieste and the Gulf of Fiume or Quarnero. Although a mountainous land, often swept by the sirocco and bora winds, it yields excellent olive oil and wine. Area, with the adjacent islands, 1812 sq. m.; pop. (1880) 292,000; (1885) 299,911, many of whom are engaged in seafaring life. Capital, Rovigno.—For Dora d'Istria, see GHKA.

Itacolomite, a schistose quartzite, containing scales of mica, talc, and chlorite, which are often so arranged as to give a certain flexibility to the rock (*flexible sandstone*). In Brazil and the south-eastern states of North America itacolomite is the matrix in which diamonds are found.

Italian Architecture. This term is usually limited to the style practised by the Italian architects of the 15th, 16th, and 17th centuries, and since adopted in every country in Europe. The style originated in a revival of the ancient architecture of Rome. Although Gothic architecture had been practised in Italy during the 13th and 14th centuries, it had never been thoroughly naturalised. The Italians always showed a preference for the round arch over the pointed northern form; and even in the buildings they erected in the pointed style there is a certain simplicity and largeness of parts indicative of a classic feeling. As early as 1350 Giovanni Pisano, in the beautiful sculpture of the pulpit in the Baptistery at Pisa, showed a return to the ancient models. Arnolfo di Cambio planned the cathedral of Florence (1290-1300), and in his design proposed a great dome (a remarkably Roman feature) over the crossing of the nave and transept. This he did not live to complete; but he prepared the way for Brunelleschi (q.v.), who went to Rome to study the ancient buildings there, at that time neglected and hardly known to the Italians themselves, and ultimately, notwithstanding great opposition, succeeded in carrying out the construction of the dome as it now stands. From this time the revival of Roman architecture went on rapidly. It was encouraged by the popes and other princes of Italy; and the invention of the printing-press soon spread a knowledge of the works of the Italian architects over Europe. At first the Roman mouldings and ornaments only were copied and applied to the

existing forms. As the ancient style became better understood its general principles were gradually adopted, until at length the Modern Italian style was formed. This style may be defined as ancient Roman architecture applied to the forms and requirements of modern buildings. It has been admirably applied to domestic, but it has never been so successfully used in ecclesiastical edifices.

Library of St Mark's, Venice, by Sansovino. Ricardi Palace, Florence, by Michelozzo.

The domes of the Italian churches render the interiors of these buildings very impressive, and are a feature, for the introduction of which into the west of Europe we are indebted to this style; but the facades of the churches are broken up into stories, and want the unity of a Gothic front.

Italian architecture is divided into three styles or schools, according to the places where it was practised—viz. the Florentine, Roman, and Venetian. The Florentine buildings are massive and grand in effect; they are indebted to ancient Roman art chiefly for details, the outlines being the same as those of the older buildings, designed to suit the requirements of the locality. Florence being a turbulent city, every man who had anything to lose had literally to make his house his castle. Accordingly, the basement floor is massively built with large blocks of stone, and the windows are small and plain. The Roman school naturally resembles more closely the ancient Roman buildings so numerous in that city—pilasters, arcades, &c. being freely used. In Rome the plan of including two or more stories in one order of columns or pilasters with their entablature, having an attic or low story above, first originated, and was afterwards extensively, but, as already explained, not successfully applied to churches.

The Venetian style is, as might be expected in a city long accustomed to elegant palaces, the most ornate and picturesque of the Italian schools. Venice is crowded with specimens of all kinds from the earliest to the latest Renaissance, and retains its individuality of style from first to last. Each story is marked by a separate tier of columns or pilasters with their entablature; the windows are arched and ornamented with columns, and the spandrels commonly filled with figures. The outline is varied in form, and is usually finished with a balustrade, broken by pedestals, and crowned with sculptured figures. It is from this most picturesque of the styles of the Italian Renaissance that the other countries of Europe derived their peculiar forms. See RENAISSANCE, ELIZABETHAN, PALLADIO.

Italy. The kingdom of Italy comprises the central of the three great peninsulas of southern Europe (excepting the small republic of San Marino, q.v.) together with Sicily, Sardinia, and some smaller islands. Knit to the solid mass of central Europe by the Apennines, the peninsula projects south-eastward into the Mediterranean like a magnet, drawing to itself in ancient times the lordship and commerce of the whole sea, and serving as the avenue by which the culture of the East was carried into northern and western Europe. At the Strait of Otranto Italy approaches within less than 50 miles of Albania. The boundaries of the peninsula are on the W. and S. that portion of the Mediterranean known as the Tyrrhenian Sea, and on the E. the Adriatic; on the N. the Alps stretch from the head of the Adriatic to the Riviera, and almost without a break shut in the kingdom from Austro-Hungary, Switzerland, and France. The peninsula itself extends from 46° 40' 12" N. lat. (Monte Trugnoni in the Carnian Alps) to the southernmost point of Calabria, an unnamed headland in 37° 54' 54" N. lat., or 24' farther south than Cape Spartivento. The extreme eastern point is the Cape of Otranto, 18° 30' 37" E. long., and the western Monte Tabor, 6° 33' 7" E. Its greatest length in a direct line is 710 miles; the breadth ranges from 351 miles in the north to about 20 between the Gulfs of Sta Eufemia and Squillace, but in most places is about 90 or 100 miles. The seaboard of the peninsula extends to 2272 miles, that of the islands to 1944 miles; in 1890 the frontier with France was returned at 307 miles, with Switzerland at 407 miles, and with Austria at 466 miles.

The area of the kingdom of Italy was formerly given officially as 114,416 sq. m., but the data on which this estimate was based were known to be inexact. Strelbitsky, in his *Superficie de l'Europe* (1882), made the area 111,410 sq. m.; his calculations were revised by the Italian Military Geographical Institute in 1884, and the total area of the kingdom was still further reduced to 110,657 sq. m., made up as follows: Continental and peninsular Italy, with the small islands embraced in its administration, 91,422 sq. m.; Sicily and the islands administratively dependent on it, 9939 sq. m.; Sardinia and the islets near it, 9296 sq. m. These are the official figures for the entire kingdom; but as yet no detailed survey has been accomplished, and the areas given for the provinces in the table below are those obtained by Strelbitsky's calculations. At the first general census of the kingdom, in 1871, the population was 25,801,151. The table gives the population actually present at the census of December 31, 1881 (density 257 per sq. m.); in 1895 the estimated population was 30,913,670. The number of foreigners in Italy at the time of the census of 1881 was 59,956, including 16,992 Austrians, 12,101 Swiss, 10,781 French, and 7302 British. The Italian population includes in Piedmont about 120,000 of French, and some 3000

of Teutonic origin, in Southern Italy at least 60,000 of Albanian and 20,000 of Greek origin, and in Sardinia 7000 or 8000 of Spanish origin. (A list of

the pretty numerous places in the Neapolitan and Sicilian provinces where Albanian, an Italianised Modern Greek, Gallo-Italic, Provençal, and Illyrian are still in use as 'linguistic islands,' will be found in a paper contributed by Prince Lucien Bonaparte to the Philological Society, March 1890.) The estimated population at the end of 1889 (see table) was 30,947,306; but this is based solely on the difference between births and deaths, and takes no account of emigration. Within the eight years 1882-89, 791,404 persons left Italy for different parts of America, as many as 113,066 emigrating in 1889 alone. In 1888 the United States received 47,856; Argentina, 75,029; Brazil, 104,353. Of the 1881 population 501 in every 1000 were males. In the accompanying table the old *compartimenti* or groups of provinces are retained for convenience, although they are no longer recognised as administrative divisions. The area is nearly that of Great Britain and Ireland; the population about four-fifths that of the United Kingdom at the same date. To the kingdom proper must be added Italy's colonial possession in Africa. This consists of the territories of Assab and Massowah (q.v.), on the Red Sea, Keren and Asmara in Abyssinia, and the Dahlak archipelago, which embrace a total area of nearly 4000 sq. m., and were united into a colony bearing the name of Eritrea in 1889. Moreover, Italy established a protectorate for some distance inland from Massowah, and along the coast from Ras Kasar (18° 2' N.) to beyond Assab, and till the disastrous events of 1896 claimed to have established a protectorate over Abyssinia.

The towns with a population of over 100,000 in 1881 were Naples, 463,172; Milan, 295,543; Rome, 273,268; Turin, 230,183; Palermo, 205,712; Genoa, 138,081; Florence, 134,992; Venice, 129,445; and Bologna, 103,998. In 1895 the estimated populations were: Naples, 523,000; Rome, 453,000; Milan, 433,000; Turin, 336,000; Palermo, 277,000; Genoa, 217,000; Florence, 200,000; Venice, 150,000; Messina, 147,000; Bologna, 142,000. The seat of government was at Turin from 1861 to 1865, then at Florence till 1870, since which date Rome has been the capital of the kingdom.

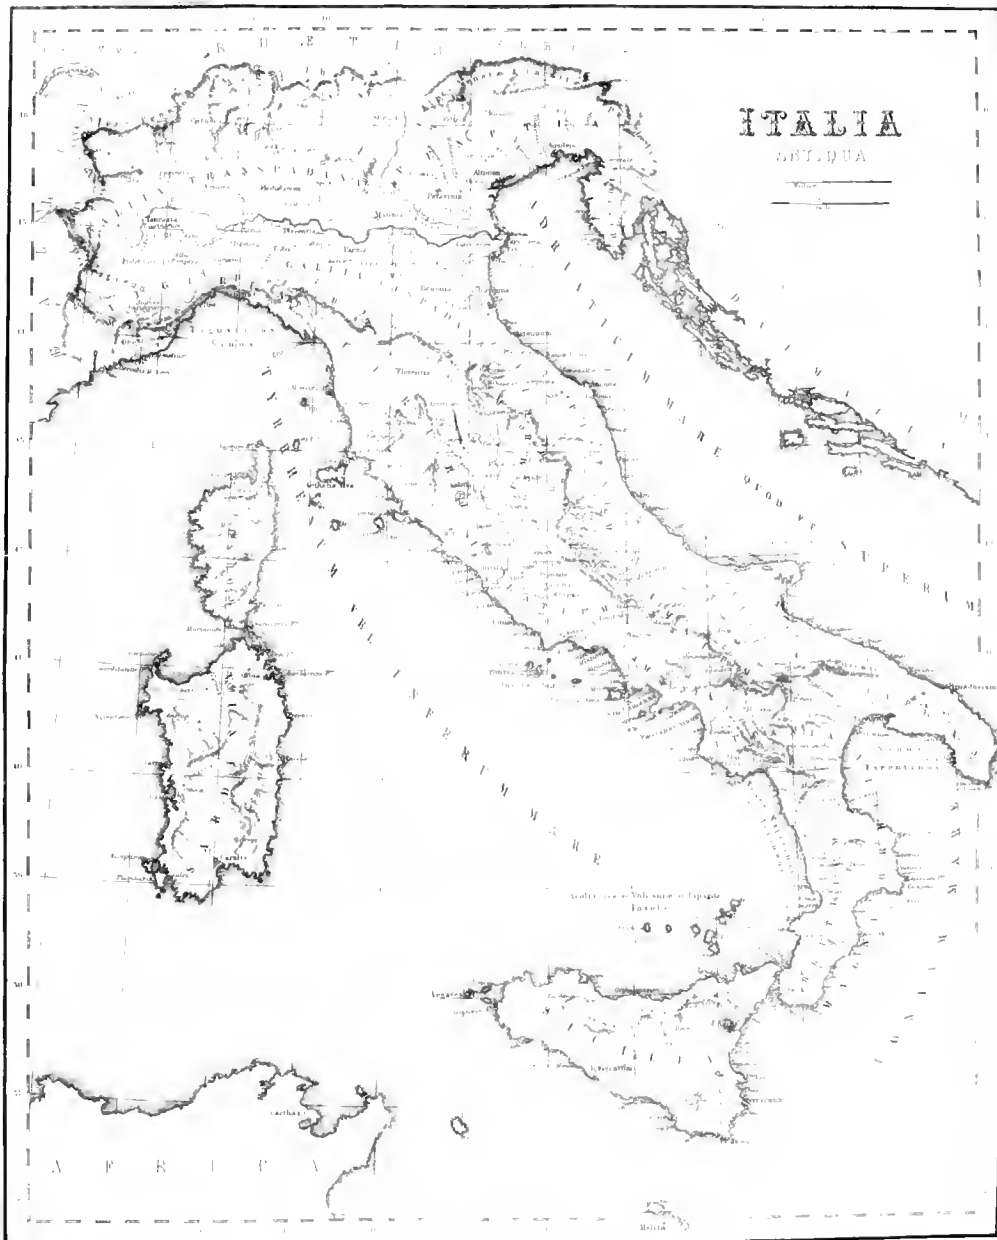

Physical Features.—The configuration of continental Italy (for the islands, see SARDINIA and SICILY) may be easily explained; in the peninsular portion it is determined mainly by the great chain of the Apennines. It is usual with geographers to divide the country into Northern, Central, and Southern Italy, the middle section generally being taken to extend between Spezia and Cape Circello on the west coast and Rimini and Monte Gargano on the east coast. This division, however, especially as regards its southern boundary, is purely arbitrary, and it will be more convenient in this article, while retaining the terms commonly in use, to describe the country under the two divisions into which physically it falls—the great plain of Northern Italy, and the generally mountainous peninsula to the south.

On the northern frontier the Alps sweep round in a mighty arc from Nice to Trieste, running out in places into Piedmont, Lombardy, and Venice. For the most part they rise steep and abrupt, except where their wall is pierced by long, deep valleys; and some of the loftiest peaks in the system, including Mont Blanc and Monte Rosa, belong to this mountain-girdle. The highest mountain entirely within the kingdom is Gran Paradiso (13,652 feet), the culminating point of the Graian Alps, in Piedmont. Between the Alps and the Apennines spreads the broad fertile Lombardo-Venetian plain, a nearly level country, which differs altogether in character from the peninsula to the south, and for a long period was politically distinct from it. Most of this great

alluvial tract, which fills nearly the whole of Northern Italy, belongs to the basin of the Po; it is irrigated by numerous streams and canals, and is one of the most fruitful and flourishing districts of Italy. The principal rivers are fed from the Alpine lakes; and the Po (q.v.), which descends from Monte Viso, on the western frontier, and, as it sweeps across the plain, receives the contributions of numerous important streams, ranks for its volume of water among the notable rivers of Europe. It is navigable for 320 out of its 420 miles, and several of its tributaries are also navigable. The Adige, which is connected with the Po by canals, is also, although much more rapid, navigable in its lower course, and so is the Brenta; the other streams that pour down through the Venetian plain are mostly mountain-torrents. The lakes of Northern Italy belong to a different class from those of the peninsula. Many of the Po's tributaries spread out at the foot of the Alps into considerable bodies of water, among which are the Lago di Garda (127 sq. m.), Lago Maggiore (81), and Como (58). These lakes are all remarkable for their depth; Maggiore is reported to have a depth of 1158 feet, Como 1358, and Garda 1916 feet. From Rimini to the Gulf of Trieste the coast is flat and marshy from the overflow of the rivers, and fringed, both north and south of the muddy delta of the Po, for long distances by lagoons. These lagoons are in general separated from the sea by only a narrow strip of sand, with openings at intervals, and contain some important harbours, such as Venice and Chioggia. On the opposite coast, along the Riviera, from Nice to Spezia, the sunny, rugged mountains come close to the water's edge, the only considerable portions of level ground occurring at the mouths of valleys. The Apennines shut out this district from the rest of Northern Italy, and from their proximity there are no large streams along the coast here. The geology of the north and west of Northern Italy is that of the Alps (q.v.). In the basin of the Po there are vast moraines left by the glaciers of the Glacial Period; and the isolated Monti Berici and Euganean Hills, in the plain north of the Adige, are of volcanic origin.

In the peninsula the Apennines are the most important feature. The chain, after stretching across from the Gulf of Genoa to the Adriatic, turns and runs down in a broad, irregular mass to the extremity of Calabria, but does not extend into the 'heel' towards Otranto. Its highest point before it makes its bend is Monte Cimone (7110 feet); but the mean elevation is only some 5200 feet, and the principal summits of the range occur in Central Italy. Here it no longer presents a continuous ridge, but is broken into mountain-masses and short ranges, marching in a roughly parallel direction, and separated by extensive upland valleys. The limestone rocks of the Apennines, rugged and cleft, fill the interior of the country with picturesque mountain-scenery, which becomes wilder as the chain stretches farther south, and in the Neapolitan highlands exhibits a savage grandeur, that is softened somewhat by the fertile 'red earth,' formed from the disintegrated limestone. In Central Italy the main chain follows the Adriatic side, and its eastern slope is the steeper; the western is less abrupt, and contains numerous valleys. The culminating peak of the Apennines is Monte Corno (9577 feet), in the great mountain-mass called Gran Sasso d'Italia. The bold promontory of Monte Gargano (once an island) does not belong to the Apennine system. The Neapolitan Apennines fill the rest of the peninsula, crossing over to the west coast, and running close upon the sea again, as in Northern Italy; but the system properly ends with Monte Pollino (7376), where the

Calabrian peninsula begins; for here the limestone, except at long intervals, gives place to granite, gneiss, and crystalline schists—to reappear, however, in the mountains of Sicily, which may be looked upon as a continuation of the range (for the geology, see APENNINES). On the west side of the peninsula, between the main chain and the sea, a volcanic tract extends from the isolated trachytic cone of Monte Amiata (5689), in Tuscany, to the Monti Laziali, and as far south as Vesuvius (4206), the only volcano still active. The entire Campanian plain, the Roman Campagna, and the country round Viterbo are mainly of volcanic origin; and throughout this tract are a number of small lakes occupying crater-shaped basins. The only volcanic peak east of the main chain is Monte Vulture (4364), somewhat farther north than Vesuvius. To the volcanic centres within the peninsula may be added Etna in Sicily, and Stromboli in the Lipari Islands. Tuscany is a hilly country, which seldom rises into mountains. Farther south the Roman plain, the Pontine Marshes, and the fertile Campanian plain are connected, with unimportant breaks; but on the east side of the Apennines the only plain is that of Apulia, which rises into undulating downs, and, in the peninsula to the north-east of the Gulf of Taranto, into low, barren hills of Pliocene formation. North of Apulia stretches of vine-clad hills occupy the country between the mountains and the Adriatic, until the lowlands of Northern Italy are reached.

The rivers of the peninsula present a striking contrast to those of the northern plains. Here are no such inexhaustible reservoirs as in the lakes and snowfields of the Alps, nor is the rainfall of importance save in the winter months; so that even the larger lowland rivers, except the Tiber, fall considerably in summer, and in the south what are torrents after heavy rains often in the dry season disappear altogether. The chief rivers of the peninsula flow into the Tyrrhenian Sea; but only the Tiber (for 90 miles) and, to a less extent, the Arno (66 miles), Volturno, and Garigliano are navigable. The lakes of the peninsula are either crater-lakes, such as that of Bolsena (45 sq. m.), or occupy troughs among the mountains. To the latter class belongs Trasimeno or the Lago di Perugia (52 sq. m.); Fucino or Celano, which was a larger lake, has been drained, and is now cultivated. The coast along the Adriatic extends unbroken, except where the Gargano promontory forms the Gulf of Manfredonia; and on this side the only harbours, unless we include Ancona, are Brindisi, Barletta, and Bari. Taranto is one of the best harbours in Italy. A vast fertile plain, but infested with malaria, adjoins the gulf of that name; while nearly everywhere in Calabria the coast, though richly clothed with southern vegetation, is more or less steep, and the only port is Reggio, on the Strait of Messina. To the north are the Gulfs of Policastro, Salerno, Naples, and Gaeta, that of Naples, sheltered by the islands of Ischia and Capri, being especially well provided with harbours. In Central Italy the west coast contains several long, shallow bays, divided by promontories which have been formed by alluvial deposits connecting rocky islands with the mainland; but still farther north, along the Riviera, the steep coast presents a number of admirable harbours, such as Spezia, Genoa, and Savona.

Climate and Vegetation. The generally warm climate of Italy is considerably modified in places by the presence of the mountain ranges or the proximity of the sea. The plain of the Po, open to the icy winds from the Alps, and closed to those from the south, has a cold if short winter (the mean winter temperature of Turin is nearly the same as that of Shetland), while along the Riviera the temperature is as high as, and sometimes higher

than, that of Rome or Naples. Throughout the peninsula the temperature is lowered by the presence of the Apennines, and some of the coldest districts of Italy are found in the Marches and in the Abruzzi uplands. Moreover, the Adriatic coast, exposed to the north-east winds, is colder than the corresponding west coast. July is in general the hottest month, but in the extreme south August; the coldest month in every province is January. The highest temperature recorded is 109° F. (in Apulia), the lowest -25° F. (on Monte Stelvio, in Lombardy); but over the whole country the extremes of mean annual temperature for the period 1876-88 were only 46 and 62° F. With regard to the rainfall a considerable difference is observable in the various sections of the country. In the very south there are but two seasons, a wet and a dry; whereas in Northern Italy there are two greater and two lesser rainy periods in the year, most rain falling in October and in spring, and least in winter. Over all the peninsula autumn is the wet season; but in the islands most rain falls in the winter months. The lowest mean annual rainfall is in Foggia (18 in.) and Sardinia (17); the highest in the Venetian province of Udine (60 in.), and in Bergamo and Novara. The distribution of moisture is very unequal, even in districts near one another (the yearly mean of Venice itself is less than half that of Udine); but in general most rain falls in the mountains. Snow is common in the basin of the Po, becoming less so as we proceed south, except in the uplands, where in some districts it lies for months. The cold mistral blows in the Gulf of Genoa, and the scorching sirocco affects the coast sometimes as far north as Venice. The singular clearness of the atmosphere, enhancing the charms of buildings and of landscape, strikes every visitor; but in many districts the evil presence of malaria, from July to October especially, forms a serious drawback to the sunny climate. Indeed, some of the most fertile tracts of Italy, as in Calabria, have for centuries lain deserted owing to this plague. Only six districts ('*circondarii*') are altogether free from malaria, and the malignant type infests the Adriatic lagoons, the Tuscan Maremma, the Roman Campagna, Apulia, most of the Calabrian coast, and Sicily and Sardinia. In 1887 no less than 21,033 deaths were set down to malarial fever. In the Campagna and elsewhere, however, drainage operations have had a good effect.

The vegetation of Northern Italy is in the main such as can endure the frosts of winter. But by the lake sides we find orange and olive trees, and the summer heat is sufficient to ripen rice and maize, of which, as well as other cereals and legumes, large crops are raised. Forests of chestnuts clothe the mountains, vineyards the lower hills, and the mulberry tree is extensively grown. The Riviera, so far as vegetation is concerned, belongs to Southern Italy, and the date-palms and orange-trees are continued at slight intervals along the Tuscan coast. In the interior of Central Italy, however, the vegetation still presents much the same features as in the Lombard plain, and it is only in Southern Italy that the Mediterranean flora prevails. Here, in the lowlands from Monte Gargano and Terracina south, the flora of central Europe gives place to palms and orange and lemon and citron trees, the cactus and agave, laurels, myrtles, olanders, and forests of arbutus and the evergreen oak. Only at elevations above 2600 feet do the chestnut and oak reappear, and higher still the beech; the birch and fir and pine are confined to the Alps.

Agriculture. Italy is pre-eminently an agricultural country. Of its entire area 87 per cent. is returned as productive, the unproductive tracts embracing only the higher mountain districts and

the marshes; and even these latter are being gradually drained. Nearly half of the productive area is under cultivation. The official returns of the area under cultivation in the two periods of five years, 1870-74 and 1879-83, show an increase in the number of acres devoted to vines, olives, oranges, maize, oats, barley, rye, leguminous plants, and potatoes, and a decrease in the case of wheat, rice, chestnuts, hemp, and flax. As regards their yield, however, all the grain crops exhibit a falling off; and the decrease became still greater in the years 1884-89. The following table shows the average number of acres under the several grain crops, and the produce, for the period 1879-83; also the produce for 1894, which was similar to that for 1893:

	1879-83.		1894.
	Acres.	Bushels.	Bushels.
Wheat.....	10,951,340	128,200,294	117,830,000
Maize.....	4,675,399	82,000,057	57,800,000
Oats.....	1,099,051	18,269,002	16,500,000
Barley.....	856,552	10,891,154	8,068,000
Rye.....	396,894	5,054,417	4,273,000
Rice.....	496,685	20,142,258	15,770,000

The five-year mean of the wheat crop, which is higher than the yield of 1888, is equal to 11.7 bushels per acre, or not much more than a third of the produce per acre in Scotland. The produce of maize per acre, again, is about seven-eighths that of the United States. These crops do not meet the needs of the kingdom, and wheat figures as the heaviest item in the annual imports. In 1888-89 the quantity of this cereal imported increased by nearly 30 per cent., while the import of maize leaped from 2168 to 158,356 tons. The reduced wheat acreage is mainly due to the great increase of vineyards, especially in Southern Italy, and of meadow lands; the reduction would be greater but that a good deal of reclaimed land has been given up to this crop and to maize. Barley is largely used for feeding cattle, especially in the islands. As a rule it has a thick husk, and is of little use for beer; but of late years the government has made experiments in several provinces, and also distributed parcels of seed, with a view to promote the cultivation of a grain better suited for brewing. Rice, which is grown in very few places outside the northern plains, has in many districts been given up, partly owing to the competition of foreign rice, but largely because constant crops of it exhausted the soil. Haricot beans are a common crop in all parts of the country, as well as lentils and a smaller proportion of peas; but the crop of common beans, lupines, vetches, and the like, for winter forage, is twice as large. Lupines are raised also for marmite. Potatoes are grown everywhere, although the quantity is decreasing; and tomatoes and vegetables are also of importance. Of hemp (principally in Emilia and Campania) some 70,000 tons are annually produced, and of flax (a poor quality) 15,000 tons. Tobacco is grown mostly in the provinces of Lecce, Benevento, Vicenza, and Belluno. The crop varies from 5,000,000 to 10,000,000 lb. a year. The grape harvest in Italy is second in value to the cereals alone, and exceeds that of any one of them. The area under vines has been increased by about half since 1870, especially in Piedmont, Southern Italy, and the islands; and the government has established several schools of viticulture, besides expending considerable sums in defending the vines from the attacks of the phylloxera. Vineyards occupy some 7,650,000 acres, and the production of wine in 1887 was nearly 728 million gallons, or more than that of France (cf. Vol. IV. p. 774)—although in 1889, a bad year, the crop yielded only 465 million gallons. The Italian wines are still comparatively poor; but a fair quality is pro-

duced in Sicily and some other places where good methods are employed, and a considerable quantity of this is exported. Below the 44th parallel the olive is among the most valuable products. In Northern Italy it is of no importance, except in Liguria; and even there it is much less widely grown than formerly. Indeed, over all the kingdom the amount of olive-oil produced has greatly diminished: in 1879-83 the average for each year was nearly 74 million gallons, in 1888 less than 30 million gallons. For oranges, lemons, bergamots, &c., the returns show nearly 3000 million fruit, about two-thirds coming from Sicily. Much of this is exported, but part is used in the manufacture of essential oils, lime-juice, &c. Among the less important fruits of Italy are the fig, peach, apricot, prickly pear, and many others. Over 11 million acres are under forest. The almond, walnut, and hazel, the sumach, cork, and dwari palm, and much more the mulberry, are all of value. Finally, the chestnut is not only a prominent tree in the upland districts, but yields an important article of food; yet the use of cereals is gradually becoming more general, and on the lower hills chestnut-groves are giving place to vineyards. Still in an average year the harvest is over 700 million pounds.

The extent of cultivable land in Italy is being increased, both by deforesting and by the reclamation of land from the rivers and swamps. Cultivation is still carried on in a very primitive fashion in some parts, but in others machinery has for long been not uncommon, and generally modern methods are gaining ground. In Northern Italy, Tuscany, and round Naples, indeed, the farming is of a very high character. Double crops in the same year, as of beans after wheat, are often the rule, and it is not unusual to see olive-orchards where vines are planted beneath the trees and crops of some kind fill the space between the rows. Irrigation is more extensively employed every year; but the expense attending its use has helped to keep much of the land in the hands of large owners. Nevertheless, the system of peasant proprietorship is extending. Otherwise, land may be held by the metayer system, or by rent, paid either in money or in kind; or the cultivator may be simply the paid servant of the landlord, receiving a share of the produce for his labour. In any case, the life of the Italian peasant is, as a rule, one of unremitting drudgery and poverty—often of privation, and agricultural strikes have occurred, as in 1889 in the Gallarate district of Milan, and in 1890 at Concesio, in Romagna.

The crop of hay and grass in 1888 was over 21 million tons. Since 1880 there has been an almost constant increase in the area devoted to meadows and pastures; and this has been encouraged by the minister of Agriculture, both by means of prizes and by the distribution of seed. In 1890 there were 5,000,000 cattle, 6,900,000 sheep, 1,800,000 goats, and 1,800,000 swine. There are no returns of the number of buffaloes, but they probably amount to from 10,000 to 15,000. Northern Italy is famous for its dairy districts, and large co-operative dairies have been established, especially in Lombardy, in Veneto, and in the valley of Aosta. The well-known Parmesan cheese is manufactured from Lombardy to Emilia, Gorgonzola also in Lombardy, and Gruyere in Piedmont. There is a government experimental dairy at Lodi, which publishes reports. Butter and meat are exported, and also live cattle; but the exports of these last have diminished, seemingly owing to errors in breeding and feeding. This matter has received the serious attention of the government, and a Commissione Zootecnica (1887) has been appointed, and technical schools established throughout the country. Also, there

are over 200 royal stations for stallions; and the government aid to horse-breeding in 1888 exceeded £65,000.

Fisheries.—There are valuable fisheries round the coast and in the lagoons. The tunny is the most valuable fish, and after that the anchovy and sardine; but the eel-fisheries of Comacchio (q.v.) are also of importance. The *grande pesca* (i.e. fisheries carried on outside the boats' own districts or on foreign coasts) employed 1323 smacks, with 8796 men, in 1886; and of these 195 boats and 1072 men were engaged in the coral-fishery, and 45 boats and 856 men in the sponge-fishery. In 1888 the boats numbered 1421, the coral and sponge fisheries employing respectively 163 and 48. The principal fishing-grounds are off the coasts of Sicily, of Tunis, and of Istria and Dalmatia. Sponges are fished off Tunis, and coral now almost exclusively off Sicily—and even the Sicilian banks are rapidly becoming exhausted. In 1880 the discovery of a new bank at Sciaacea raised the total quantity fished there to 9,906,000 lb.; in 1888 it had fallen to 1,290,000 lb. In 1894 the total value of fish caught was about £6,800,000, and of coral raised nearly £90,000. The coral is sent across to the mainland in the rough state, and is worked chiefly at Torre del Greco, Naples, Leghorn, and Genoa.

Minerals.—Italy contains no deposits of bituminous coal, nor, except in a few localities, of iron. A very little anthracite and about 300,000 tons of lignite are raised annually, most of the latter in Tuscany and Umbria; and peat is found in many districts. Nearly all the iron is raised in Elba (q.v.), and a very little in Lombardy and Piedmont. The great mineral product of Italy is sulphur, which represents nearly half of the annual value of all minerals raised throughout the Kingdom; and of this nearly nine-tenths is obtained in Sicily. The total value of the mineral products decreased in 1882-94 from £2,952,610 to £2,150,000. In 1888 the principal items were sulphur, £1,000,500; zinc ores, £286,500; lead ores, £276,500; lignite, &c., £107,000; iron ores, £80,000; silver ores, £77,000; mercury, £68,000; copper ores, £65,000; boracic acid, £52,000; and gold ores, £19,500. The number of persons employed in this industry was 47,063 in 1887, 49,154 in 1888. In addition must be mentioned the quarrying of marble, granite, and alabaster, valued at nearly a million sterling annually, and employing some 20,000 men. The marble of Carrara (q.v.) is especially famous, as is also the alabaster of Volterra, near Pisa. See ALABASTER.

Manufactures.—Partly because of the high cost of fuel, Italy does not rank among the great manufacturing countries of Europe; but in some branches of trade her productions are of considerable importance. Owing to various causes, complete statistics are not in every case obtainable; but the great advance of the manufacturing industry generally may be estimated from the increase in the annual imports of coal, which increased nearly fivefold between 1871 and 1889. Still the steam-power machinery of the country, according to its relative horse-power, is equal to only about one-fortieth that of Great Britain, and is less than a third of that moved by water. Of principal importance is the silk industry, which employs some 150,000 persons, exclusive of those engaged in rearing the silk-worm; in 1889 this culture was carried on in 5188 communes, and by over 570,000 persons; the cocoon harvest amounted to 75,689,655 lb. (in 1888, to 96,798,272 lb.). The great seat of the silk industry is in Northern Italy, and especially in the province of Como. A large quantity of raw silk is still exported, to be returned in the form of textile goods. Nevertheless, the exports of silk in all forms greatly exceed the imports—in 1888 by

£9,400,000. The manufacture of thread and of cotton tissues shows a steady advance, as does also the spinning and weaving of wool. The manufacture of jute is confined to a few large factories. The north is the seat of the iron industry, but there is a large manufactory of iron rails at Terni, in Perugia; the principal copper-works are at Leghorn. The machinery manufactured, including that turned out by the government establishments, is valued at little short of £4,000,000 a year, the chief centres of this work being Turin and Milan; but machinery to the value of between one and two millions sterling is still imported annually. The manufactures of glass and ceramic wares are valued at £2,500,000; the former include the famous Venetian glass, and the latter majolica, faience (so called from Faenza), and other valuable wares. With these may be classed the cutting of carnos and the production of mosaics at Rome, Naples, and Florence, and also the working of coral. For the preparation of food-stuffs there are, according to the most recent returns available, 30,414 mills moved by water, steam, or wind (29,418 by water); besides these there are no less than 26,994 moved by animal power. The latter are chiefly for domestic purposes, however, and most of them are in Sardinia. About 6 million tons of corn and maize are ground annually, and nearly 90,000 persons are employed more or less regularly in the mills. Large quantities of flour-pastes are manufactured, principally from foreign wheat, which is harder than the native grain. Of spirits, made mostly from maize, the production in the fiscal year 1886-87 was 5,324,412 gallons; and to this must be added marsala, vermouth, and other liqueurs. In the same year there were 139 breweries in operation. Small quantities of sugar, glucose, and chicory also are produced; confectionery and preserved fruits are regular articles of export. The manufacture of tobacco is a government monopoly; in 1887 there were 17 factories, and two depôts (at Leghorn and Sampierdarena), employing 16,387 hands; the production amounted to nearly 40,000,000 lb. The output of the tanneries is estimated at £4,000,000, and there is a considerable export of gloves. There are numerous paper-mills in Piedmont, Lombardy, and Campania, and factories of straw-hats, the principal at Florence, and of cloth, silk, and felt hats in Piedmont especially. The export of straw-hats, though still considerable, is diminishing, while that of straw-plaiting is increasing. Sulphuric and tartaric acid, sulphate of quinine (made at Milan and Genoa), salt, soap, oils, candles, wax matches, &c. are also exported. Finally, the extensive building operations carried out within recent years with a view to modernise the large cities have given a great impulse to the manufacture of bricks and the like, as well as to the quarrying of stone.

Commerce.—The foreign trade of Italy is facilitated both by the extensive seaboard and good harbours and by railway connections with the countries beyond the Alps. In 1878 the kingdom was eighth in the list of European commercial nations, being surpassed by Great Britain, Germany, France, Holland, Belgium, Russia, and Austria; ten years later it had outdistanced Austria, and was about equal with Russia. The imports during these ten years showed a nearly steady increase, amounting finally to over 50 per cent.; the exports did not vary greatly, but on the whole exhibited a very slight falling off. The value of the former (excluding bullion and goods in transit) in 1887 was £61,030,000; of the latter, £39,955,000. In 1888 the imports fell to £46,584,000, the exports to £35,677,000; in 1889 the returns rose again to £55,627,000 and £38,019,000 respectively. Taking the entire trade of the country, one-fourth is set down to articles

of food, about a half to raw and partially-prepared materials, and the remainder to manufactured goods. Wheat represents an eighth of the total imports, and yarns and tissues nearly as much; after these come raw cotton, coal, timber, sugar, machinery, fish, iron, coffee, hides, cheese, tobacco, in this order. Silk, mostly raw or thrown, supplies about three-tenths of the exports, and wine more than one-tenth; olive-oil, fruit, eggs, hemp and flax, sulphur, worked coral, marble, and rice come next. The commercial intercourse of Italy up to the end of 1887 was chiefly with France (over 34 per cent. of the total); Great Britain (nearly 15 per cent.), Austria, Germany, Switzerland, and Russia following at some distance. In 1888, however, Italy entered on a war of tariffs with France, which had the immediate result of reducing the direct trade with the latter country by almost one-half, and Britain advanced to the first place. This change is in a large degree only apparent, for great quantities of Italian products, notably raw silk, have since been exported to Switzerland first, and thence to France. Nevertheless, its effect is to render the figures for the years that follow 1887 misleading. The principal imports from Britain are coal, iron, cottons and woollens, machinery, and sugar; the chief exports thither are olive-oil, oranges and lemons, with their essences and syrups, hemp, sulphur, chemicals, and marble. The Italian mercantile marine at the end of 1888 embraced 6810 sailing-vessels and steamers, with a tonnage of 853,033 tons; the steamers numbered 266, of 175,100 tons. Over nine-tenths of the whole were employed in the fishing and coasting trade. In the same year 111,257 vessels of 20,048,258 tons entered (111,103 cleared) Italian ports. The Italian shipping engaged in international navigation has rapidly fallen off of late years. More than half the steamers entering Italian ports are British, and these carry nearly four-fifths of the maritime trade. The most important seaports are Genoa and Savona, Leghorn, Naples, Venice, Messina, and Palermo. In 1894, of a total import of £43,000,000 (excluding specie) only £5,555,000 were from Britain; of an export of £10,000,000 £3,130,000 were sent to Britain. In 1894, 113,983 vessels of 28,200,000 tons cleared from Italian ports.

In 1895 there were 9300 miles of railway. Since 1885 the state lines have been worked by private companies, and about four-fifths of all the railways belong to two great systems, the Mediterranean and the Adriatic. Two notable tunnels, the Mont Cenis and St Gothard, connect the Italian system with those of France and Switzerland, and a Simplon tunnel is projected; there is also a coast line from Genoa to Nice, and several connections with the Austrian railways. There were also 1405 miles of steam tramways. In 1886 there were 50,101 miles of roads open, besides 7663 miles in construction; and the total length of navigable canals, mostly in Lombardy and Venice, was 655 miles. The rivers are navigable for about 790 miles. In 1881 there were 3420 post offices in Italy, in 1889 there were 4558; the surplus of revenue over expenses in the latter year was about £200,000. In 1889 there were 21,955 miles of telegraph lines, and telephones were to be found in sixty communes.

Social Conditions. The principal occupation, agriculture, employs nearly a third of the entire population, and the manufactures only about half as many. Nevertheless, the proportion of inhabitants congregated in cities is unusually large, and in Southern Italy and the islands even the peasants prefer to have their homes in some town or village. The sanitary condition of these towns, in which nearly three-fourths of the entire population is congregated, is often deplorable. A commission appointed in 1885 reported that in 6404 communes

there were no sewers of any sort, in 1313 there were sewers capable of carrying off rain-water alone, and in only 17,541 communes such as would carry off foul sewage; that in 3636 communes, with a total population of nearly 11,000,000, most of the houses had no privies, and in 1286 other communes, with a population of 2,762,000, this adjunct was lacking in almost every house; and that 1881 communes, with 9,500,000 inhabitants, were supplied with drinking-water of poor or bad quality, and 1495 others, with 6,000,000 inhabitants, did not receive water sufficient for the actual needs of the people. In such circumstances the prevalence of infectious diseases is not to be wondered at: in 1887 the proportion per million inhabitants of deaths from all causes in England and Wales was about two-thirds that of Italy, but from infectious and contagious diseases less than one-third. Yet in some respects an improvement is visible in the hygienic condition of Italy. The annual death-rate from malaria appears to be steadily diminishing, as does that from *pellagra*, a wretched disease resulting from insufficient and unwholesome food, and often ending in insanity; it is confined to the northern and central provinces. The proportion of deaths from alcoholism in the larger towns is much the same as that for all England, but for the whole of Italy it is only a third as great. The food of the artisan classes consists mainly of cereals and beans; maize is mostly used in the north, where also the small proportion of animal food is about double that consumed in the south. The diet of the peasantry, again, almost never includes meat or fish, and seldom any wine. Signor Bodio has calculated that the average daily wage overhead of work-people in factories, mines, &c. is about two lire (1s. 9d.); that of agricultural labourers, allowing for periods when their work is not required, he calculates at not much over one lira for every day in the year. The character of the people is in general sober and thrifty, and they prove excellent workmen where sheer labour is required, as in quarries and drainage operations; skill in the use of steam machinery, and the like, may be expected to develop with experience. Moreover, the old Roman spirit of stern utilitarianism is stronger in the sons of modern Italy than the æsthetic artistic temperament principally associated with them in many minds: the national type must rather be described as thoroughly practical; the 'improvements' that are transforming Rome, Florence, Naples, the miles of new streets, the staring blocks of modern houses, Paris-like, that have displaced the picturesque squalor of a generation ago, are sufficient evidence of this. Numbers of Italians migrate every year in search of work, and many who go abroad for longer periods still hope to return to their own land with a competence some day: in this respect the Italian love of country appears only less strong than the Chinese. The national character is passionate and quick to resent an injury, and the annual number of homicides per 100,000 of the population is nearly twenty times as great as in England; no other country of Europe, except Spain, approaches Italy in this respect. Capital punishment was definitely abolished in 1889. Assaults and wounding are also very numerous, and as regards all these offences against the person the southern provinces and the islands enjoy a grim pre-eminence. Yet a slight general decrease in the number of crimes and offences is observable within recent years. With regard to illegitimacy, Italy's position may be seen in the separate article on that subject; but here it should be noted that the percentage of illegitimate births has increased by more than half since 1863. The *ruota*, or foundling-wheel, is gradually being sup-

pressed: in 1866 it was in use in 1179 communes, in 1888 in 594 only, and these mostly in Sicily and the southern provinces.

Religion and Education.—Religious freedom is now secured to all creeds, but the Roman Catholic is the recognised state religion, and claims all but a very small fraction of the people. Of Protestants there are about 62,000, and of Jews 38,000; the former include some 22,000 Waldensians (q.v.). There are in Italy 51 Catholic archbishops and 223 bishops, and over 76,500 parish priests. The rank and dignity of the pope, as a sovereign prince, is recognised by the law of 1871 which defines the relations of the church and state; his person is sacred, his residence inviolable, and he has his own court in the Vatican (see ROMAN CATHOLIC CHURCH). Under a series of laws the great majority of the religious houses have been suppressed, small pensions being paid to most of their inmates who had taken vows, and their property confiscated. Part of the funds thus placed at the disposal of government have been devoted to educational purposes.

Education is under a minister of public instruction, who is assisted by a council; and in every province there is a school board, under the direction of the prefect. Nearly $1\frac{1}{2}$ million sterling, or about half the sum appropriated for this purpose in England and Wales, is set aside by the state annually for education; to this the communes and provinces add $2\frac{1}{2}$ millions. At the formation of the kingdom of Italy the general ignorance was incredibly profound, although learned societies existed in every large town, many of them, like the universities, of European fame (see ACADEMY). Reference to the separate article on illiteracy will show that, as regards education, Italy still comes behind most of the nations of Europe; yet notable progress has been made. In 1861, of those over nineteen years of age, 65 per cent. of the males and 81 per cent. of the females were unable to read or write; in 1881 the percentage had fallen to 54 for the males and 73 for the females. In 1866, of the men married 60 per cent. and of the women 79 per cent. had to make their mark; in 1888 the percentages were 42 and 62 respectively. The various parts of the kingdom differ widely in this respect. Piedmont has only 15 per cent. of conscripts and 11 per cent. of the men married illiterate, while in Calabria the respective percentages are 73 and 64, and in Basilicata 73 and 70. In all cases the proportion of women illiterate is greater than that of men. The notion of intellectual equality between the sexes is confined to a few earnest reformers, and there is much less adequate provision for the higher education of girls, although the universities nominally are open to women as well as men. The convent schools teach mainly embroidery and devotions, and the government and superior schools are not satisfactory. In 1861, however, a good high school for girls was opened at Milan, and its success has led to the establishment of many similar schools in other towns. Primary education is compulsory, and separate boys' and girls' schools are to be found in all but the very poorest communes. In 1861 '86 the number of pupils (male and female) in these elementary schools increased from 885,152 to 2,252,898; in 1886 there were 46,673 such schools open, besides 7553 private elementary schools. There were also 2139 asylums for children, many of them conducted on the kindergarten system, with 252,763 children; and there were 7444 night-schools with 283,230, and 5886 Sunday-schools with 169,609 pupils enrolled, besides 133 normal schools with 40,542 pupils. In 1888 the gymnasiums numbered 728 (255 episcopal and 441 private), with 49,980 scholars; the lycæums, 321 (124 episcopal and 55 private), with 13,688 pupils. Also, there were 481

technical schools and institutes (84 private), with 34,602 students; 23 mercantile marine schools (19 governmental), with 756 pupils; and 22 collegiate institutions and superior special schools, with 2662 students and 170 'hearers.' Finally, there are in Italy 21 universities, 17 of them governmental and 4 'free'—i.e. maintained by the provinces and communes; the total number of students and 'hearers' was 19,441 in 1893-94, besides 100 who were entered at three lycæums that provide a university course. The oldest university is that of Bologna (q.v.), the largest that of Naples (4104 students). The great body of Italian students are enrolled in the faculties of medicine and jurisprudence; theology is not taught in any of the universities. The students of divinity in the seminaries in 1881 numbered 11,277.

Government.—Italy is a constitutional monarchy, the executive power vested in the king, with succession in the male line, being exercised through responsible ministers. The legislative functions are in the hands of the king and parliament conjointly, the latter consisting of a senate and chamber of deputies. The number of deputies is 508; the franchise is extended to all citizens who are of age, can read and write, and pay 20 lire of direct taxes. The senate is composed entirely of life-members, with no fixed limit as to numbers (at present about 300); all its members, except the princes of the royal family, are nominated by the king, and must be forty years of age or upwards. Neither senators nor deputies are paid, but they have the right to travel free by rail or steamer in any part of Italy. Money bills must originate in the Lower House. The parliaments are quinquennial, but may be dissolved by the sovereign at any time. Ministers, who number eleven, are not necessarily members of either house. The government of the provinces, with a prefect at the head of each, is very much the same as in France.

Army and Navy.—Military (for the maritime population, naval) service is compulsory for all citizens from the age of twenty to thirty-nine, but only about 80,000 annually are drafted into the standing army (3000 into the navy). Recruits are divided into three classes, those of the third entering the territorial militia at once, and receiving unlimited leave, except, in time of peace, for 30 days' drill every four years. Recruits of the second category are enrolled for eight years in the permanent army (with unlimited leave) and four in the mobile militia (landwehr), and then enter the territorial militia. The infantry of the first category have, before being transferred to the territorial militia, three years with the colours, eight on leave, and four in the mobile militia; the other arms, nine years with the colours and on leave. One-year volunteers are admitted. The standing army in 1895 numbered 253,000 men, and those of the permanent army on unlimited leave 590,000; the total war strength, including mobile and territorial militia, was returned at about 2½ million men, about one million of whom had received a regular training. The carabinieri (21,000) perform the duties of gendarmes. There are a staff-college and a school for artillery and engineer officers at Turin, others for infantry and cavalry officers at Modena and Parma, for cavalry officers at Pinerolo, and for the sanitary corps at Florence, and military colleges at Milan, Florence, Rome, Naples, and Messina. A chain of fortresses has been erected along the northern frontier; there are numerous forts and batteries in the basin of the Po and along the coast; and Rome is protected by a circle of fifteen forts.

After the disastrous defeat at Lissa in 1866 the navy was reconstructed, and now, after years of unremitting exertion, Italy is one of the strongest

maritime powers of Europe. In 1876 the navy included 14 armoured, 7 unarmoured, and 2 despatch vessels, besides other vessels that brought the effective total to 53, with an armament of 298 guns; the thickest armour was 8½ inches. According to a report published in 1890, Italy had then 18 armoured battle-ships, 19 protected cruisers, 9 despatch-vessels, 6 torpedo cruisers, 1 sea-going torpedo boat, and 8 gun-vessels; the maximum thickness of armour carried by these vessels was 21½ inches, and their approximate value was put at 8½ millions sterling. There were also 128 torpedo boats, and other vessels that brought the total to 234 ships, representing with their armament a value of £15,000,000. Two of the armour-clads, the *Italia* and *Lepanto*, are the largest war-ships yet built, and the armament of the navy includes several guns of 100 and 106 tons. The period of service in the navy is eighteen years, but a limited number only of the conscripts actually serve four years, and the rest are normally on permanent leave. In 1888 there were about 17,500 officers and men on active service.

Finances.—The finances of Italy present an interesting study. From the first the young kingdom was burdened with the cost of the war with Austria and the debts of the old Italian states, and moreover has been obliged to face many years of extraordinary expenses; whilst the land, especially in the south, has never been developed to anything like its full capacity, and the revenue has been restricted in consequence. In 1862 there was a deficit of nearly £18,000,000, and it was not until 1875 that the first small surplus was obtained. Except the first half of 1884, the next ten years showed a surplus, larger or smaller; but each of the four years following 1885 ended in a deficit. Both income and expenditure have steadily increased: in 1862 the former was over £19,200,000, the latter £37,000,000; in the financial year 1888-89 the actual revenue was £60,034,000, the expenditure £69,409,000—deficit, £9,375,000. The chief sources of income are the customs, the income, land, and house taxes, and the tobacco monopoly; the principal expenses are the interest of the public debt, exceeding 21 millions sterling, and the cost of the army and navy, which is nearly as great. In proportion to the productivity of the country, Italy's public debt is very heavy. At the end of 1861 it was slightly over £125,000,000; but a long succession of annual deficits, extensive railway and other public works, and costly armaments have raised it year by year till in 1895 (when the revenue and expenditure were about £70,000,000) the debt had reached £492,344,300, amounting to £15, 18s. 5d. per head of the population, exclusive of the communal and provincial debts. Meanwhile it should be noted that the Italian government has removed certain of the old, objectionable imposts, such as the grist tax; and in 1883 the forced paper currency was withdrawn from circulation.

For information as to Italy the best sources are the admirable official publications, a complete list of which is included in the *Saggio di Bibliografia statistica Italiana* (3d ed. Rome, 1890). The *Annuario statistico Italiano* (published since 1878) contains topographical as well as statistical information; most of the statistical portion will be found summarised in the *Statistica's Year-book*. A comprehensive review of Italy's progress is presented in a memoir, equally able and candid, *Di alcuni Indici del Progresso economico e sociale d'Italia* (Rome, 1890), by Signor L. Iodio, one of the most masterly of present-day statisticians. The *Dizionario geografico* (8 vols.), by Amati, is part of a monumental work in course of publication at Milan (*L'Italia sotto l'Aspetto fisico, storico, artistico, e statistico*). See also Laveleye, *L'Italia attuale* (Paris, 1881), and, among English works, Gallenga's two books on Piedmont, his *Italy Revisited* (2 vols. 1875),

and *Italy Present and Future* (2 vols. 1887); the books of A. J. C. Hare (q.v.); and Beauclerk's *Rural Italy* (1888). For Southern Italy, see Lenormant, *La Grande Grèce* (3 vols. 1881-84) and *A travers l'Apulie et la Lucanie* (2 vols. 1883); and Mrs Ross, *The Land of Manfred* (1889).

HISTORY.—The ancient history of Italy will be more conveniently treated of under **ROME**; see also **ETRURIA**, **UMBRIA**, &c. In 476 A.D. the Herulian mercenaries in the pay of the western empire rose in revolt, and proclaimed their leader Odoacer king; and the last emperor of the West, the pretty boy Romulus Augustulus, was sent to end his days amid the woods and fish-ponds of Lucullus' villa near Naples. The senate, by Odoacer's command, recognised Zeno as head of the western as well as the eastern empire, and he in turn bestowed on the Teuton leader the dignity of 'patrician.' For thirteen years Odoacer's rule was undisputed; but in 489 Theodoric, king of the Ostrogoths, invaded Italy with a commission from the Greek emperor, besieged the Herulian in Ravenna, and in 493, after his surrender, slew him with his own hand. In spite of this bloody beginning, Theodoric's rule, which lasted till 525, was wise and, on the whole, just. But the Arian faith of the conquerors held them and the Italians apart, and when Justinian's general Belisarius was sent to reconquer Italy he was welcomed by the colonists of Sicily and the south. From 536 to 553 the war was desperately maintained, the hero on the Gothic side being Totila (541-552). But the valour of the barbarians was outmatched by the generalship of the aged eunuch Narses; and in 553 Teias, the last king of the Goths, was slain in battle, and the descendants of the host who had followed the Amal king into Italy sixty-four years before, now few in number and sore at heart, were permitted to march back across the Alps. Italy was now governed from Ravenna for a few years by an exarch or viceroy; but in 568 came an invasion by the Lombard nation, under their king, Alboin, and all the central portion of the peninsula passed from under the sway of Byzantium. Pavia was made the capital of the new kingdom, and the great duchies of Spoleto and Benevento were founded, pressing on Rome and the Greek maritime cities of the south. Yet the Lombards were not strong enough to occupy the whole peninsula, and Rome and most of the coast towns, as well as the islands, remained to the emperor. The invaders imposed on the country a sort of feudal system, and, being Arians, treated the Italians with great harshness, until Gregory the Great effected their conversion to orthodoxy. From this period the popes for a time appear as the champions of the national cause. Leo the Isaurian's decree against the worship of images was met by Gregory II's declaration of Roman independence; and in 726-56 the popes succeeded in driving out the exarch and checking, with the help of the Franks, the encroachments of the Lombards. Pepin twice crossed the Alps, compelled the Lombard king to yield up the exarchate and the Pentapolis, which he had conquered, and presented them to the pope in 756; this gift was the nucleus of the temporal sovereignty of the bishops of Rome.

In 774 Pepin's son, Charlemagne, who had been summoned to the aid of the pope, deposed Desiderius, the last Lombard king, and added his dominions to his own; in 800 he was crowned emperor of the Romans. Meanwhile the Lombard duchies in the south were still independent, and Sicily and a number of free cities in Southern Italy, as well as Venice, recognised the Greek overlordship. But in the 9th century the Saracens subdued Sicily, landed on the mainland, and even threatened Rome. Leo IV. fortified the suburb on the

north bank of the Tiber, which after him was called the Leonine city, and called to his aid Louis II., Charlemagne's great-grandson, who, with the help of the eastern emperor, checked the progress of the Saracens for a time. But after the death of Louis the infidels compelled the helpless pope to pay tribute; and the Greeks, profiting by the weakness of Charlemagne's successors, recovered most of Southern Italy, and held it, under an officer entitled Catapan, till 1043. Eight kings of the Carolingian line were acknowledged in Northern Italy, their rule ending with Charles the Fat in 887. Then, till 961, succeeded ten so-called Italian sovereigns—dukes of Spoleto and Friuli, the German Arnulf, Hugh of Provence, Berengar, marquis of Ivrea, and others. Under their feeble sway the power of the feudal nobles, and, within the cities, of the bishops, waxed great, the papal chair was occupied by men of infamous life, and Magyars, Saracens, and Northmen overran the country, turning wide tracts into a desolate wilderness. In 951 Berengar II. was compelled to do homage to the German king, Otto of Saxony. He was suffered to rule until 961, and then deposed; and in 962 Otto was crowned as king of Italy at Milan and as emperor at Rome. From this time the right to the crown of the Roman empire (two centuries later it was the Holy Roman empire) was held to accompany the German kingship. Except in name, there was no longer an Italian kingdom, and, with its foreign emperors occupied for the most part beyond the Alps, the country was in some degree left masterless. Its division into separate states was now but a question of time.

Moved by the scandals of the papacy and the constant revolts in the city, Otto took the election of the popes away from the Romans, chose a pope of his own, and put the city in his charge. Elsewhere he encouraged the rise of the communes as a check upon the great vassals. The towns had already been permitted to raise walls as a defence against the barbarians, and now the chief cities were freed from the jurisdiction of the counts. The death of Otto III. in 1002 was followed by a dispute for the crown; Rome, the papacy and the city, fell again into the hands of the Tuscan counts, while the Lombard cities gained in importance as their alliance was sought by one side or the other. Milan supported Henry of Bavaria, who had been elected in Germany; and he severely punished her rival Pavia, who had espoused the cause of the Lombard Ardoin. Henry died in 1024, and was succeeded by Conrad of Franconia, who was invited into Italy and crowned with the iron crown at Milan, by Heribert, the archbishop. Under this prelate Milan advanced greatly in power and independence. An effective militia was formed, and Heribert is said to have invented the *carroccio*, a car which carried into battle the city's banner and an altar, and round which the burghers fought as in defence of a sacred thing. The citizens had already formed themselves into a *parlamento*, and, while Heribert lived, the power of the smaller counts who had now come to dwell in the city was brilled. The other Lombard cities also were rising into some degree of independence. Pisa and Genoa, besides Venice (which acknowledged the nominal sovereignty of the Greek emperor), were becoming great by their command of fleets; and they succeeded to the rich carrying trade of the Mediterranean after the fall of the Greek cities in the south before the Normans. During the first half of the 11th century a body of Norman adventurers had gained a firm footing in Apulia, which they ultimately conquered as a county for themselves. The pope, Leo IX., marched against them, and was defeated and taken prisoner by Robert Wiscard or Guiscard at Civitella (1053);

and Wiskard obtained from him the investiture of his present and future conquests, which he was to hold as a fief of the holy see. Robert extended his power on the mainland, and took the title of Duke of Apulia and Calabria in 1059. In 1060-90 his brother Roger conquered Sicily from the Saracens; in 1127 the family's dominions in Apulia, Calabria, and Sicily were united by his son Roger, who in 1130 assumed the title of king of Sicily.

Meanwhile the fierce struggle over Investitures (q.v.) had been fought out between emperor and pope. When the archdeacon Hildebrand became Pope Gregory VII. he enforced the celibacy of the clergy, as Leo IX. had already endeavoured to do; and in 1075 he condemned the investiture of ecclesiasties by lay lords. Otto the Great and Henry III. had appointed and deposed popes, and therefore this latter decree led to a quarrel with Henry IV. (q.v.). At a diet in 1076 Gregory was deposed. The pope replied by excommunicating the king, who was compelled by a rebellion in Saxony to submit and do penance at Canossa, the castle of the Countess Matilda of Tuscany, the pope's ally. Henry, however, soon renewed the strife, appointed an antipope, and in 1084 took Rome, was crowned, and besieged Gregory in the fortress of St Angelo. Thence the pontiff was delivered by Wiskard, who drove the emperor off, and carried Gregory away from his riotous subjects to end his days at Salerno. The struggle, however, was carried on by Gregory's successors, till by the concordat of Worms (1122) the emperor yielded the main principle at issue, surrendering to the cardinals the election of the pope, who was still to possess the right of conferring the imperial crown. By the death of the Countess Matilda, too, in 1155, the church had inherited her vast domains; and, although the emperor took possession of them, the popes retained their claim, to be revived in after years.

From this long struggle the northern cities emerged strengthened and practically autonomous. They still belonged to the empire; but they were governed by their own magistrates, called consuls, aided by an oligarchical council; and they enjoyed, and unhappily took frequent advantage of, the right to make war on their own account. The quarrel of the Guelphs and Ghibellines (q.v.) arose in Germany at this time, and before long these names were heard everywhere in Italy; but here they stood not alone for the pope's party and the emperor's, but also for the burning jealousy and hatred of rival cities, each struggling to rise at the cost of its neighbours. Arnold of Brescia (q.v.) for a time established a republic in Rome, but it was suppressed by Frederick Barbarossa in 1154. In that year Frederick, who had been elected king in 1152, came into Italy to take away the self-government of the towns, and reduce them to their former subjection to the emperor. After punishing several hostile cities, he went on to Rome and was crowned by Adrian IV. (Nicholas Breakspear), the only pope of English birth; but he soon quarrelled with him, and on Adrian's death supported an antipope. In 1158 Frederick returned from Germany, and compelled Milan to surrender, after a month's siege. He now set in every town a podestà to administer justice, who should be chosen always from another city; and from cities and barons alike he took away the privilege of making war on one another without his permission. An attempt to appoint their consuls also drove the Milanese into a second revolt, in 1159; but Frederick was delayed by the heroic defence of Crema, and it was not till May 1161 that he again invested Milan. The city held out till March 1162, and was then destroyed by the vindictive imperialists, and the people driven from the ruins.

Soon afterwards the cities of the Veronese march formed a league of defence against Frederick which he was unable to crush. In 1167 he besieged the pope, Alexander III., in the Coliseum; but the latter escaped to Benevento, while a terrible pestilence fell upon the German camp, and Frederick with difficulty led the remnant of his army north to Pavia. Only this city and the Marquis of Montferrat in all North Italy had held back from the great Lombard league, which had meanwhile been formed and had restored the Milanese to their city. In 1168 Frederick fled in disguise across the Alps; and in the same year the confederates founded a new city on the plain between Pavia and Montferrat, to be a check on these two. The league named it Alessandria, in honour of their ally the pope: *della paglia* ('of straw'), their enemies added in derision; but its ditch and rampart of earth held Frederick at bay all through the winter of 1174-75, till he was forced to raise the siege. Finally, the crushing defeat at Legnano (May 29, 1176), from which field he hardly escaped with his life, made him willing to treat for peace. In 1177, at Venice, the emperor came to terms with the pope, and agreed to a six years' truce with the Lombard towns; in 1183 a permanent peace was ratified, the cities retaining their right of war and of self-government, and the emperor his podestàs and his rights of sustenance and support against enemies outside the league. The rule of podestàs was soon adopted outside of Lombardy as well, for the settlement of nobles in the towns had introduced a lawless element and given rise to factions; so that a supreme judge who was not a townsman, who held office for a single year, and had then to render an account of his administration, was most likely to prove impartial. Yet from the podestàs to the despots was but a step, and this was taken a few years later.

Since the battle of Civitella the Normans had continued faithful allies of the popes, and it was with the object of depriving the latter of this powerful support that Frederick now had his son Henry VI. married to the heiress of Sicily. Frederick died in 1190, and in 1194 Henry was recognised as king, and the Norman rule in Southern Italy came to an end. He died in 1197, and the next year his wife, who had acknowledged the pope as overlord, died also, leaving their infant son Frederick to the guardianship of Innocent III. The papal territory had now become extensive, and the establishment of a Latin empire at Constantinople (1204), during the fourth crusade, added to the prestige of the Roman see. But the chief gainer by the capture of the eastern capital was Venice, who, as a reward for lending her fleet, was presented by the victorious crusaders with a large share of the divided empire, and was able to occupy at least a number of islands and coast territory; she was now supreme in the Levant. Frederick II., who was crowned emperor in 1220, was king of Italy, Sicily, Sardinia, Germany, Burgundy, and Jerusalem. So formidable a prince made popes and communes both uneasy. He was excommunicated by Gregory IX. in 1227, because he delayed his departure on a promised crusade; and afterwards, when he had gone to the East, while he was crowning himself at Jerusalem his enemies were still busy at home. The pope, whose hands were greatly strengthened by the newly founded Franciscan and Dominican orders, stirred up the Lombard cities to revolt, and, after Frederick had crushed the Milanese at Cortenuova (1237), drew Venice and Genoa into the league against him. Frederick's cause was upheld in Northern Italy by Ezzolino da Romano, infamous for his cruelties. In 1245 Innocent IV., the emperor's personal

enemy, had him declared dethroned by a council convened at Lyons; and after five years of harassing anxiety, his life the object of constant plots, Frederick died in December 1250. The cause of his son and grandson was upheld by his natural son Manfred, who in 1258 became king of Sicily. There was no abatement of fury in the fierce struggle between Guelphs and Ghibellines, but the balance of success so far inclined towards Manfred after the battle of Montepertoso (1260), which restored Florence to the Ghibellines, that Urban IV. invited Charles of Anjou into Italy to head the Guelphic party. In 1266 Manfred was defeated and slain, and the Swabian line came to an end with his nephew Conradin, who was beheaded at Naples. The Guelphs were again supreme; but Gregory X. restored their banished rivals to their cities, and for a time made the two parties live in peace. Charles, who received the kingdom of Sicily as the gift of the popes, had promised that it should never be held along with the empire; and now, as a final check to the Angevin's possible ambition, the pope brought the dispute to a close which had kept the empire without a head, and crowned Rudolf of Hapsburg, who was elected in 1273. This emperor in 1278 recognised the popes as temporal sovereigns, and their power was henceforth firmly established over Rome and the Campagna, Emilia, the Romagna, and the March of Ancona; and, as Rudolf left Italy to itself, the Guelphic party was enabled to strengthen its power and to crush such hostile cities as Pisa. Charles lost Sicily by the rebellion which began in the Sicilian Vespers (q.v.), in 1282; and the island gave itself to the House of Aragon, which, as the popes were hostile, necessarily became Ghibelline. Meanwhile, in Tuscany the triumphant Guelphs had become broken up into factions, the Neri and Bianchi (Blacks and Whites), the former violent Guelphs, and the latter at first moderate Guelphs, until the fierce animosity of their opponents made them Ghibellines. For in 1301 Charles of Valois, who had been called in by Boniface VIII. to help the Neri, entered Florence, and gave the Bianchi up to the cruel vengeance of their enemies; among those banished from the city was the poet Dante. Under Clement V. the seat of the papacy was removed, in 1309, to Avignon, where it remained for the next seventy years. In the following year the new emperor, Henry VII., came into Italy to revive the Ghibelline party, and to restore peace and order. The task, however, was now beyond the power of any German master. Henry died in August 1313, having effected no lasting change except in Milan, which he had handed over to the Ghibelline Visconti.

We have now reached a period when the cities of Northern Italy had fallen under the sway of tyrants or despots. The feudal power of the rural counts had gradually been lessened by the communes, until the nobles had become citizens. But they merely exchanged their castles for fortified palaces in the cities; and, although the podesta had curbed their power for a time, his office eventually became not so much that of a dictator as of a judge, and the interminable wars had tended to give the nobles an undue predominance, since, being trained to arms, their military skill naturally placed them above the burghers. In some towns, such as Florence, where the democratic spirit was strongest, they were kept in check by a *gonfaloniere of justice*; but in most cities the *captain of the people*, who represented the party in the ascendant, and in these war-times was of course a noble, gradually raised himself to the position of master. It was then his aim to depress the others of his own order, both to win popularity with the people and to prevent possible rivalry. At the root

of the wars fought between those in Italy who called themselves Guelphs and Ghibellines was the question whether the democracy or the aristocracy was to be supreme in the cities. Florence as yet preserved her republican independence; but, besides a hereditary oligarchy in Venice, despots were now established in all the great northern cities, each of which was glad to submit to a master who would put an end to the strife that had hampered its commercial prosperity. Titles were bought from the German emperors or assumed, courts were formed, and armies were hired; for wars were now waged in another fashion than that which had prevailed in Barbarossa's time. Then it was an honoured custom for the artisans and traders of a city to devote a week or a month in the year to harrying the fields of a rival commune, to draw its defenders into an ambushade, or even to capture and ruin the town, provided it did not hold out too long; in any case, the citizen-soldiers returned home in a few days, and took up their ordinary work again. Now, however, war was a science and soldiering a trade; the iron panoply and ponderous lance of the man-at-arms were not for the craftsman or the clerk. Therefore, in the 14th century, bands of mercenaries, or companies of adventure, under condottieri, made their appearance, selling their services to the highest bidder, or plundering the lands of the weaker states. Their battles were almost bloodless, the campaigns indecisive. Bound by a common profession, they were chiefly formidable to the taxpayer; and, for that matter, in their commercial prosperity the cities were at this time receiving the reward for which they had bartered their independence. If we glance at England in this period, which followed hard on Bannockburn, we find commerce and manufactures still in their infancy, wool the staple export, houses of mud in the streets of the cities, and rushes strewn in the king's chamber; but the nation had now its constitution complete, and was moving in the broadening path of freedom. The condition of Italy was in sharp contrast to all this. Trade and manufactures were flourishing, art and literature were encouraged at the courts, and freedom was forgotten in present comfort and inglorious well-being. The result of the self-indulgent policy now begun was seen two centuries later, when Italy lay helpless beneath the feet of contending foreign armies.

The 14th and 15th centuries witnessed the division of Italy among five principal powers—the kingdom of Naples, the duchy of Milan, the republics of Florence and Venice, and the papacy. In Naples the Angevin line came to an end in 1435 with Joan II. She was succeeded by Alfonso V. of Aragon, and the Two Sicilies, separate since 1282, were again united. At his death in 1458, however, Sicily remained to the kings of Aragon, while Naples was bequeathed to his natural son. In Milan the powerful Visconti dynasty survived till 1447. Archbishop Gian Visconti, who died in 1354, made himself master of more than twenty cities, and extended the family's power over the greater part of Northern Italy; and these domains were reunited by his grand-nephew, Gian Galeazzo, who purchased the title of duke, made himself lord as far as the borders of Venice, and was threatening Florence when the plague carried him off in 1402. The Visconti's possessions were confined within narrower limits under his son Filippo, and were seized in 1450 by Francesco Sforza, a famous general, who had married Filippo's natural daughter, and who proved a wise and able ruler. Florence had submitted in 1342 to a despot in Walter of Brienne, the titular Duke of Athens; but this soldier of fortune was expelled in 1343, and the city was ruled until 1434, except during a brief

revolution, by an oligarchy. The presidency of the republic—practically the dictatorship—was then secured by Cosimo de' Medici, who for this end had courted the good-will of the common people; and his undefined power passed at his death in 1464 to his son, and reached its culmination under his famous grandson, Lorenzo the Magnificent. Florence was already mistress of great part of Tuscany, and Cosimo's alliance with Francesco Sforza helped to secure her position as one of the five great powers. Venice, which had until this period stood aloof from Italian politics, was in the hands of a hereditary grand council. Thirty years of contest with Genoa for supremacy in the Mediterranean had ended in victory for the republic of St Mark in 1381. The capture of Constantinople by the Turks in 1453 made Venice, who had been gradually stripped of her possessions in the Levant, now at last an Italian state; and her territory on the mainland was greatly extended under Francesco Foscari (1457) and his successors in the dogeship, although in 1477 a Turkish army ravaged her fields to within sight of St Mark's. Rome, except during Rienzi's brief rule, had obeyed her bishops, exiled at Avignon. In 1377 the papacy returned from the Babylonish captivity, and, in spite of the weakness caused by the Great Schism, the spiritual sovereign also was soon found among the despots. The schism ended in 1449, and Nicholas V. was enabled to establish firmly the temporal power of the papacy.

Italy now enjoyed a term of prosperity and comparative peace, broken only as Venice enlarged her borders, or by the family ambitions of the popes. But in 1494 Charles VIII. of France was induced by the Milanese regent, Lodovico Sforza, to invade Italy, and had himself crowned king of Naples. Meanwhile, Lodovico had murdered and succeeded his nephew, and he now raised Lombardy against Charles, who with difficulty got back to France in 1495. He had caused the expulsion of the Medici, and Florence was again a republic, in which for a time Savonarola's influence was all-powerful. But, of more consequence than this, Charles's expedition had shown the way to others, and inspired an ambition which, under his immediate successors, cost France dear. In 1499 Louis XII. subdued Milan; in 1501 Ferdinand the Catholic tricked him out of Naples, which the two had joined to conquer, and once more united the Two Sicilies under one crown.

The century thus begun is the most disastrous in Italian history. In Northern and Central Italy the French armies held their own against the pope and his allies until the year 1512, when their young general, Gaston de Foix, fell in victory before the walls of Ravenna. They were then expelled for the moment; but Italy had no long rest. The rivalry of the Emperor Charles V. and Francis I., which makes the principal part of European history during this period, filled the land with the clash of foreign arms; while her own rulers, striving each to snatch an advantage from the confusion, added to the country's distractions. The papacy was a gainer from the struggle. The conquests of the Borgias passed to the holy see; and Julius II. succeeded in humbling Venice, and then in driving the French out of Lombardy in 1512. In 1515 Francis regained Milan, but in 1521 his forces were expelled from Italy by the emperor, and in 1525 the French king was taken prisoner at Pavia. In 1527 occurred the sack of Rome by a body of troops of the empire, Lutherans and Spaniards. The Constable de Bourbon, who had led them, was killed in the assault, and the sack continued for seven dreadful months. In September the Medicean Clement VII., who had fled to the castle of St Angelo, was compelled by hunger to surrender.

The Medici, who had returned to Florence in 1512, were again driven out, but were restored by arms in 1530. Alexander de' Medici received from the emperor, who was his father-in-law, the title of duke; and in 1570 Cosimo, his successor, was made Grand-duke of Tuscany by the pope. By the peace of Cambrai (1529) Charles had been left master of Italy; his son Philip became its undisputed lord by the peace of Cateau-Cambresis (1559), though Venice really, and Genoa, Lucca, and the little republic of San Marino nominally, remained independent. Besides Tuscany, there were the duchies of Modena and Ferrara and of Parma and Piacenza, and the rich States of the Church; Spain herself held all the rest of Italy, save Piedmont, which was restored to the dukes of Savoy in the person of Philip's cousin and general, Emmanuel Filibert. This prince also regained Savoy and the province of Nice, which his family had lost; but he removed his capital to Turin, and his house was henceforth Italian. The papacy had been strengthened by the founding of the Jesuit order in 1540, and the establishment of the Inquisition; and the Council of Trent (1545-63) defined the Catholic faith. The territory of the church was further augmented by the absorption of several lapsed fiefs, and the supremacy of the pontiffs was now acknowledged by Venice, who had hitherto recognised no superior to her own patriarch. But Venice was no longer the great state she had been. Her commerce had fallen off since the discoveries of Columbus and Da Gama, and most of her conquests were in the hands of the Turks, to whom, in spite of the victory of the allied fleet at Lepanto (1571), she had been compelled to give up even Cyprus. Her last great achievement, in a war that she had waged at intervals for five centuries, was the conquest of the entire Peloponnesus, in 1684; but in 1715 this fell again into the hands of the infidels. The power of Spain, too, had greatly declined, and besides Masaniello's revolt at Naples (1647) there were risings in Sicily, which gave the island to Louis XIV. for two years. But throughout this period, and until as late as the 19th century, Italy was disposed of by foreign powers, and partitioned as suited their policy. After each of the three European wars of succession, in the 18th century, Italy was subjected to a fresh re-division; but it is not necessary to notice more than the last of these in detail. The services rendered by the House of Savoy against the French, during the war of the Spanish succession, won for it the island of Sicily and the title of king. The new monarch, Victor Amadeus II., was one of the liberal and enlightened despots of the time; and although in 1720 he was compelled to exchange Sicily for Sardinia, from which island his successors took their title until 1861, he built up a real kingdom, took the schools away from the Jesuits, and did much to promote the welfare of his subjects. The last war, that of the Austrian succession, in which the Sardinians fought gallantly on the Hapsburg-Lorraine side, ended with the treaty of Aix-la-Chapelle (1748), which left Italy divided as follows: the House of Savoy held Sardinia and Piedmont, with Montserrat and Alessandria, Tortona and Novara; the Austrians retained Milan and Tuscany; the Bourbon Charles III. was king of the Two Sicilies, and his brother Philip, Duke of Parma; the papal territory stretched across the centre of the peninsula to the frontiers of Venice, which survived as a republic until 1797; and finally, Modena and Genoa were placed under the protection of France, to whom the Genoese ceded the island of Corsica in 1755. Italy now enjoyed a brief period of freedom from wars; but her numerous sovereigns were absolute, each within his petty domain, and the despotic policy of

the Bourbons, who held nearly all the country, was generally adopted. An honourable exception was Peter Leopold, who was Grand-duke of Tuscany from 1765 until he succeeded to the Austrian empire as Leopold II. in 1790. He instituted many reforms, restricted the power of the priesthood, and suppressed the Inquisition; and to him is owing the reclamation of the fruitful Val di Chiana from a wilderness of pestilent marsh. To the rule of this prince the harsh, jealous oppression of the other sovereigns presents a pitiful contrast. For Italy the long reign of misery and darkness was at last about to pass away—but slowly; the night was not yet past.

The storm of the French Revolution burst in 1792. In 1796 Napoleon entered Italy; in 1797 the Cisalpine, Ligurian, Cispadane, and Tiberine republics, with their capitals at Milan, Genoa, Bologna, and Rome, were formed out of Northern and Central Italy, and Venice and her territory beyond the Adige were bestowed on Austria. The next year Naples surrendered, and was made the capital of the Parthenopean Republic. The democrats in the cities joyfully welcomed the new doctrines brought by the invading army; but even they soon wearied of a nominal freedom that bestowed chiefly the privilege of sharing the heavy costs of the French wars, and in 1800 Napoleon had to win the peninsula afresh by the victory of Marengo. In 1804 he made himself emperor, and in 1805 he was crowned king of Italy at Milan. The Bourbons were permitted to retain Tuscany and Naples, and the pope was reinstated in the possession of Rome. Naples, however, was given to Joseph Bonaparte in 1806, and to Joachim Murat in 1808; in 1809 Rome was annexed to the French empire, and the emperor's sister Eliza was made Duchess of Tuscany. The Congress of Vienna (1815) restored the map of Italy very much to its former appearance; but the advantages of the new distribution fell nearly all to the House of Austria. Venice was added to the Austrian crown, and Lombardy retained; an Austrian duke was set over Modena; and the Austrian Ferdinand III. received back Tuscany, to which Lucca was to be added whenever the death of Napoleon's Austrian wife, Maria Louisa, should give Parma again to its former Bourbon masters. The only other lasting change was the transference of Genoa to Victor Emmanuel I. of Sardinia. Naples and Sicily were restored to the Bourbons, and the pope was once more put in possession of the States of the Church. The little republic of San Marino was also recognised by the congress.

A period of absolutism and rigid repression now ensued. The returned princes adopted in full the policy dictated from Vienna, and strove by all means to crush the rising spirit of independence. The Jesuits, whose order had been suppressed by the pope in 1773, were restored and the elementary education placed in their hands, where it was effectually strangled. The legions of Austria filled Lombard-Venetia, and were at the service of all the petty despots in the other parts of Italy; while a yet larger army of spies was at work in every corner of the unhappy country. The general misery provoked conspiracy, and the revolutionary Carbonari societies sprung up everywhere. But the movement had as yet no directing head. There were risings in Southern Italy in 1820, but they were suppressed in the following year, and the leaders executed; and numerous less important insurrections there, in the period preceding 1846, were easily put down. Other abortive attempts were made in Piedmont, in Lombardy, in Modena and the Romagna, the only result of which was to make the rulers' hands yet heavier on the people. Nor was there thorough unanimity or common

action among Italian liberals. The extreme republicans, represented by the party of Young Italy, were headed by Mazzini, whose fiery eloquence and enthusiasm transformed the vague desires of his countrymen into a passionate hope; but his policy sanctioned methods from which more sober patriots shrank. From Geneva he led a band of refugees to the invasion of Savoy, in 1833, because the new king, Charles Albert, would not enter on a war with Austria; but this wild raid proved an utter failure. Already the wiser minds in Italy looked to Sardinia for deliverance; but the dream of a confederacy, with perhaps the pope as president, was not yet dispelled. Nay, it seemed about to be realised when, in 1846, Pius IX. assumed the tiara, and initiated a series of liberal reforms. Constitutions were granted in 1847 by all the rulers save Austria and Ferdinand II. of Naples; and from the latter a constitution was wrung in the following year. The year of revolutions, 1848, opened with a street massacre by the Austrians in Milan, on 2d January. In February the French Republic was declared, and then in Italy the party of Mazzini was for a moment supreme. Sicily revolted from Ferdinand, and in March Charles Albert declared war on the Austrians, who had been driven out of Milan and Venice. He passed the Ticino, and defeated Radetsky at Goito; but on 25th July the Austrians won the decisive battle of Custoza, re-entered Milan, and placed the country under martial law. In Naples there had been a massacre in May, and on 30th August Messina was bombarded. Meanwhile the pope's heart had failed him. His troops had gone to the help of the Sardinians, but before their surrender he had declared their advance to have been without his leave. The republicans, who had regarded his liberal measures with suspicion and jealousy, now denounced him as a traitor to the cause of Italian freedom. On 15th November his wisest minister, Count Rossi, was assassinated, and Pius fled to Gaeta in disguise. A republic was set up in Rome on 9th February 1849, under Mazzini and two other triumvirs. The Grand-duke Leopold had fled from Florence, but Tuscany refused to join herself to the republic; yet when the sovereign she had invited back returned, his first act, supported by the presence of Austrian troops, was to suppress the constitution. In Piedmont the ultra-radicals, headed by Rattazzi, were now in power, and a fresh campaign against Austria was begun—this time lasting less than four days. On 23d March Radetsky defeated the Piedmontese at Novara. Charles Albert gave up his throne to his son, Victor Emmanuel II., and died, broken-hearted, at Oporto four months later. Efforts were now made to reduce Rome and Venice. In vain did Garibaldi, who had been called to the defence of Rome, defeat the Neapolitans at Palestina and Velletri. A French army, under General Oudinot, took the city, after a four weeks' siege, on 2d July. Venice, under the heroic Daniel Manin, bravely kept her enemies at bay until 22d August. The petty sovereigns now came back—the pope last, in April 1850. Rome, occupied by a French garrison, was kept in a state of siege for seven years, and the city never quite recovered its freedom until 1870. Italy's first general effort for freedom had ended in failure: 1848 was a year of unfulfilled visions. But one important gain was effected: the dream of federation was ended, and all men looked now to the House of Savoy, save the few idealists, like Mazzini, who afterwards stood sternly apart from the triumph of compromise.

Victor Emmanuel was faithful to the Italian cause, and persevered in the path of reform on which his family had entered. Sardinia was relieved, by the law which gave the government

power to abolish monasteries, from the incubus of an army of idle and ignorant ecclesiastics; a liberal constitution was in force, the press was free, education was spreading, and a measure of religious liberty was enjoyed. In 1853 the Sardinian prime ministry passed into the hands of Cavour, the brain, as Garibaldi was the arm, of the coming struggle. Henceforth he inspired and guided the national movement, until his death in the moment of victory. The Sardinian troops, reorganised by La Marmora, were sent under that general to the Crimea, where they won for themselves honour, and for their country allies amongst the great powers. Cavour made terms with Louis Napoleon, and in 1859 war was declared once more against Austria. The French and Italians won the battles of Magenta and Solferino in June, and then the French emperor, acting independently, agreed to a treaty which left the Austrians in possession of Venetia, from the Mincio eastward. The indignation of the Piedmontese, whose sovereign had, under Cavour's agreement with Louis Napoleon, to give up Savoy and Nice in return for this assistance, was intense; but the states of Central Italy voted their union to the kingdom of Victor Emmanuel, and were annexed in March 1860; and a few days after Southern Italy revolted from Francis II., the son of Ferdinand, the detested Bomba. Garibaldi and his volunteers, their expedition secretly favoured by Cavour, went to the support of the insurrection in May, and in September entered Naples. Cavour, with the consent of Louis Napoleon (who, however, maintained the pope in Rome, because his own position in France was strengthened by his championing the head of the Catholic Church), now sent an army into the papal states, which defeated the pope's troops at Castellidardo, joined Garibaldi, and helped him to defeat the Neapolitan generals on the Volturno. In October Victor Emmanuel entered the Abruzzi, and Garibaldi resigned his dictatorship and retired to his island farm. In February 1861 the first Italian parliament met at Turin, and Victor Emmanuel was proclaimed King of Italy. But Rome and Venice were not yet freed, and Cavour died in June of this year. In 1862 Garibaldi raised a body of volunteers to liberate Rome, and, having crossed to the mainland, was defeated at Aspromonte; the blame, however, fell chiefly on Rattazzi, who was then minister, and who had sought to follow Cavour's policy, and to reap the advantage of Garibaldi's expedition, but had neglected to first come to an understanding with France. The expressed sympathy of Europe brought about the September Convention of 1864, by which Louis Napoleon agreed gradually to withdraw the French troops on Italy's stipulation not to allow an attack on the pope's territory. By the last article of the convention, the capital was removed a step nearer Rome—from Turin to Florence. In 1866 the Austro-Prussian war, in which Italy took but an inglorious part as the ally of Prussia, added to the kingdom the coveted territory of Venice. In the same year the French garrison was withdrawn from Rome, and Mazzini demanded that the city should be captured. In 1867 Garibaldi and his volunteers gained a victory near Rome, and the French returned; the volunteers surrendered in November, and the general was arrested. But after the fall of the empire, in 1870, the new foreign minister of France, Jules Favre, declared the September Convention at an end, and the king, who had only prevented the democrats from moving by arresting Mazzini, was at length free to act. On 20th September he entered Rome, and the emancipation of Italy was completed. The pope retained the Vatican, the church of Sta Maria Maggiore, the Lateran palace, the villa of Castel Gandolfo,

with their precincts, and was voted an income of £150,000 out of the revenues of the state; yet the spiritual sovereign has borne but impatiently the loss of his temporal power, and frequent complaints and denunciations have been directed from the Vatican against the palace on the Quirinal. Meanwhile Italy, at last free and united, has become one of the great continental powers, as has been shown in the preceding sections of this article. It will be the hope of all who have followed the story of her long degradation and gallant recovery of freedom that this rapid growth may not, like her earlier precocious development in arts and commerce, be bought at the after cost of premature decay.

The later history of Italy has been uneventful. Brigandage, rife under the tyrannical rule of the Bourbons, and afterwards encouraged by their emissaries, has been gradually suppressed, education and public works have steadily advanced, and in the south the people have become more reconciled—at least, less inveterately hostile—to the laws. In January 1878 Victor Emmanuel died, and was succeeded by his eldest son, Humbert I. (born 1844); and one month later Pius IX. died also, and Leo XIII. became pope. The most important internal measures since then have been the wide extension of the franchise and the adoption in 1882 of the system of *scrutin de liste*, and in 1883 the resumption of specie payment. The popular interest in political questions so far is not great; but the government has been from time to time embarrassed by the agitation conducted by the extreme party of Irredentists, whose professed aim is to add to the kingdom all those districts of Europe where the Italian speech prevails. These, which they have named *Italia Irredenta* ('Unredeemed Italy'), embrace the southern Tyrol ('the Trentino'), Görz, Trieste, Istria, and Dalmatia, and also the Swiss canton of Tessin (Ticino), Nice, and the islands of Corsica and Malta; but it is mainly against Austria that the hatred of the Irredentists is directed. In 1883 the ministry denounced the schemes of the association, as aiming indirectly at the downfall of the monarchy, and at the same time extolled the triple alliance (of Italy, Germany, and Austria), into which Italy, exasperated at the extension of French influence in Tunis, had entered. To this same jealousy of France's encroachments on the southern Mediterranean shore may be attributed the erection into an Italian colony, in 1882, of a coaling station founded the year before at Assab, on the Red Sea. In 1885 Massowah was occupied, and in 1889 the Italian colonial territory was amalgamated under the name of Eritrea (see p. 240). Abyssinia had come to be looked on as under an Italian protectorate, but difficulties accumulated until in March 1896 an Italian force was routed at Adowa by the Abyssinian king. In the same year a treaty was concluded with France about Tunis; and the heir-apparent married the daughter of the Prince of Montenegro. In the early morning of 29th July 1900 King Humbert was assassinated at Monza by Angelo Bressi of Prato in Tuscany, and was succeeded by his son, Victor Emmanuel III.

The principal materials for Italian history during the middle ages will be found in Muratori's *Rerum Italicarum Scriptores* (25 vols. 1723-51; useful 'Indices Chronologici' appeared in 1885), and in the *Archivio storico Italiano* (vols. i.-xvi. 1838-51). See also Guicciardini's *Istoria d'Italia*, continued to 1814 by Carlo Botta; Muratori's *Annali d'Italia*; Cesare Balbo's *Sommario*; Bryce's *Holy Roman Empire*; and Villari's *Storia politica d'Italia* (8 vols. 1883 *et seq.*). Among books dealing with separate periods may be mentioned Hodgkin's *Italy and her Invaders* (from the fall of the empire; volumes i. to vi. 1880-91); Sismondi's *Republiques Italiennes du Moyen-âge*; Troya's *Storia d'Italia del*

Medio Evo (17 vols. 1839-59); Reuchlin's *Geschichte Italiens von der Gründung der römischen Dynastie* (4 vols. 1859-73); Maurice, *The Revolutionary Movement of 1848-49* (1887); and Nisco's *Storia civile*. Symonds's *Renaissance in Italy* is valuable, and Von Ranke's *History of the Popes* is necessary to a proper understanding of the national development. Finally, there is a useful little volume on Italy, by W. Hunt, M.A., in Professor Freeman's 'Historical Course.' Reference should also be made to the articles on the separate provinces and the great cities (Rome, Florence, Naples, Venice, &c.), and to the works cited there; and also to the numerous articles in this Encyclopædia on the principal characters in Italian history—from Odoacer to Cavour, Garibaldi, Mazzini, &c. See also ART, DRAMA, PAINTING, RENAISSANCE.

LANGUAGE AND LITERATURE.—Italian is one of the group of Neo-Latin or Romance languages—viz. languages the direct offspring of the Latin tongue as spoken by the Romans and imposed by them on the nations more immediately under their dominion. The chief subdivisions of the Neo-Latin group are French, Spanish and Portuguese, Provençal, Rumanian, and Italian. This last retains the closest resemblance to its prototype. The affinity between the Romans and the races of the Cisalpine Peninsula being closer than in the case of the other Latinised peoples, the phonetic changes introduced by them are less profound. The question as to whether the Neo-Latin idioms were much modified by the frequent Teutonic invasions of south-western Europe has given rise to prolonged discussion among philologists; but more recent methods of research seem to establish the fact that the influence of these invaders was slight, the more perfect language of the vanquished having imposed itself on the intellectually inferior conquerors. Neither is modern Italian derived entirely from the so-called 'rustic Latin,' or incorrect speech of the lower orders. The origin of the words which compose the modern tongue may be traced in as many cases to the speech of Cicero and Virgil as to that of the common folk. The differences between the ancient and modern languages are the outcome of the natural evolution of all living organisms which must undergo such changes as are necessary to life and growth. But so overwhelming was the prestige of Latin literature that this natural evolution was looked on with contempt by the learned everywhere. The struggle between the written but dead language and the various forms of the living speech was nowhere so protracted as in Italy, where the influence of Roman traditions and culture was supreme.

During this long period of evolution many dialects sprang up which still preserve their individual peculiarities. The conformation of the peninsula, its varying climates and soils, and the different origins of the races which inhabit it account for the variety and differences of these dialects. Their seemingly wide divergences are in reality mostly caused by pronunciation and not by structural changes. According to the classification of Guix (in his admirable study *Sui Dialecti d'Italia*), their principal divisions are: (1) In the north and north-west the *Gallio-Italian*—viz. Piedmontese, Lombard, and Emilian or Bolognese, in close affinity to the French in their mode of pronunciation and truncated terminations; (2) the *Venetian*, spoken also in the Italian Tyrol and parts of Dalmatia and Istria. This dialect is soft, harmonious, and more purely Italian. The subdivision of it is the Friulian, which preserves a close resemblance to the ancient Rhetian. (3) In the centre the pure *Italian* dialects—viz. Tuscan, Roman, with the nearly-related dialects of Umbria and the Marches, Campanian, in which Abruzzese and Apulian are included. (4) In the south and south-west the *Ibero-Italian*—viz. Sicilian, spoken also in the extreme south

of Calabria and part of Sardinia; Corsican, Sardinian, and Ligurian, or the dialects of the Genoese sea-coast. This last group presents marked traces of the close commercial intercourse with Spain and her long dominion in these parts of Italy.

As early as the 11th century the earlier-matured idioms of France and Provence had already taken shape in an abundant literature of their own which invaded the Italian peninsula, and the much-admired poetry of the troubadours threatened to stifle entirely the humbler growth of the soil. However, in the early part of the 13th century, in the famous centre of social life and culture formed by the brilliant court at Palermo of the Emperor Frederick II. of Hohenstaufen, a school of Aulic (or court) poets sprang up headed by the emperor himself and his friend and secretary, Pietro delle Vigne (died 1249). The Sicilian dialect formed the basis of the idiom used, but the large mixture of Latin words, and the too evident imitation of Provençal models, mark this school of poetry as an artificial product. After the death of Manfred, Frederick's unfortunate son (1266), the Sicilian school soon ceased to exist.

In various parts of the mainland more or less successful attempts were now being made to write in the vulgar dialects. Noteworthy is that of St Francis of Assisi and his followers to use the Umbrian dialects in religious lyrics during the 13th century, the most distinguished among this group being Jacopone da Todi (died c. 1306). The sacred dialogues, a primitive form of the mystery play, produced by this same school, may be regarded as the earliest germ of the national drama. An important group of lyric poets flourished in Bologna, then a centre of European learning and civilisation; their chief was Guido Guinicelli (died 1276), praised by Dante (*Purgatorio*, xxvii.) as the father of himself and all other singers of love. The contemporary Tuscan poets wrote philosophical lyrics full of overstrained sentiment, but in wonderfully pure Italian. Chief among them were Guido Cavalcanti (died 1300), the beloved friend of Dante, and the immediate precursor of the latter's lyric style; and Cino da Pistoia, a distinguished jurist-consult and admired sonnet-writer, whose death (1336) was bewailed in verse by the young Petrarch. Fra Guittone d'Arezzo (1215-91) and Francesco da Barberino (1264-1348) wrote didactic allegorical poems and songs; the epistles of the former are noteworthy as the earliest prose writings in the vulgar tongue. Among the leading political and learned men of Florence was Brunetto Latini (1210-94); his best-known work is *Il Tesorotto*, a kind of allegorical encyclopædia in verse, showing immense erudition. Dante speaks of him as his instructor and master (*Inferno*, xv.). To this time belongs the earliest important collection of prose tales, the *Cento Novelle Antiche*, collected by an anonymous but probably Florentine writer. It is in Tuscany, in the central zone of the peninsula, that the idiom at last takes definite shape in which the varied dialects of north and south are to find their representative type. The man who is to harmonise in a great masterpiece these varied elements of style and language, and to reveal to Italy and the world all the power and compass of the living speech, growth of his native soil, is the Florentine Dante Alighieri (May 1265-1321). Dante's supreme poetic genius and the strength and individuality of his noble character made his influence as great among his contemporaries as it has continued to be through all succeeding ages. Almost contemporary with Dante, and forming with him the triumvirate which makes the 14th century, or 'Trecento,' the golden age of Italian literature, stand Petrarch (1304-74) and Boccaccio (1313-75). Thus Italian

literature presents the strange phenomenon that it attains its zenith in its opening period. Petrarch, the precursor of the revival of classic studies which was to give the distinguishing mark to the following century, lives in fame, not by his voluminous Latin works, but by reason of the unequalled beauty of his songs and sonnets written in the despised idiom of the people. If we may say of him that he brought to perfection the language of lyric poetry, so may Boccaccio have the honour of giving form to prose by the language in which he clothed his tales. Around this imposing trio are grouped many lesser stars whose works, though inferior as to substance, are all distinguished by the same simple beauty of style. Francesco Stabile, known as Cecco d'Ascoli, is the author of a strange, semi-scientific poem, *L'Acerba*, in which he severely censures Dante's *Divine Comedy*. He was professor of Astrology at Bologna, and was burned for heresy in 1327. The Florentine Fazio degli Uberti produced, in imitation of the *Divine Comedy*, a long poem, *Il Dittamondo*, a wearisome versified account of imaginary travels; more successful were his graceful lyrics. The imitators of Petrarca during this century are of little importance, the most noted being Giusto da Valmontone (died 1449), author of a collection of lyrics, *La Bella Mano*. Among Boccaccio's followers are Ser Giovanni Fiorentino, author of a collection of tales called *Il Pecorone*, written about 1378, and the more original Franco Sacchetti (1330-99), who gives in his book of anecdotes a familiar and spirited picture of contemporary customs.

The earliest undoubtedly authentic historical work in Italian is the *Chronicle* written by Giovanni Villani, a leader in the commercial and political life of Florence, whose history he relates with vigour and simplicity. He died of the plague (1348), but his chronicle is continued till 1364 by his brother and nephew. The important *Cronaca dei suoi tempi*, by Dino Compagni, describes minutely the party strife in Florence (1300-1). Especially noteworthy for their graceful and pure diction are the letters of the famous St. Catharine of Siena (1347-80), and the *Fioretti* of St. Francis, a selection by an anonymous author of the sayings and doings of that holy man and his followers.

Though classic antiquity was naturally the source of all culture during the 14th century, still the great men of that age drew their more immediate inspiration from the religious and political movements of their day. The distinguishing mark of the 15th century, on the other hand, is the withdrawal of the cultured class from interest in popular events, and their contempt of the national language for literary uses. Latin becomes the only acknowledged literary medium. For a more detailed account of all the celebrated Humanists and their various patrons, see Symonds's *Renaissance in Italy*, and Roscoe's *Lorenzo the Magnificent* and *Leo the Tenth*.

This great revival or 'Renaissance' of Greek and Roman culture, which from Italy outwards affected the whole of Europe, was fostered by the splendid protection of the numerous princes whose rule was now gradually taking the place of the turbulent but life-inspiring freedom of the small republics. These patrons and their erudite courtiers have conferred a lasting benefit on posterity by the priceless libraries in whose collecting they vied with each other. Foremost amongst artistic and literary centres was Florence, under her Medici rulers, Cosimo, called Pater Patriæ, and his grandson, Lorenzo the Magnificent, who were the first also to encourage a return to the use of the vulgar tongue among the distinguished writers of their court. Leon Battista Alberti (1406-72) was one of the most zealous advocates for the restoration of

Italian. A wonderfully versatile genius, he excelled as architect, poet, and prose-writer both on art subjects and moral philosophy; his most important Italian work is a treatise 'On the Family,' of which the well-known dialogue on the same subject ascribed to Agnolo Pandolfini is supposed to have formed part. Angelo Politian (1454-94), one of the most brilliant ornaments of this court, wrote an exquisite eclogue, *L'Orfeo*, the first secular drama in Italian, although the *Canto Carnascialesco*, or rhyming dialogues sung by masqueraders at carnival time, may be considered an earlier form. Side by side with these are the friends Pico della Mirandola (1463-94), who has, however, left little but the fame of his vast erudition, and Girolamo Benivieni, author of much didactic and devotional poetry, which reflects the teachings of the great reformer and orator Savonarola, the opponent of Pagan culture, whose influence was supreme in Florence from 1489 till his execution in 1498. The two Florentines, Giovanni Rucellai (1475-1526) and Luigi Alamanni (1495-1556), wrote graceful poems in imitation of the Georgics. The revival of classic rhythms, attempted by Claudio Tolomei, has been more successfully carried out in modern times by Carducci (q.v.). In Naples a brilliant school of Latin poets flourished. Pontano (1426-1503) enjoyed much contemporary fame and influence; his more celebrated follower, Jacopo Sannazzaro (1458-1530), is remembered by his pastoral romance, with lyric interludes, *Arcadia*, written in Italian.

But the popular and typical product of this age is the narrative poem, or romantic epic. Rude translations of chivalrous poems from the French and Provençal had long been in use among the populace; the first, however, to ennoble the narrative poem was the Florentine Luigi Pulci (1432-84). His style is comparatively simple and free from Latinisms, and one of the distinctive marks of the romantic school in his work, as in all other literatures, is the breaking down of the classic barrier between the serious and the humorous. Contemporary with him was his more famous competitor, Matteo Boiardo (1434-94), an adherent of the dukes of Ferrara. To the same brilliant court belonged the famous Ariosto (1474-1533), who brought to perfection the romantic epic. In close connection with this new school are the burlesque-writers of the early 16th century. Most polished of these was Francesco Berni (1497-1535); he lived in the service of the Medici popes, and is said to have died of poison given by order of the notorious Duke Alexander de' Medici. Florence was the special home of these flippant and licentious poets, whose wit gave expression to the all-pervading scepticism and corruption of the age. Antonio Francesco Grazzini, called Il Lasca (1503-84), was the most brilliant of the 'Bernesque' imitators. He excels also as a writer of prose tales in the style of Boccaccio, while his contemporary, Matteo Bandello (c. 1480-1562), is the chief story-teller in Lombardy. A strange variety of serio-comic verse is that written in 'Lingua Macaronica,' or burlesqued Latin, by a monk of Mantua, Teofilo Folengo (1492-1544), under the pseudonym of Merlino Cocajns. Now mere literary curiosities, these humorous poems were immensely popular in their day.

In the 15th century the corruption and dissensions of her many rulers had reduced Italy to a state of dissolution, which left her an easy prey to foreign invaders, and the 16th century saw the completion of her political ruin. Her literature is trammelled by classic imitation and court servility. A corroding cynicism and want of moral sense are the characteristic note of the greatest writers, foremost among whom is Machiavelli (1469-1527); but his great genius and far-seeing patriotism redeem

his defects and ennoble his work. Next to him as historian comes his fellow-citizen, Francesco Guicciardini (1483-1540), who is a model of order and elegance. Every court in Italy had its chroniclers, but many of them wrote in Latin. Among these the most quoted is Paolo Giovio (1483-1552), attached to the papal court for many years.

The secret despatches of the Venetian ambassadors to their senate, from 1500 onwards, form a copious store of vivid and accurate historic information. Paolo Paruta (1540-98) has written a remarkable history of Venice. The growth of the secular drama was rapid at this time. Moulded entirely on classic models as to form, comedies now begin to represent living types and customs, while the tragic style remains stilted and artificial. The great names of Machiavelli and Ariosto are foremost amongst these comedy-writers. Full of wit and originality, mixed with obscenity, are the comedies of the infamous Pietro Aretino (1492-1557), whose celebrated Letters were used by him as a means of blackmailing the princes whom he attacked. One of the most applauded and licentious comedies was written by the Cardinal Dovizi di Bibbiena (1470-1520), *La Calandria*, and represented before Pope Leo X. In the didactic works *Il Cortigiano* of the Mantuan Castiglione (1478-1529), and the *Galateo* of the Tuscan G. della Casa (1503-56), we have models of elegant prose, which preserve for us pictures of the court-life of the times. The learned Cardinal Bembo (1470-1547), who during his lifetime gave the law in all matters of literary taste, did much by example and precept to help in the restoration of the vulgar tongue.

Two biographers are especially famous. Giorgio Vasari (1512-74), himself an indifferent artist, has left us a precious mine of information in his much-quoted *Lives of the Artists*; and unique of its kind is the graphic and picturesque autobiography of the great artist, Benvenuto Cellini (1500-71).

The end of the 16th and beginning of the 17th centuries saw political and religious liberty in Italy crushed under the dominion of the foreign invaders, and the increasing power of the popes. It is an age of decadence in art and literature, language is pompous and verbose, and the themes treated unreal. One name of enduring fame illumines this period, that of the unhappy Tasso (1544-95), a pure and earnest genius, and with him ends the pre-eminence of Italian literature in Europe. The pastoral drama, perfected by Tasso in his *Aminta*, and by his rival Guarini (1537-1612) in his *Pastor Fido*, became widely popular. In 1594 the *Dafne* of Rinuccini was produced with music, the earliest specimen of the musical drama.

The prolixity of description and abuse of metaphor, already in vogue towards the end of the 15th century, grew to such heights in the 17th century that 'Seicentismo' has remained a synonym for all that is false and exaggerated in style. The Neapolitan Giambattista Marino (1569-1625) is the leader of this school. His great poem, *Adonis*, amid all its grave defects, shows a powerful imagination and masterly ease in versification. Among a crowd of mediocre and servile lyricists, the Florentine Vincenzo Filicaja (1642-1707) is noteworthy for dignity and patriotic feeling. Gabriello Chiabrera of Savona (1552-1637) and his followers, Fulvio Testi of Ferrara (1598-1646), and Francesco Redi of Arezzo (1626-98), imitated with success the Greek lyricists. The imitations of Tasso's great epic were less successful than the parodies. A mock-heroic masterpiece is *La Scerchia Rapita* ('The Stolen Pál'), by Alessandro Tassoni of Modena (1565-1638). Of a less playful humour are the satires of the well-known Neapolitan artist, Salvator Rosa

(1615-73), conspirator with the famous Masaniello against the Spanish oppressors. The greatest names of this age belong to science. The writings of the foremost of all, Galileo, are models of clear exposition and choice diction. The works of the advanced thinkers of the time, nearly all natives of Southern Italy, and the best known amongst whom is Giordano Bruno (c. 1550-1600), belong to the history of philosophy. Venice still cherishes the name of Fra Paolo Sarpi (1550-1623), the scientist, historian, and opponent of Jesuit doctrines.

The dawn of the 18th century shows a dull level of mediocrity, and a false and affected literary taste, which the authority of the Roman 'Academy of Arcadia' did much to foster. Opponents of the prevailing fashion were the Venetians, Gasparo and Carlo Gozzi, the latter (1722-1806) being especially remembered by his graceful dramatised *Fable*. The more important Lombard poet, Giuseppe Parini (1729-99), writes with simple elegance in his satires. Most admired of his own contemporaries was the dramatic poet, Pietro Trapassi, known as Metastasio (1698-1782), poet-laureate and favourite at the imperial court of Vienna; but much greater is now the renown of his contemporary Goldoni (1707-93), who, by a return to the study of popular life and existing surroundings, became the reformer of the stage. To the end of this century belongs also Alfieri (1749-1803), the only great tragic writer whom Italian literature possesses. Roused to a hope of liberty by the great Revolution, Italy was again plunged into despair after the fall of Napoleon by the loss of the semblance of unity which had been given her, and, animated by hatred of the petty tyrants who returned to rule her, she began the long struggle for freedom. All the eminent literary men of this period helped the patriotic cause with their pen, and many suffered exile and imprisonment.

The talented Vincenzo Monti (1754-1828) was the leader of a new return to classic models in his eloquent and flowing poems. Pindemonte (1753-1828) is a noted follower of this school, and the more famous Ugo Foscolo (1778-1827). The most illustrious of the classicists is, however, Leopardi (1798-1837), the greatest Italian lyricist since the days of Petrarca. The tragedies of G. B. Niccolini (1782-1861), full of fiery patriotic allusions, were immensely popular. This classic school in turn gave place to the romantic. The centre of this movement was Milan, and its chief Manzoni (1785-1873), whose *Promessi Sposi* is the only really great historical novel in Italian. Two other noteworthy historical novelists are F. D. Guerrazzi (1804-74), who took a leading part in the Tuscan revolution of 1848; and Massimo d'Azeglio (1798-1865), one of the foremost political men of his time. More modern and original in style is the interesting novel, Nievo's *Confessione di un Ottomannico*.

Silvio Pellico, who has written many dramas, is better known by the touchingly natural account of his imprisonment by the Austrians. The romantic school produced no remarkable lyrics but those of Manzoni himself, and, although all over Italy fervent poets sang of freedom, only the satires of the Tuscan Giusti are of permanent value. The more noted of these minor poets are Berchet, Prati, Alardi, Paerio, and Gabriel Rossetti, connected with English literature through his illustrious children. Belli in Rome, and Porta in Milan, are noted poetic writers in dialect. The *Summary of the History of Italy*, by Cesare Balbo (1789-1853), the *History of the Florentine Republic*, by Gino Capponi (1792-1876), the *Universal History*, by Cesare Cantù (born 1807), are noticeable works. Rosmini (1797-1855), Gioberti (1801-1852), Mamiani (1800-85) are well known metaphysical and theo-

logical writers. Niccolò Tommaseo (1802-1874) is noticeable among critics and essayists for the vast extent of his learning. The eloquence and purity of style of Mazzini's political writings give them also literary value, and along with him among advanced thinkers must be mentioned Romagnosi (1761-1835).

Since the stormy times of her struggle for life, united Italy has produced few literary works of character and originality. The name of the poet Carducci is the only one of great distinction. Among the minor lyrists are Rapisardi, Guerrini (Stecchetti), and Panzucchi; and the lyrics in Tuscan dialect of Fucini are full of wit and nature. In Naples the talented young Gabriele d'Annunzio, both in poetry and prose, and Matilde Serao and Giuseppe Verga in their novels and stories, belong to the extreme school of realism. In the north the novelists Farina, Barrili, and the more eminent Fogazzaro show moderate tendencies. The vivid *Vita Militare* and other works of E. de Amicis, and the charming *Autobiography* of the sculptor Duprè, are well worthy of notice. Among dramatists, the works of Cossa, Ferrari, Giacosa, and Cavallotti are the most popular. Arrigo Boito, the composer, shows himself in his librettos and other works no mean poet.

The masterly historical works of P. Villari on Savonarola and Machiavelli are well known in translation to English readers. The versatile R. Bonghi has written interesting essays on various historical and political subjects.

Itasca Lake. See MISSISSIPPI.

Itch, or SCABIES, a skin disease produced by a minute mite (*Sarcoptes scabiei*), which burrows in the epidermis of most parts of the body, but especially about the hands. Its presence is marked by a small scaly elevation of the skin, by eruptions on the papillæ of the cutis are perforated, and by the irritating itching sensation.

The mite itself is white or yellowish, broad and flat, with two pairs of mouth parts, and four pairs of appendages. The males are scarcer and much smaller than the females, which are just visible to the naked eye. When they have entered the skin they do not leave it, but form tortuous burrows, through openings in which the embryos escape. The mites are passed by contagion from person to person, either by direct contact or by clothes or bedding. It is probably the embryos or larvæ which are usually thus transmitted. The above species also occurs on the horse, Neapolitan sheep, and lion; *S. squamiferus* occurs (causing mange) on dogs, pigs, goats, sheep, and apparently also for a short period on man; *S. minor* is also distinguished on cats and rabbits.

The itch was for a while regarded as a specific disease, the mite being unknown. Avenzoar, an

Itch-mite:

Abdominal view of female itch-mite, magnified 65 diameters.

Arabian physician of the 12th century, is said to have recognised its true nature. So does Scaliger (1537); and Adams figures the animal in a paper read in 1805 before the Royal Society. Amid some scepticism as to the mite during the early part of this century, M. Gales hoaxed the public by figuring as a substitute for the itch mite the familiar denizen of cheese. His trick was discovered by Raspail, and the existence of a real mite was more distrusted than ever, till in 1834 Remucci, a Corsican student, again demonstrated its presence and characters. It has been often studied since.

The usual cure for itch is found in baths, with abundant soap, or in rubbing with sulphur ointment. If these be not resorted to, the multiplication of the mite may give more serious trouble.

See ARACHNIDA, MITE, PARASITISM, SKIN; Delafond and Bourguignon in *Mém. Acad. des Sciences* (Paris, 1802); and treatises on Parasites by Leuckart, Küchenmeister, &c.

Ithaca, now THIAKI, one of the Ionian Islands (q.v.), the smallest of them except Paxo, is a long, narrow strip of land off the north-east of Cephalonia, and lies 20 miles west of the mainland of Greece. The surface is mountainous (2648 feet), and the coast steep and rocky. Area, 37 sq. m. Wine, currants, and olive-oil are largely grown. Goats are kept. Sponges and coral are fished for. The island is celebrated as the principality and home of Ulysses. Pop. 10,650. Chief town, Vathy. See Schliemann's *Ithaka* (1869).

Ithaca, capital of Tompkins county, New York, is picturesquely situated on Cayuga Lake, near the southern extremity, and on the slopes of the neighbouring hills, 35 miles NNE. of Elmira by rail. It has a large trade in coal, and a number of foundries, mills, and factories. Ithaca is the seat of Cornell University (q.v.). Pop. (1890) 11,709.

Itinerary (Lat. *itinerarium*, derived from *iter*, 'a journey'), the name given by the Romans to a written or pictorial account of the principal roads and routes in the empire, with the stations and distances between them. Of the former class the most important are the *Itineraria Antonini* and the *Itinerarium Hierosolymitanum*. The *It. Antonini* are two in number, one containing the routes through the Roman provinces in Europe, Asia, and Africa, and the other the principal sea-routes. They take their name from the Emperor Antoninus Caracalla, under whom they were published, as corrected up to his time, but they seem to have been originally prepared at an earlier date.—The *It. Hierosolymitanum* was drawn up in the 4th century A.D. for the use of pilgrims from Burdigala (Bordeaux) to Jerusalem. Another example of the same class is the *It. Alexandri*, showing the route of march of Alexander the Great through Asia. There is a collected edition of ancient *Itineraria* by D'Urbain (Paris, 1845). For the *Tabula Peutingeriana*, see PEUTINGER.

Iturbide, AGUSTIN DE (1783-1824), emperor of Mexico (q.v.) in 1822-23.

Itzehoe, the oldest town in Holstein, is situated in a valley backed by finely-wooded hills, 40 miles NW. of Hamburg by rail. Principal industries, sugar-refining, cotton-weaving, and the manufacture of machinery, chicory, and soap. Pop. (1890) 12,481. The original castle (Eselsleth), around which Itzehoe or Itzeheo gradually arose, was built by Charlemagne in 809. Itzehoe was twice destroyed by the Swedes during the Thirty Years' War.

Ivan (i.e. John), the name of two grand-dukes and four czars of Russia, three of whom are treated at RUSSIA. The best known, IVAN IV. (1530-84), commonly called Ivan the Terrible, reigned from 1533, and did much for the advancement of his

country in arts and commerce, as well as for its extension by arms. He was the first Russian sovereign to be crowned as czar. He subdued Kazan and Astrakhan, and from his reign dates the first annexation of Siberia. He concluded a commercial treaty with Queen Elizabeth, after the English had discovered (1553) the way to Archangel by sea. But his hand fell with merciless cruelty upon the boyars of his kingdom, and upon some of his towns, as Moscow, Tver, and Novgorod. In the last named some 60,000 people were slain in six weeks. This was, however, during the third period of his reign. The first marks the time during which he was under his mother's guardianship; and the second the era of commercial enterprise and territorial consolidation. Ivan died of sorrow for his son, whom three years before he had slain in a mad fit of rage. See Austin Pember, *Ivan the Terrible* (1895).

Ivanovo, or IVANOFF VOZNESENSK, the 'Manchester' of Russia, in the government of Vladimir, 210 miles by rail N.E. of Moscow. It has been the centre of the Russian cotton industry since the middle of the 18th century. Machinery is also made. Pop. (1897) 35,930.

Ivinghoe, a market-town of Buckinghamshire, 2 miles S.S.E. of Cheddington junction, and 38 N.W. of London. Pop. 1280. Ivinghoe Beacon (904 feet) belongs to the Chiltern Hills.

Iviza (anc. *Ebüssus*), the most south-westerly of the Balearic Isles (q.v.), lies 56 miles from the Spanish mainland. It is mountainous, and its coasts are indented by several bays. Area, 228 sq. m.; pop. 22,800. The principal products are salt and fruits, with a little lead. The chief town, Iviza, which is fortified, is the see of a bishop, and has a population of 7400.

Ivory is the name properly given to the tusks of elephants, a material which consists of that modification of *dentine* or tooth-substance showing in transverse sections lines of different shades running in circular arcs, and forming by their decussation minute lozenge-shaped spaces. By this character, which is presented by every portion of any transverse section of an elephant's tusk, true ivory may be distinguished from every other kind of tooth-substance, and from bone and all artificial imitations of ivory. Although no other teeth except those of the elephant present this characteristic, many other animals, such as the walrus, narwhal, hippopotamus, sperm-whale, &c., possess teeth or tusks which from their large size and from their density can be used for many purposes in the arts for which true ivory is employed. A small proportion of the ivory of European commerce comes from Ceylon, India, Burma, Cochin-China, and the islands of the Eastern Archipelago; but the greater part of the produce of the East is used in the regions of its production. The bulk of the ivory sold in the markets of London, Liverpool, and Antwerp is from the African elephant, and it comes from the interior by nearly every outlet from that continent. A small amount of ivory, brittle in quality, is also obtained from northern Siberia under the name of fossil ivory, being the tusks of the extinct mammoth embedded in the frozen soil of the region. The ivory of the tusks of the African elephant is held in the highest estimation by the manufacturer, on account of its superior density and whiteness. The tusks are of all sizes up to about 180 lb., but examples have been recorded exceeding 200 lb. in weight.

The value of ivory is in proportion to the size and soundness of the tusks. For the purposes of sale they are graded as teeth weighing 60 lb. and upwards, next from 40 to 60 lb., and third between 20 and 40 lb. Below the weight of 20 lb. they are

called *sericellous*, which are classed as hollows and solids. In consequence of its increasing scarcity by reason of the constantly-expanding demand for ivory, there has been a fluctuating but gradual rise in the price of the substance; but in recent years values have remained remarkably steady. Taking west coast African 'teeth' of good quality, the price may be said to have averaged £50 per cwt. during the ten years 1881-90, although according to quality it may range from £37 to £60 in a single sale; while from £50 to £60 may be taken as the price of good ivory in 1890. Selected teeth, and cuts made for special purposes, such as billiard ball solids, may command about £110 per cwt. The quantity annually imported into Europe averages 12,500 cwt., and in the East there is worked up about 2500 cwt. more, to procure which not fewer than 40,000 elephants must be sacrificed. Beyond this there must be many thousands of elephants killed every year in Africa to supply tusks for chiefs and head-men, which they use profusely for the ornamentation of their dwellings and graves. Ivory is conveyed to the coast by slave labour; and it has repeatedly been said that the extinction of the African elephant (which with the present enormous slaughter seems likely ere long to be achieved) would secure the suppression of the slave-trade. Among western communities ivory is chiefly in demand for knife and other handles, combs, piano keys, billiard balls, chess-men, and for carved figures and ornaments. Dieppe is the principal seat of the carved ivory trade; but nearly the half of the material used is worked up in England.

It has been assumed because of the large slabs of ivory used by ancient artists, some of which are still extant, that they possessed a method of softening, bending, and flattening the substance, the secret of which is now lost. One ancient author indeed mentions a means of softening and bending ivory by means of acid solutions, and various recipes are given by medieval writers for that purpose; but these are not found practicable. It is alleged that immersion in a solution of phosphoric acid renders ivory pliant and translucent; but that is done at the expense of its texture and elasticity—in short, such treatment deprives the substance of the very qualities which render it valuable.

The use of ivory can be traced almost to the earliest period at which there is evidence of the existence of man upon the earth. On fragments of mammoth tusks which have been picked up in the caves of Dordogne there have been found incised drawings of many animals, some now extinct and others no longer inhabiting Europe, executed with a spirit and fidelity which are simply marvellous. From that time downwards the records of every civilised community demonstrate the important place occupied by ivory, and the high commercial value it possessed. It was a substance distinctive of royal state and authority in ancient monarchies; and we read that King Solomon 'made a great throne of ivory.' There still exist examples of Egyptian inlaid ivory as ancient as the days of Moses, and Mr. Layard in his Nineveh excavations secured many Assyrian ivory carvings, believed to date nearly 1000 B.C., which are now preserved in the British Museum. When culture and art were at their height in ancient Greece ivory was lavishly used for carvings, sculpture, and objects of luxury; and many of the greatest and most famous works of Phidias and his fellow-artists were 'Chryselephantine' (q.v.) statues—gigantic works built of plates of ivory and gold, some of the figures reaching a stature of 40 feet. Among the Romans the use of ivory for purposes of luxury was equally extensive; and by them plates of ivory, joined as diptychs or

triptychs, were used as writing-tablets. Presents of such diptychs were commonly made by consuls on their appointment to officials within their jurisdiction, and among the treasures of classical times which yet exist are many remains of consular ivories. In the middle ages ivory came into use for ecclesiastical purposes in the form of tablets and diptychs for keeping registers and records, for crucifixes, statuettes of saints, caskets, reliquaries, croziers, book covers, &c. At the same period for secular use it was carved into chess-men, mirror cases, combs, 'oliphants' (hunting and tenure horns), and numerous other forms.

Ivory, VEGETABLE. This curious material is furnished by the palm-like plant, *Phytolaphis macrocarpa*, which grows on the Andean plains of Peru, and on the banks of the river Magdalena, and other parts of South America. It forms the type of a natural order, the Phytelphasiae, intermediate between the Palms and the Screw Pines (Pandaneae). The plant throws up a magnificent tuft of light-green pinnated leaves of extraordinary size and beauty, like immense ostrich-feathers, rising from 30 to 40 feet in height. The fruit, which is as large as a man's head, consists of many 4-celled leathery drupes aggregated together, and contains numerous nuts of a somewhat triangular form, each nut being nearly as large as a hen's egg; they are called *Corozo nuts* in commerce. The kernels of these nuts when ripe are exceedingly hard and white, in fact they resemble ivory so completely that few names have ever been better applied than that of vegetable ivory. They are in extensive use by turners in the manufacture of buttons, umbrella-handles, and small trinkets. Two or three millions of these nuts are now imported into Britain annually, and are chiefly used by the London and Birmingham turners.—For another ivory substitute, see CELLULOID.

Ivory-black. See CHARCOAL.

Ivory Coast, a part of the northern coast of the Gulf of Guinea, West Africa, embraces the districts between Cape Palmas and the river Assini. Its western portion belongs to Liberia; its eastern, now counted as part of the Gold Coast, is shared between Britain and France. The name bears no political meaning.

Ivrea, a town of Piedmont, on an eminence at the southern end of the Val d'Aosta, 38 miles NNE. of Turin by rail. Founded in accordance with an injunction contained in the Sibylline Books about 100 B.C., it has a cathedral which is supposed to occupy the site of a temple to Apollo. It was the seat of a Lombard duchy, and under the Carolingians of a marquise. One of the marquises of Ivrea, Berengar II., became titular king of Italy (q.v.) in the 10th century, and his grandson founded the line of the dukes of Burgundy. Incorporated with the empire in 1018, the town and marquise were given by Frederick II., in 1248, to the House of Savoy. Pop. 5883.

Ivry, a village of over 1000 inhabitants in the French department of Eure, 16 miles NNW. of Dreux. On the Plain of Ivry was fought, 14th March 1590, the famous battle between Henry of Navarre and the armies of the League. **IVRY-SUR SEINE,** a south-eastern suburb of Paris, on the Seine. Glass, earthenware, and chemical products are the chief manufactures. Pop. (1881) 18,442; (1891) 22,357.

Ivy (*Hedera*), a genus of plants of the natural order Araliaceae, consisting of shrubs and trees, mostly natives of tropical countries. The flowers have five or ten petals, and five or ten converging or consolidated styles. The fruit is a berry with

five or ten cells.—The Common Ivy (*H. helix*) is a well-known native of Britain, and of most parts of Europe, although it is more rare in the northern countries. Its long, creeping, branched stem, climbing on trees and walls to a great height, and closely adhering even to very hard substances by means of aerial rootlets, which it throws out in great abundance along its whole length, acquires in very aged plants almost the thickness of a small tree. Its 5-lobed, shining, stalked, evergreen leaves, clothing bare walls with green luxuriance, serve to throw off rain, and thus render damp walls dry, contrary to a common prejudice, that ivy tends to produce dampness in walls. In order to accomplish this, however, it requires to be pruned annually, for if allowed to run wild it admits rain to the walls by its projecting branches, and so renders even dry walls damp by preventing evaporation. It injures living trees by constriction when permitted to grow upon them. The flowering branches of ivy have ovate, entire leaves, very different from the others, and do not climb, but project from the climbing branches. Its small greenish flowers are produced in the beginning of winter, and the small black berries swell during winter and ripen in the following April. The berries are eagerly eaten by many birds, although they have a pungent taste, and contain a peculiar bitter principle called *hederine*,

Ivy, showing the aerial Rootlets.

and an acid called *hederic acid*; which are also found in a gummy exudation obtained by incisions from the stem, and occasionally used in medicine as a depuratory and a stimulant, and in varnish-making. An ointment made from the leaves is used for curing burns; the application of bruised leaves is serviceable for removing corns. In Egypt the ivy was sacred to Osiris, in Greece to Bacchus (Dionysos), whose thyrsus was represented as surmounted with ivy; the Romans mingled it in the laurel crowns of their poets.

There are numerous varieties of common ivy often planted for ornamental purposes, of which that generally known in Britain as *Irish Ivy*, and on the Continent as *English Ivy*, is particularly esteemed for its large leaves and luxuriant growth. They are distinguished from each other by the form of their leaves, and also by their colour, there being many shades of green and bronze, and not a few with gold and silver blotched leaves. Ivy grows readily from cuttings. *H. umbellifera*, a native of Amboyna, is said to produce a finely aromatic wood; and *H. terebinthacea*, a Ceylonese species, yields a resinous substance which smells like turpentine.

Ixion, a king of the Lapithae, the father of Phithons. Unable to find purification on earth for the treacherous murder of his father-in-law, he was taken up into heaven and purified by Zeus. But he attempted to seduce Hera, and for punishment he was chained to a fiery wheel, which rolled for ever in the sky.

Izard, the Pyrenean Hex. See GOAT.

J

is the latest addition to our alphabet, and has been inserted, as the tenth letter, after *i*, from which it was developed, just as *c* and *v* follow *u*, out of which they arose. In the 14th century it became the fashion, in Provençal and Catalan MSS., to lengthen the letter *i* into the form *j*, with a tail turned to the left, as a sort of ornamental initial at the beginning of words. The consonantal sound usually occurring at the beginning, and the vowel-sound in the middle or at the end of words, the initial form *j* after a while became conveniently but undesignedly specialised to denote the consonantal sound, the medial form *i* being retained for the vowel-sound. In the 15th century this usage, which never reached Italy, spread to France and England, but it was not before the middle of the 17th century that it became universal in English books, as is shown by the fact that in King James's Bible of 1611 the words *Jesus* and *judge* are printed *Iesus* and *iudge*.

The dot over the *j* is a curious survival. It is unnecessary as a diacritical mark, which it originally was (see I), as there is no danger, in its present form, of confusion with any other letters. The dot remains as a witness not only that *j* was developed out of *i*, but also of the fact that the evolution of *j* was later than the practice of dotting the *i*.

In English the symbol *j* is used to denote the sound of *dzh*, as in *journal*; in French of *zh*, as in *jour*; in Spanish it represents the hard *ch*, heard in the Scotch *loch*, as in *Jerez*; in German it retains the original *y* sound of the Latin consonantal *i*, as in *Jahor*. Thus, while German geographers write *Jeinissei* and *Jakut*, English maps have *Yenissei* and *Yakut*.

The consonantal sound of the English *j* is frequently expressed by *y*, as in *you* or *gin*, or by *g*, as in *knowledge*. The sound did not exist in Early English, but was introduced from France after the Norman Conquest. Hence in Middle English, before the symbol was invented, we find the sound represented by other devices. Thus, we have *Gires* for *Jews*, *goste* for *jest*, *cheur* for *jeur*, and *chaun* for *jeun*. Chaucer has *gylter* where the Bible has *judor*. The use of *j* is still extending, and we find *jibe*, *jail*, and *Jeffrey* occasionally used, instead of the more correct forms *gibe*, *gaid*, and *Geoffrey*.

We have unfortunately introduced our required French sound of *j* into Latin words which had the consonantal *i*, which the Romans pronounced as *y*; and we say *jan*, *jugum*, *janens*, *Jupiter*, *janens*, *janis*, *janus*, and *major*, where the Romans said *jan*, *yugum*, *yauens*, *Yupiter*, *yauens*, *yikou*, *hupus*, and *mayor*. In some inscriptions of the early imperial age the consonantal sound of *i* is denoted either by doubling the letter or writing it as a capital; 'huius,' or 'hulus,' representing the older spelling *huius*. In inscriptions of the later empire we find *Giree* for *Jove*, a usage adopted in modern Italian, in which we have *Gesù*, *Giovanni*, *Giuseppe*, and *maggiore*, from *Jesus*, *Johannes*, *Josephus*, and *major*, the use of the new letter

j being evaded in the same manner as in Middle English.

Jabalpur (*Jubbulpore*), chief town of Jabalpur district, Central Provinces, India, 228 miles by rail SW. of Allahabad. Standing at the junction of the East Indian and Great Indian Peninsula systems, Jabalpur is one of the most important railway stations in India. It is the second commercial town in the Central Provinces, has a trade worth about £2,000,000 annually, and manufactures cotton, tents, and carpets. Pop. (1877) 55,188; (1891) 84,481.—The *district* of Jabalpur has an area of 3948 sq. m., and a population of 748,146.—The *division*, one of the four into which the Central Provinces are broken up, has an area of 18,321 sq. m., and a pop. of 2,375,642, of whom three-fourths are Hindus.

Jabiru (*Mycteria*), a genus of birds of the Stork family (Ciconiidae); the chief distinction from the storks being that the bill is a little curved upwards. There are four species, which are found in Africa, India, Australia, and South America. The best known is the American Jabiru (*M. americana*), which is found from Mexico southwards to the Argentine Republic. It is a large bird, measuring from 4 to 5 feet in height, with white plumage, except on the head and neck, and a massive bill. The Jabirus of India and Australia are sometimes elevated to the rank of separate genera.

Jaborandi. Under this name a number of drugs, used for their sialagogue and diaphoretic actions, are known in Brazil. In Europe, however, only the leaflets of *Pilocarpus pennatifolius* are recognised as jaborandi. It is a shrub about 4 or 5 feet high, slightly branched, the branches erect, leaves alternate, long-stalked, imparipinnate, and 1 to 1½ feet long; leaflets opposite, in two up to five pairs, with a terminal leaflet. Each leaflet is about 4 inches long, oval-oblong, very obtuse or emarginate at apex, entire, coriaceous, and containing a number of glands which show as dots against the light. Flowers in racemes. This species is a native of Brazil. Jaborandi is official in the British Pharmacopœia, and is there defined as the dried leaflets of *Pilocarpus pennatifolius*. They contain an alkaloid, pilocarpine, C₁₁H₁₆N₂O₂, to which the effects of the plant are chiefly due; another alkaloid, jaborine; and two decomposition products of these, named respectively pilocarpidine and jaboridine. There are also present a volatile oil and a bitter substance. Jaborandi was first brought to the notice of medical men in Europe by Dr Coutinho of Brazil in 1871, and since then its action has been very fully investigated by numerous physiologists. When pilocarpine, or preparations taken from it, are taken internally there ensue very profuse salivation and perspiration, with depression of the circulation and disturbance of vision. Large doses cause in addition nausea, vomiting, and great muscular relaxation. The salivation and perspiration may be completely arrested or prevented by the administration of atropine. Locally applied to the eye it causes contraction of the pupil, and interferes with accommodation and vision. It is used in iritis, in Bright's disease,

and in various conditions where its sialagogue or diaphoretic effects are desirable.

Jacamars, a small family of brilliantly coloured birds (Galbulidae), inhabiting dense forests in tropical America east of the Andes. They are apparently dull and stupid, like their near relatives the Puff-birds (Bucconidae). The bill is long and usually straight, the feet are short and feeble, the front toes are united for some distance, the plumage exhibits a rich metallic splendour. They feed on insects. The white eggs (two) are laid in holes excavated in sandy banks. Technically this family, including about a score of species, is ranked among the Picariae, subdivision Picoideae, beside the puff-birds, and at a greater distance toucans and wood-peckers. The type is *Galbula gallinula*, resplendent in golden green; *Jacuncopsis grandis* is the largest species; the members of the genus *Urogallica* shine like black steel.

Jacana (*Paridae*), a family of birds allied to the Rails (Rallidae), but differing from them and from all other birds in possessing extremely long, slender, straight toes with long, sharp, pointed claws. They have pointed spurs on their wings, and many have a shield on the forehead like coots and moor-hens. They are found in all the tropics, and are birds of elegant plumage, frequenting swamps, lagoons, and marshes, where they walk on the broad floating leaves of aquatic plants with the greatest ease. The genus *Parra* (ten species) is

Common Jacana (*Parra jacana*).

widely distributed in the warm parts of South America, Africa, Asia, and also the Australian region. The Common Jacana (*Parra jacana*), a South American species abundant in Guiana and Brazil, is about 10 inches long, of a black colour, with neck and shoulders of a reddish-brown tint, and with green wing-feathers. The other genus (*Hydrophasianus*) of the family consists of only one species, the Pheasant-tailed Jacana, which is confined to the oriental region. It is the largest of all the Jacanas, and is found in India and Ceylon, where it inhabits marshes and reedy banks, feeding chiefly on vegetable matter, but also on shells and water insects. The flesh forms excellent eating.

Jacaranda Wood, a very hard, heavy, brown wood, also called *Rosewood*—though not the true Rosewood of commerce—from its faint, agreeable smell of roses. It is brought from South America, and is produced by several trees of the genus *Jacaranda*, of the natural order Bignoniaceae. Several species of this genus are called Caroba in Brazil, and are there accounted anti-syphilitic.—Several species of the nearly-allied genus *Tecoma* also have an extremely hard wood, as *T. pentaphylla*, a native of the Caribbean Islands. The Brazilian Indians make their bows of the wood of *T. toxicaria* or *Pao d'arco*.

Jacare. See ALLIGATOR.

Jacinth, or HYACINTH (Ital. *giacinto*, Lat. *hyacinthus*), a transparent, bright coloured variety

of Zircon (q.v.), of various shades of red, passing into orange and poppy-red. A perfect stone has a peculiar golden lustre mixed with its rich orange, and would formerly have fetched a high price; but the jacinth is no longer in fashion. By the ancients it was highly prized, and many fine intagli were executed in it, notwithstanding its hardness, which exceeds that of chalcidony and its varieties. Antique intagli in jacinth, however, almost invariably exhibit a somewhat rubbed or worn surface, which is believed to be due to the somewhat porous texture of the gem. Jacinth occurs in many basalts, tuffs, and some granitoid plutonic rocks, as, for example, near Expailly in Auvergne, and at Unkel on the Rhine, in Bohemia, Saxony, the Tyrol, Norway, the Urals, Greenland, &c. It is likewise met with in the form of granules and rounded crystals in the beds of certain streams, and in alluvial deposits, as near Expailly, in the Isere, and in certain streams in Ceylon. The jacinth or hyacinth of jewellers is not a zircon at all, but some variety of garnet—generally Cinnamon-stone (q.v.); and sometimes ferruginous quartz, which, from its abundance in gypsum at Compostella, in Spain, is called *Hyacinth of Compostella*.—*Jargoon* is the name given by the Singalese to another variety of zircon. It is usually gray or colourless, but often shows more or less ill-defined tinges of green, blue, red, and yellow. The surfaces of the crystals have a lustre almost rivaling that of the diamond. It was at one time supposed to be an inferior variety of the diamond, and is still occasionally sold as such.

Jack has been from the beginning generally used in England as the equivalent of John, the most common of Christian names, but it is not a little curious that it is really the French *Jacques* (till the 17th century pronounced as a dissyllable), and so through the Latin *Jacobus* and Greek *Jakobos* from the Hebrew *Ya'acob*, Jacob. Others, however, explain it as a shortened form of *Jankin*, an old diminutive of *Johann*, *Jehan*, or *John*; from the northern forms of which again, *Johakin* or *Jankin*, we have *Jockey* and *Jack*. The contempt that follows on excessive familiarity attaches itself in most European languages to the name John and its equivalents; thus we find the Italian *Gloria*, whence *Zanni*, our *Zany*; the Spanish *Juan*, as *bobo Juan*, 'a foolish John'; the French *Jean*, with its signification in compound terms of fool, cuckold, and the like; and our own vulgarisms, 'every man *Jack*' for all men without distinction, a '*Jack*-of-all-trades,' and a '*Johanny*' for a man of no particular account. Again, such compounds as '*Jack*-fool,' '*jack*-ass,' a '*jack*-pudding,' '*jack*-an-apes' (with intrusion of *n* for *Jack*-o'-apes) point in the same direction. From the sense of familiarity it came to be used of various implements which served instead of a boy or personal attendant, as in '*boot*-*jack*' and the kitchen '*jack*' which turns the spit. Somewhat similar are such usages as drinking *jack*, the '*jack*' for the small bowl aimed at in a game of bowls, and for the *knaves* in a pack of cards, as well as for a small pike as opposed to the full grown fish. Again, in complete harmony with the sense are such compounds as '*Jack*-a-lantern' and '*Jack*-a-lent' (Shakespeare, *Merry Wives*, III. iii. 27). *Jack* the Giant-killer and *Jack* and the Bean-stalk again show the same sense of familiarity without the accompanying contempt.

Jack, or JACA (*Artocarpus integrifolia*), a tree of the same genus with the Bread-fruit (q.v.), a native of the East Indies. It is a larger tree than the bread-fruit, and has larger fruit.

Jackal (Persian *shaykal*, Fr. *chaval*), the name of a number of species of the genus *Canis*

(see Dog), which are in many respects intermediate between the wolves and foxes. *Canis aureus*, being the most typical and widespread form, sometimes goes under the name of the Common Jackal. It

Common Jackal (*Canis aureus*).

measures about 3 feet in length, one-third of which is occupied by the tail, whilst the height is about 18 inches. The animal's build is strong, the muzzle is more acute than that of the wolf, blunter than that of the fox, and the bushy tail hangs down as far as the heel. The ears are short, less than one-fourth the length of the head, and far apart; the pupil of the eye is round. The colour is difficult to define: its ground-tint is a dirty fawn or grayish-yellow, becoming blacker on the back and sides; the under surface is white, reddish-yellow, or gray, and there are not unfrequently ill-defined dark bands on the shoulders and hind-quarters. The home of this species is the southern part of Asia, from India (including Ceylon) over Persia, Arabia, Palestine, and Asia Minor. Hence it has spread, perhaps following the track of armies, to North Africa, the Morea, and Dalmatia. In its habits as well as in its structure it exhibits characters intermediate between the wolves and foxes; like the former it hunts in packs, like the latter it is nocturnal. When on the chase these animals howl most dismally, and make the night hideous in regions where they abound. The singularly appropriate Arabic name *Deeb* ('howler') has reference to this habit. So far from avoiding the proximity of man, they penetrate into villages in search of offal and carrion, and they will also enter yards, houses, or tents in the most shameless manner, and carry off whatever takes their fancy, sometimes articles absolutely uneatable. They render a certain amount of service as scavengers and by killing vermin, such as mice, but this is by no means an equivalent for the damage they cause by their depredations in sheepfolds and poultry-yards, as well as orchards and vineyards. In many districts they constitute a veritable scourge, and can only be held in check by their congeners the dogs. They follow the larger carnivores to feed upon their leavings, a habit which has given them the reputation of being 'the lion's providers.' They are extremely cunning, and in oriental fable and proverb take the place of our reynard in this respect. The word 'fox' in the Old Testament probably refers in many cases to them. According to Sir Emerson Tennent, they habitually hide their booty, and if observed will seize some indifferent article and make off with it, as though that were the object of their solicitude, returning to their real spoil at the first convenient opportunity. The skull of certain jackals has a horny outgrowth some half-inch in length, eagerly sought for as a charm. Jackals are readily tamed, and the likelihood that they have given rise to some of the domestic dogs has already been alluded to (see Dog). The

Striped Jackal (*Canis lateralis*, *C. adustus*) is a connecting link between the wolf and jackal. The extreme length is a little over a yard, and the height rather less than half this; the pupil of the eye is somewhat elliptical and oblique, the ears widely separated. The species is rather rare, but has a wide distribution in Africa south of the Sahara. The Jackal-wolf (*Canis anthus*) is even more wolf-like than the last, and has been classed by different authors among the wolves or jackals. It is much smaller than the wolf, and inhabits Northern Africa. The Black-backed Jackal (*Canis mesomelas*) is somewhat more fox-like than the others, especially in the form of the head. The general build is low. The ears are large and close together, recalling those of the Fenec (see Fox). The area of distribution of this species extends from Middle Nubia down the east side of the continent to the Cape, and perhaps across to the west coast also.

Jack-a-lantern. See IGNIS FATUUS.

Jackass, LAUGHING. See LAUGHING JACKASS.

Jack-boots. See BOOTS AND SHOES.

Jackdaw (*Corvus monedula*), a species of crow, smaller than the rook and carrion crow, its utmost length being only about fourteen inches. It is black, with purplish wings and tail, and a dark-gray neck. It is a common resident in the British Islands, and is found nearly all over Europe, in many parts of which, however, it appears to be migratory; also in Asia and the north of Africa. It is not found in America. Its food consists of insects, snails, and worms. It builds its nest in holes of cliffs, ruins, and old trees. It frequents towns and villages, often making its nest in a chimney, by dropping down stick after stick till some of them become fixed in their oblique descent; and on these others are piled, affording a firm base for a nest of wool or other soft substance. The jackdaw lays from four to seven (usually five) bluish-white eggs, which are covered with small dark-brown spots. The jackdaw is a social bird. It is easily domesticated, and becomes very pert and familiar. It has considerable powers of mimicry, and may be taught to imitate very exactly the human voice.

Jackson, (1) a flourishing city of Michigan, capital of Jackson county, is on both sides of Grand River, which is here crossed by seventeen bridges (five of iron), 76 miles W. of Detroit, and 37 miles S. of Lansing, at the intersection of several railways. It has a number of flour, paper, and planing mills, and of foundries and machine-shops; the Michigan Central locomotive-works; breweries; and manufactures of furniture, carriages, wagons, boilers and machinery, farming implements, corsets, soap, &c., besides boots and shoes at the state-prison here. There is a flourishing general trade. Within the city limits, and close by, there are several mines of bituminous coal. Jackson was settled in 1830, and became a city in 1857. Pop. (1860) 4799; (1870) 11,447; (1890) 20,798. —(2) Capital of the state of Mississippi, on Pearl River, 45 miles E. of Vicksburg by rail, with regular streets, and houses standing for the most part among gardens. Here, besides the state-house, with a valuable library, are the usual state charitable institutions, and the penitentiary. There is a considerable trade in cotton. Pop. 5920. —(3) Capital of Madison county, Tennessee, on the South Fork of the Forked Deer River, 107 miles by rail S. by E. of Cairo, Illinois. It is the seat of the South western Baptist University (1874), is of some importance as a cotton market, and has planing and other mills and railway shops. Pop. (1890) 10,039.

Jackson, Andrew, General, seventh president of the United States, was born at Waxhaw on the southern border of North Carolina, March 15, 1767. His father, an immigrant from the north of Ireland, died a few days before Andrew's birth, and his mother and brother succumbed to the hardships of the revolutionary war. After being admitted to the bar at Salisbury, North Carolina, Andrew removed in 1788 to Nashville, then a frontier settlement, and was appointed public prosecutor. In 1791 he married Mrs Rachel Roberts, daughter of Colonel John Donelson, supposing that she had been divorced from her former husband. But the divorce not being legally granted until 1793, Jackson had the marriage ceremony repeated. These circumstances furnished material for malignant attacks, and the irritable Jackson fought several duels, in one of which, after he had a rib broken, he killed his antagonist. In the new state of Tennessee Jackson was a leading man; after helping to frame its constitution, he became its representative in congress in 1796, its United States senator in 1797, and a judge of its supreme court in 1798. This position he held until 1804, when he resigned. He gave some support to Aaron Burr's half-revealed schemes of conquest in the south-west, and when Burr was tried at Richmond in 1807 was still his steadfast partisan.

When war was declared against Great Britain in 1812, Jackson, being major-general of the state militia, offered his services and led 2500 men to Natchez, but General Armstrong, the new secretary of war, ordered him to disband them. Jackson, however, marched them in a body back to Nashville, where soon afterwards, in an affray with Colonel T. H. Benton, he was severely wounded. With his fractured arm still in a sling, the general took the field in September 1813 against the Creek Indians in Alabama. This campaign, in which his military genius was first effectively displayed, was closed by a decisive victory at the Horseshoe Bend of the Tallapoosa River, March 27, 1814. Henceforth he was familiarly called 'Old Hickory.' On May 31 he was made major-general in the regular army, and appointed to command the department of the South. Pensacola in Spanish Florida being then freely used by the British as a base of operations, Jackson took the responsibility of invading Spanish soil, stormed Pensacola, and when the British fleet withdrew marched to New Orleans, which was threatened by Sir E. Pakenham with 12,000 veterans. Jackson made his chief defence 4 miles below the city, where, along a ditch extending from a swamp to the Mississippi, he constructed earthworks. On January 8, 1815, under cover of a fog, Pakenham tried to carry these works by direct assault, but within half an hour the British were repulsed with a loss of 2600 men, including their commander, while the American loss was but 8 killed and 13 wounded. This battle was remarkable not only for the unprecedented disparity of loss, but for the fact that it was fought after the treaty of peace had been signed at Ghent, December 24, 1814.

In 1818 Jackson again invaded Florida, severely chastised the Seminoles, and executed Arbuthnot and Ambrister, convicted by court-martial, on very slight evidence, of inciting the Indians to war. After the purchase of Florida Jackson was its first governor, but soon resigned, and in 1823 he was again elected to the United States senate. In the next year as a candidate for the presidency he had the highest popular vote, but not a majority. The choice was, therefore, made by the House of Representatives from the three highest candidates, and J. Q. Adams was selected; but when he appointed Henry Clay secretary of

state, Jackson and his friends alleged that a bargain had been made, transferring Clay's votes to Adams. In 1828 Jackson was elected, having 178 electoral votes out of a total of 261. The first president from beyond the Alleghanies, he was a typical product of the new democratic era—fearless, honest, but prompt to decide everything for personal reasons. A striking feature of his policy was the sweeping removal of minor officials and filling their places with his partisans. This system was aptly described by Senator W. L. Marcy in 1831: 'To the victor belong the spoils.' Jackson's first cabinet was broken up in consequence of his characteristic but futile effort to compel social recognition of Secretary Eaton's wife by the families of the other secretaries. The second cabinet was in the main composed of abler men. Martin van Buren, who had been secretary of state, was nominated minister to England, but after he had gone abroad his confirmation was defeated in the senate by the casting vote of Vice-president Calhoun. This strenuous advocate of state sovereignty was now openly opposed to Jackson, as was shown at a banquet in 1830, when the president gave his famous toast—'The Federal Union—it must be preserved,' and the vice-president responded with another—'Liberty—dearer than the Union.' Congress readjusted the tariff in 1832, retaining the protective system which had prevailed since the peace of 1815, and against which South Carolina had protested as unconstitutional and oppressive. On November 24, 1832, its state convention adopted an ordinance of nullification. President Jackson's proclamation, prepared by Edward Livingston, who had succeeded Van Buren as secretary of state, ably argued the whole question, and declared a firm determination to execute the laws and preserve the Union. Under the leadership of Clay, congress adopted a compromise tariff in March 1833, and South Carolina repealed its ordinance.

The president's veto power was much more freely used by Jackson than by his predecessors. His most memorable veto was that of a bill to renew the charter of the United States Bank, which became the chief issue in the presidential campaign of 1832. Jackson, having obtained 219 electoral votes out of 286, resolved to destroy the bank by removing the government deposits. Two successive secretaries of the treasury refused to do so, but a third who was not confirmed by the senate issued the order. The senate censured this act as usurpation, but Jackson had a closing triumph when the censure was expunged on January 16, 1837. In his administration the national debt was fully paid in 1835, and the surplus revenue which accumulated was ordered to be distributed to the several states. In foreign affairs Jackson won credit by enforcing the claims for the spoiliations committed by French vessels during the wars of Napoleon. In 1831 France by treaty agreed to pay \$5,000,000, but afterwards delayed payment. The president then recommended to congress to seize French vessels to make up the amount, and France after a protest paid the claim. Jackson's second term having expired on March 4, 1837, he retired to private life at the Hermitage, near Nashville, whence he still watched with keen interest the great political movements of the time. He died at the Hermitage, June 8, 1845.

The most complete biography is by James Parton (3 vols. New York, 1860). For Jackson's administration, T. H. Benton's *Thirty Years' View*, and Von Holst's and other histories of the United States should be examined. See also the Life by W. G. Sumner, in the 'American Statesmen' (1882), and that by Dyer (1891).

Jackson, Thomas Jonathan, an American general, better known as 'Stonewall Jackson,' was

born at Clarksburg, West Virginia, 21st January 1824, graduated at West Point in 1846, entered the artillery, and gained two brevets in the war with Mexico. He retired from the army in 1851, and became professor in the Virginia Military Institute, where he was more noted for his conscientiousness and religious earnestness than for his success as a teacher. He took command of the Confederate troops at Harper's Ferry on the secession of Virginia, and commanded a brigade at Bull Run, where his firm stand gained him his *nom de guerre* of 'Stonewall.' Promoted to major-general, in the spring of 1862, in the campaign of the Shenandoah valley, he out-generalled McDowell, Banks, and Fremont, and eventually drove back upon the Lower Shenandoah these three Federal armies, two of them of superior strength to his own. Then, hastening by forced marches to Richmond, he turned the scale at Gaines's Mills (27th June), and, the Confederate capital relieved, returned to defeat Banks at Cedar Run in August. He then seized Pope's depot at Manassas, and his corps bore the brunt of the fighting in the victorious second battle there on 30th August. On 15th September he captured Harper's Ferry with 13,000 prisoners and 70 cannon, and the next day, after a trying night march, arrived at Sharpsburg, where his presence, in the battle of Antietam, saved Lee from utter disaster. Advanced to lieutenant-general, he commanded the right wing at Fredericksburg (13th December), and at Chancellorsville on 1st May 1863 drove Hooker back within the Wilderness. All next day Jackson was on the march, moving round the flank of the National army; at nightfall he fell upon its right and drove it back on Chancellorsville. Returning from a reconnaissance, his party was fired on by some of his own command, and Jackson received three wounds. His left arm was amputated; but pneumonia set in on the 7th, and on the 10th May he died. Jackson was the idol of his troops; and his power over his men was justified as much by his soundness of judgment as by his personal fearlessness. No single death was so severe a blow to either side. See Lives by Dabney (1866), Cooke (1866), his wife (1892), Parton (1893), and G. F. Henderson (1898).

Jackson, WILLIAM (1730-1803), musician, was born at Exeter, where, after some years in London, he in 1777 became organist of the cathedral. He published many songs and canzonets, besides sonatas, dramatic pieces, &c., some of his compositions having great vogue in their day.

Jacksonville, (1) capital of Duval county, Florida, and the principal business town in the state, is on the St. John's River, 23 miles from its mouth. The meeting place of five railways, it is 165 miles by rail E. of the state capital, Tallahassee. The streets are wide and well shaded; there are numerous hotels, chiefly for the accommodation of invalids and winter visitors. The city has a large coast trade, besides an active river trade. The chief exports are lumber, cotton, moss, oranges and marmalade, and early vegetables. Pop. (1880) 7659; (1890) 17,291—more than doubled.—(2) Capital of Morgan county, Illinois, stands in a fertile prairie region, at the junction of several railways, 34 miles W. by S. of Springfield. It is a pleasant town, and noted for its schools. Here are the Illinois College (Congregational; founded 1830), the Illinois Female College (Methodist; founded 1847), a conservatory of music, and other educational institutions; and here, too, are state asylums for the blind, the deaf and dumb, and the insane, and an asylum for the idiotic and feeble-minded. There are manufactures of woollens, paper, machinery, boilers, lumber, furniture, confectionery, &c. Pop. (1880) 10,927; (1890) 12,935.

Jacob (Heb. *Ya'aqob*), one of the three chief Hebrew patriarchs, second son of Isaac and Rebekah, whose history and character are graphically described in the Book of Genesis. He and his family followed Joseph to Egypt, where he lived for seventeen years; and, dying there, he was carried to Hebron for burial. Many see in the history of Jacob (on whom Israel, the name of the nation, was also conferred) an ethnological record rather than a personal one. Mention is frequently made of Jacob both in the Old and New Testaments, and there are also many legends about him in Rabbinical and Patristic, as well as in the Mohammedan literature. The names *James*, *Jacques*, *Giuseppe* are all, as well as *Jacob* and *Yakob*, various modern derivatives from the Hebrew patriarch's name. See JEWS.

Jacob, BILLOPHILE. See LACROIX, PAUL.

Jacobabad, a town of Upper Sind, 26 miles NW. of Shikarpur by rail, near the Beluchi frontier, has cantonments, a residency, and accommodation for the trade caravans from central Asia. Here is the memorial tomb of General John Jacob, commandant of the Sind Horse, who founded the place in 1847, and died here in 1858. Pop. 11,352, including cantonments.

Jacobi, FRIEDRICH HEINRICH, a German philosopher, born at Düsseldorf, 25th January 1743. The son of a merchant, he was trained at Frankfurt and Geneva for a mercantile career. But, abandoning business, he was in 1770 appointed councillor of finance for the joint duchies of Jülich and Berg, and thenceforward devoted himself principally to literary and philosophical pursuits. He maintained an active correspondence with Goethe, Hamann, Bonterwek, and was acquainted with Wieland, Herder, Lessing, Hemsterhuis, and others. In 1804 he was summoned to Munich in connection with the newly-founded Academy of Sciences, of which he became president in 1807. He died at Munich, 10th March 1819. Jacobi was not a systematic thinker; he elaborated no system of philosophy. He had become convinced of the truth of one or two leading ideas; and from the standpoint they gave him he examined the chief modern philosophies that were known in his day. His distinguishing doctrines are these: philosophy as elaborated by the understanding cannot transcend the sphere of sense-given materials, and consequently can never get conviction of the existence of such things as God, immortality, &c.; but man has yet another faculty whereby he has immediate conviction of the real existence of things—viz. reason; by this faculty we have immediate conviction or belief not only of the reality of objects perceived by the senses, but also of the reality of the highest verities that lie beyond the apprehension of sense. Taking these views for his guidance he successively examined Spinozism, in *Ueber die Lehre des Spinoza*, in *Briefen an Mendelssohn* (1785); Hume's teachings and Kant's, in *David Hume über den Glauben, oder Idealismus und Realismus* (1787); and Schelling's philosophy, in *Von den göttlichen Dingen und ihrer Offenbarung* (1811). He also expounded his teaching in philosophical romances—*Waldemar* (1779) and *Ulbricht's Briefsammlung* (1781)—in an *Open Letter to Fichte* (1799), and other occasional writings. His works appeared at Leipzig in 6 vols. in 1812-24. See monographs on him by Kuhn (1834) and Zirngiebl (1867).

Jacobi, KARL GUSTAV JAKOB, German mathematician, was born at Potsdam, 10th December 1804. He studied at the university of Berlin, and in 1827 was appointed extra ordinary, and two years later ordinary professor of Mathematics at Königsberg. Jacobi excelled in analytical mathematics;

his name is best known from his discovery of elliptic functions. Besides this he did most valuable work in connection with differential equations and the theory of numbers: his name is perpetuated in the theory of determinants. In 1829 he published his most celebrated work, *Fundamenta nova Theoriae Functionum Ellipticarum*, for which he received the medal of the Academy of Sciences of Paris. Most of his other investigations were published in *Crelle's Journal für Mathematik*. Jacobi was acquainted with Gauss, Legendre, Abel, and other great mathematicians of his own day. In 1842 he retired from his chair, owing to ill-health, and settled at Berlin. He died in that city on 18th February 1851. His *Gesammelte Werke* (7 vols.) were published by the Berlin Academy in 1881-91.

Jacobins, the members of a political club which exercised a very great influence during the French Revolution. It was originally called the *Club Breton*, and was formed at Versailles, when the States-general assembled there in 1789. It then consisted exclusively of members of the States-general, all more or less liberal or revolutionary, but of very different shades of opinion. On the removal of the court and National Assembly to Paris this club began to acquire importance. It now met in a hall of the former Jacobin convent in the Rue St Honoré, Paris: the Dominicans of France having come to be known as Jacobins from their chief Paris establishment being that of St Jacques (*Jacobus*) in the Rue St Jacques. Hence the revolutionary association received the name of the Jacobin Club, which was first given to it by its enemies; the name which it adopted being that of the *Society of Friends of the Constitution*. It now also admitted members who were not members of the National Assembly, and held regular and public sittings. It exercised a great influence over the agitation, of which the chief seat and focus was in the capital, and this influence was extended over the whole country by affiliated societies. Its power increased, until it became greater than that of the National Assembly. It formed branch societies or clubs throughout France, of which there were soon not less than 1200. When the National Assembly dissolved itself in September 1791, the election of the Legislative Assembly was mainly accomplished under the influence of the Jacobin Club. Almost all the great events which followed in rapid succession were determined by the voice of the club, whose deliberations were regarded with more interest than those of the Legislative Assembly. It reached the zenith of its power when the National Convention met in September 1792. The agitation for the death of the king, the storm which destroyed the Girondists, the excitement of the lowest classes against the *bourgeoisie* or middle classes, and the reign of terror over all France were the work of the Jacobins. But the overthrow of Robespierre on the 9th Thermidor 1794 gave also the deathblow to the Jacobin Club. The magic of its name was destroyed; and the Jacobins sought in vain to contend against a reaction which increased daily both in the Convention and among the people. A law of October 16 forbade the affiliation of clubs, and on November 9, 1794, the Jacobin Club was finally closed. Its place of meeting was soon after demolished.—The term Jacobins is often employed to designate persons of extreme revolutionary sentiments. For the *Anti-Jacobin*, see CANNING.

Jacobites (from the Lat. *Jacobus*, 'James'), the name given after the Revolution of 1688 to the adherents of the exiled Stuarts—James II. (1633-1701) and his son and two grandsons, James Francis Edward, the Chevalier de St George (1688-

1766), Charles Edward (1720-88), and Henry Benedict, Cardinal York (1725-1807). Those adherents were recruited from the Catholics, the Nonjurors, the High Churchmen and Tories generally, discontented and place-seeking Whigs, the Episcopalians and Highlanders of Scotland, and the great body of the Irish people. Oxford throughout was a great Jacobite centre, a zealous upholder of 'passive obedience' and the 'divine right of kings;' whilst Cambridge, on the other hand, was all for a Protestant succession. First came the battle of Killiecrankie (1689), where fell Graham of Claverhouse, and the Irish campaign (1690-91), with its battle of the Boyne and the treaty of Limerick; next, in 1696, the Assassination Plot, the chief actor in which, Sir George Barclay, escaped, but for which Sir John Fenwick, Sir William Parkyns, and Sir John Friend were executed. Then in 1715 there was the twofold rebellion—one in the Highlands under the Earl of Mar, another in the Border country under Thomas Forster, M.P., and the Earl of Derwentwater. Both practically ended, in spite of the Chevalier's subsequent landing, on the self-same day (13th November) with the indecisive battle of Sheriffmuir and the surrender at Preston, where nearly two-thirds of the 1500 prisoners were Scots. Seven nobles were sentenced to death, but only Kenmore and Derwentwater suffered, Nairn, Carnwath, and Widdrington being reprieved, and Nithsdale and Wintoun escaping from prison, as likewise did Forster. Not for the first or the last time, the inferior prisoners fared worse than the principals, twenty-six being executed, while over a thousand submitted to the king's mercy, and petitioned to be transported to the American plantations. Alberoni's expedition to the West Highlands (1719), with its 'battle' of Glenshiel, was a petty affair compared with the '15 or with the nine months' rebellion of the '45, whose hero throughout, as indeed of the whole Jacobite movement, was 'Bonny Prince Charlie.' It opened with his landing in the Hebrides (23d July), and closed with his crushing defeat at Culloden (16th April 1746), intermediate events being the victory of Prestonpans, the capture of Carlisle, the raising of the Manchester regiment, the turning at Derby (6th December), and the victory of Falkirk. This, more than the '15 even, was mainly a Scottish, mainly indeed a Highland, rebellion. The English Jacobites as a body held aloof; and of the chief victims beheaded, one only, Charles Radclyffe (Derwentwater's brother), was an Englishman. The others were the Earl of Kilmarnock, Lord Balmerino, Sir John Wedderburn, and Lord Lovat. The Earls of Cromartie and Traquair were let off, and nearly a thousand prisoners had their death-sentence commuted to transportation or forced enlistment; but fifty were hanged. In stout old Balmerino's avowal, 'If the Great Mogul had set up his standard I should have followed it, for I could not starve,' we see one type of the Jacobite; another, much baser, was Lovat, who played for a dukedom, whilst hoping to risk nothing, for he sent his son off to fight, and himself stayed at home. The last Jacobite hanged (on 7th June 1753) was Dr Archibald Cameron, brother to Lochiel; and in 1772 the last of the Jacobite heads fell down from its spike upon Temple Bar.

This sketch by no means exhausts the list of notable Jacobites, which comprised at one time or another Jeremy Collier, Sacheverel, Charles Leslie, Bolingbroke, Harley, Ormond, Marshal Keith, Rob Roy, William Law, Bishop Atterbury, Carte, Hearne, Dr King, Patten and Murray of Broughton (the two Julians of the '15 and the '45), Flora Macdonald, Sir Robert Strange, and Samuel Johnson. One remembers the Doctor's words about his pension (1762): 'Now that I have it,

I am the same man in every respect that I have ever been; I retain the same principles. It is true that I cannot now curse [smiling] the House of Hanover, nor would it be decent for me to drink King James's health in the wine that King George gives me money to pay for. But, sir, I think that the pleasure of cursing the House of Hanover and drinking King James's health are amply over-balanced by three hundred pounds a year.' There spoke an honest Jacobite, and there too spoke the spirit of the age. Jacobitism might linger on as a tradition among the Nonjurors, the very last of whose bishops died in 1805; but as an active principle it had long since become extinct, the reason of such extinction being less the disasters of its adherents or the worthlessness of the cause than the growing prosperity of the nation at large. *Bravi possidentes* had a double application, to subjects no less than to sovereigns.

The posthumous Jacobitism of the 19th century—'Charlie o'er the Water nonsense,' as Borrow terms it—was largely an outcome of Scott's splendid romance, *Waverley* (1814); and many, perhaps most of our best-known Jacobite lyrics were composed by post-Jacobite poets—Burns, Scott, Hogg, Lady Nairne, William Glen, Allan Cunningham, &c. This same 19th century, which has heard mass of requiem said for Prince Charles Edward by a Protestant minister (1888), and which has seen the Stuart Exhibition (1888-89), has not been without its two Stuart pretenders. They were 'John Sobieski Stollberg Stuart, Count d'Albanie' (1795-1872), and his brother 'Charles Edward, Count d'Albanie' (1799-1880), who were certainly the sons of Lieutenant Thomas Allen, R.N., and who claimed that he was the son of the young Chevalier.

S. Terry; the *Culloden Papers* (1815); Hogg's *Jacobite Relics* (1819); R. Chambers's *Jacobite Memoirs* (1834), and *History of the Rebellion of 1745* (1828; 7th ed. 1870); Jesse's *Memoirs of the Pretenders and their Adherents* (1845); Mrs Thomson's *Memoirs of the Jacobites* (1845-46); Dr Doran's *London in Jacobite Times* (1877); W. K. Dickson, *The Jacobite Attempt of 1719* (Scot. Hist. Soc., 1895); Bishop Forbes, *The Lion in Mourning* (Scot. Hist. Soc., 3 vols., 1895-96); and A. Lang's *Prince Charles Edward* (1900).

Jacobites, in Church History. See GREEK CHURCH, Vol. V. p. 398.

Jacob's Ladder (*Polemonium aculeum*), a herbaceous perennial plant of the natural order Polemoniaceae, common in the centre and south of Europe, and found also in the temperate parts of Asia and North America. It has a smooth stem $\frac{1}{2}$ to 2 feet high, and a terminal panicle of bright blue (sometimes white) flowers, with wheel-shaped 5-lobed corolla. Great medicinal virtues were once ascribed to it, but the only quality which it seems to possess is a slight astringency.

Jacobus, a gold coin, of the value of twenty-five shillings sterling, struck in the reign of James I. (1603-25).

Jacotot, JEAN JOSEPH, the inventor of the 'universal method' of education, was born at Dijon, in France, on 4th March 1770. In the course of his chequered career he was successively soldier, deputy-director of the Polytechnic School, military secretary, and the holder of various professorial chairs, as of Mathematics, Roman Law, &c. He retired to Belgium in 1815, and three years later was appointed lecturer on the French language in the university of Louvain, and afterwards director of the military Normal School. He died at Paris, 30th July 1840. The fundamental

principles upon which his system of education rests are that the mental capacities of all men are equal; the unequal results of education depend almost exclusively upon will; every person is able to educate himself, provided he is once started in the right way; knowledge should be acquired in the first place through instinctive experience, or by the memory. For example, in imparting a knowledge of a language, he began by making the pupil commit to memory a single passage; then he encouraged him to study for himself, first the separate words, then the letters, then the grammar, and lastly the full meaning and import. Jacotot's system has some points of resemblance to Hamilton's (see HAMILTON, JAMES). He expounded his views in *Enseignement Universel* (1823). See Life by A. Guillard (Paris, 1860).

Jacquard Loom, named after the inventor, Joseph Marie Jacquard (1752-1834). See WEAVING.

Jacquemart, JULES (1837-80), French etcher. See ENGRAVING, Vol. IV. p. 380.

Jacquerie, the name given to an insurrection of peasants in France in 1358, when the French king John was a prisoner in England. The nobles called the peasants contemptuously 'Jacques Bonhomme'; hence the word Jacquerie. The rising was caused by long-continued oppression on the part of the nobles. It broke out in the neighbourhood of Paris, but extended to the banks of the Marne and the Oise. The magnitude of the danger forced the nobles to make common cause, and on 9th June the peasants were defeated with great slaughter near Meaux. This put an end to the insurrection.

Jactitation of Marriage is a false pretence of being married to another—a wrong for which the party injured could formerly obtain redress by a suit in the Ecclesiastical Court. Jurisdiction in such suits now belongs to the Probate and Divorce Division of the High Court of Justice; but the suit is unknown in modern practice, the English law being clear enough to enable parties to ascertain without litigation whether they are married or not. In Scotland, where the law is not so clear, the suit of declarator of putting to silence (i.e. putting an end to pretended claims) answers the same purpose as a suit for jactitation. Thus, in the famous Yelverton case (1861) the lady's action for declarator of marriage was met by a cross-action for declarator of putting to silence.

Jade is a name applied to about 150 varieties of ornamental stones, but should be properly restricted to the mineral Nephrite (q.v.), so called from the Greek *nephros* because it was supposed by the ancients to have virtue in renal diseases. The name is from the Spanish *ipada*, 'the flank' (from the Latin *ilica*), because it was believed to cure pain in the side; and the mineral was brought by the Spaniards from Mexico. True jade is a native silicate of calcium and magnesium, tough, and of various shades of green, yellowish-gray, and greenish-white. It is never crystalline, and it is very hard, but not excessively so, and is remarkable for being less hard when freshly broken than after exposure. The specific gravity varies from 2.91 to 3.06. Jade has been reported in isolated cases in Prussia, Turkey, and Corsica, but important deposits are unknown in Europe. It is principally found in China, Siberia, New Zealand, and in some of the islands of the South Pacific, while its occurrence has also been reported in British Columbia and Alaska. Although jade ornaments were brought by the Spaniards from Central and South America, the mineral is not found there *in situ*. It is doubtful, moreover, if the majority of these reputed jade ornaments were

of true jade. The 'Amazon-stone,' for instance, is not, but is a variety of microcline felspar, while the 'Bowenite' of North America is really a variety of serpentine. Many objects exported from China as of jade are really of serpentine. A variety of jade found in New Caledonia and the Marquesas is known as 'Oceanic jade,' differing from the oriental variety in the proportions of lime and magnesia. The New Zealand jade also differs from the Asiatic, and many of the stones used by the Maoris known as *haua-kawa* do not contain some of the inseparable ingredients of true jade. The real jade found in New Zealand is known to the Maoris as the *puatani* or 'green-stone,' and is found along the west coast of the south island. They work it into amulets, ornaments, and even axe-heads on account of its hardness. In New Caledonia and some of the other Pacific islands jade is also used for axe-heads, and thus has become known to mineralogists as axe-stone.

Nowhere is jade found so extensively and prized so highly as in China. And yet a good deal of the so-called China jade is really jadeite—which is a silicate of alumina and sodium, and therefore a different chemical compound from true jade. Jadeite has a brighter colour, and is harder than jade, while its sp. gr. ranges from 3.28 to 3.35. Jadeite is also found in Burma, near Blamo, and is doubtless the substance of which many of the old Mexican and Central American ornaments were made. An Egyptian scarabæus in jadeite has been found, and axes of jadeite have been discovered in the lake-dwellings of central Europe, although the mineral itself is unknown in Europe.

In China jade is most ingeniously and elaborately carved. It is called *Yu-chi*, or 'yu-stone,' and has for ages been obtained from the Kuen-lun Mountains, where it is found in veins among the schistose and gneissose rocks of the Kura-kash, and the south of the Khotan province. Jade from that district has been known to the Chinese for over two thousand years. Very fine dark-green jade is found near Batongol, in Siberia, in boulders.

The mines of Chinese Turkestan are, so far as is known, the only mines which are regularly worked. There are over one hundred of them, riddling one large mountain-side with dark tunnels, giving access to long galleries winding in all directions; in some cases piercing right through to the other side of the mountain. The mineral is found in veins several feet in thickness, but so full of fissures that perfect blocks are not often found of more than a few inches thick. It is for this reason that large pieces are so valuable, and are usually reserved for the imperial tribute. At Canton there is a great jade market, where the mineral itself as well as all sorts of articles made from it are on sale. The ornaments are mostly bracelets, brooches, ear-rings, finger-rings, and hairpins, and these are as dear to the Chinese ladies as diamonds are to their Caucasian sisters. A necklace of green jade beads will cost £1000; two buttons suitable for a mandarin will fetch £30; while for a moderate-sized piece of the vivid green, which is much sought after, from £500 to £600 will be paid. The stone is exceedingly difficult to work, and hence the great cost of carved specimens; but even at Moulien a pair of rough bracelets, not of the finest quality, will fetch £20 or £30.

Jade ornaments have been found among the lake-dwellings of Switzerland—at the lakes of Biemme, Zurich, and Pfaffikon; stone celts have been found in dolmens in France which resemble jadeite, but with a larger proportion of iron, and are now known as *chloromachadite*; and implements of the Neolithic age in western Europe, once supposed to be of jade, are now recognised as of *fibrolite* (a silicate of aluminium, sp. gr. 3.2).

There is no natural jade among the rock formations of Switzerland, so that the ornaments of the lake-dwellers must either have been brought by their ancestors from Asia, or have been obtained in barter from some of the nomadic races of pre-historic times. Dr Schliemann reported jade celts among the ruins at Hisarlik, and in the British Museum there is a seal-cylinder of jade among the Assyrian and Babylonian relics. The jade ornaments of India must have been brought from central Asia.

See Fischer, *Nephrit und Jadit* (2d ed. Stuttgart, 1881); Meyer's Catalogue of Jade Articles in Dresden Museum (Leip. 1882-83); and Miss Gordon-Cumming's *Wanderings in China* (1885).

Jacl. See DEBORAH.

Jaen, a city of Spain, capital of the province of the same name, is picturesquely situated on a tributary of the Guadalquivir, 50 miles N. by W. of Granada. Its old Moorish walls are fast crumbling away. It is the see of a bishop; the cathedral dates from 1532. Pop. (1884) 21,280. By the Moors the town was called *Jayyenu-Uharir*, 'Jaen of the Silk,' on account of its silk manufactures, for which, however, it is no longer famous.—The province (area, 5184 sq. m.; pop. in 1887, 437,842), part of Andalusia (q.v.), lies wholly within the basin of the Guadalquivir, and is for the most part mountainous. Conquered by the Moors on their entrance into Spain, Jaen maintained its independence as a Moorish state till 1246, when it fell into the hands of Ferdinand III. of Castile.

Jaffa, or JOPPA (Heb. *Yafa*; in New Testament, *Ioppé*; Arab. *Yafa*), a town on the sea-coast of Syria, 53 miles NW. of Jerusalem, of which it was the port in King David's time. Hence Jonah sailed for Tarshish; here Peter had his vision. Under Constantine the place, which had been destroyed by Vespasian, became a bishop's see, and, as the great landing-place of the Crusaders, was taken and retaken by Christian and Moslem. In 1799 Napoleon stormed it and massacred his prisoners; in 1832 it was taken by Mehemet Ali, and restored to the Turks by British help. The open roadstead, the ancient walls, the yellow sand-dunes, and the extensive orange gardens are now the chief features of the brown town on its hillock, which possesses several European consulates; a landing-stage and custom-house were erected in 1888. There is a carriage way to Jerusalem (the toll of which was let for £2000 in 1888), and a railway was opened in August 1892. The population increased from 15,000 to 40,000 between 1883 and 1896, while the export of oranges increased threefold, largely through the German colony of 300 persons established here in 1869. The total exports (wheat and fruit) are worth about £500,000 a year.

Jaffnapatam, a seaport in the extreme north of Ceylon, on an island of the same name, has been peopled by Tamils for more than 2000 years. Pop. (1891) 43,902. A large sprinkling of the European population are of Dutch descent.

Jagatai, a central-Asiatic dialect of Turkish. See TURKS.

Jagellons, the name of an illustrious dynasty which reigned in Lithuania, Poland, Hungary, and Bohemia. The name is derived from Jagello, the last of a line of hereditary grand-dukes of Lithuania, who succeeded to his patrimonial possession in 1381, and was (1386) appointed successor to his father-in-law, Louis the Great, king of Poland and Hungary, in the former of these kingdoms, after having embraced Christianity, and changed his name to Ladislaus II. He was succeeded on the throne of Poland by six kings of his house, the last of whom, Sigismund Augustus, died in 1572. Through a sister of the last, however, the Jagellon

dynasty was continued on the Polish throne till 1668. See POLAND.

Ladislans, the fourth son of the Jagellon Casimir IV. of Poland, was elected king of Bohemia in 1471, on the death of George Podiebrad, and also succeeded Mathias Corvinus in Hungary in 1490. Ladislans died in 1516, and was succeeded in both kingdoms by his son, Louis II., who was defeated and slain by the Turks at Mohacs (29th August 1526), and with whom terminated the Jagellons of Bohemia and Hungary.

Jägerndorf, a town of Austrian Silesia, close to the frontier, by rail 34 miles W. of Ratibor and 18 N.W. of Troppau, has manufactures of woollen cloth, linen, organs, &c. Pop. 14,792. From 1377 there was an independent principality of Jägerndorf; in 1742 its territories were divided between Prussia and Austria.

Jaggery. See DATE PALM.

Jaguar (*Felis onca*), one of the largest and most beautiful of the Felidae, and by far the strongest and fiercest of the American beasts of

Jaguar (*Felis onca*).

prey. The jaguar is nearly equal to the tiger in size, but is less massive, and has shorter legs. The soft, rich fur varies in colour from yellowish-white to very dark brown or black; the sides, shoulders, and thighs are marked with dark ring-like spots, larger, and arranged in more regular patterns than those of the leopard. Each ring usually encloses several small black points. The black-furred jaguar is sometimes regarded as a different species, but the characteristic markings can be seen in certain lights, and the ground-colour varies greatly even in members of the same litter. The jaguar is found all over South America except in some parts of Patagonia, and in North America as far north as the borders of Texas and South California, inhabiting chiefly the outskirts of forests and the shady banks of rivers and lakes. The food of the jaguar is very varied. Wild horses and mules are his favourite prey, but birds, turtles, and fish are readily eaten, while he is often forced to depend for subsistence on the timid, stupid capybaras. The flesh of the peccary, too, is a dainty which he exercises all his ingenuity to procure, for even a jaguar dare not openly attack a herd of these comagous little pigs. His method, it is said, is to conceal himself in a tree till a herd passes, drop down on one and kill it, then spring into the tree again and wait patiently until the angry herd is a safe distance off. The jaguar is hunted sometimes with the lasso, but most frequently with dogs and poisoned arrows, and the skins are imported into Europe in large numbers.

Jahde, or JADE, a bay in the north of Oldenburg, now belonging to Prussia, which has con-

structed a naval station on its shores. See WILHELMSHAFEN.

Jahn, FRIEDRICH. See GYMNASTICS.

Jahn, JOHANN, a Catholic biblical critic, was born at Tasswitz, in Moravia, in 1750. He became professor of Oriental Languages at Olmütz, and, in 1789, at the university of Vienna; but the unwonted boldness of his criticism, as that Job, Tobit, and Judith were didactic poems, and that the New Testament demoniacal possession was the result of natural disease, although not formally condemned, led in 1806 to his honourable retirement to a canonry of St Stephen's, Vienna. He died August 16, 1816. Jahn was an industrious writer, and his *Einleitung ins Alte Testament* (1792), *Archæologia Biblica* (1805; Eng. trans. by T. C. Upham, 1840), and *Enchiridion Hermetice* (1812) were works really remarkable for their time and circumstances. Besides these he published many manuals on the grammar of Hebrew, Syriac, and Arabic, an edition of the Hebrew Bible (1806), and a commentary on the Messianic prophecies (1815).

Jahn, OTTO, a famous archaeologist and philologist, was born at Kiel, June 16, 1813, and studied at Kiel, Leipzig, and Berlin. He next travelled in France and Italy, making a lengthened stay in Rome, and returned in 1839 to lecture at Kiel, whence he was called to Greifswald. In 1847 he accepted the chair of Archaeology at Leipzig, and here he founded an archaeological society, and served as director of an archaeological museum. Deprived in 1851 for his part in the political movements of 1848-49, he became in 1855 professor of the Science of Antiquity, and director of the Academic Art Museum at Bonn, whence he was summoned in 1867 to fill Gerhard's chair at Berlin. He died, however, before entering on his new duties, at Göttingen, 9th September 1869.

Jahn's contributions to archaeology were numberless, and of the first importance. Here may only be named works on Polygnotus, *Die Hellenische Kunst* (1846), *Pytho* (1846); a description of the vases in King Ludwig's collection (1854), and works on the representations of ancient life on vases (1861, 1868); and a work on the evil eye (1850). His works in philology include editions of Persius (1843), Censorinus (1845), Florus (1852), *Pansaniæ descriptivæ Aristicis* (1860), the *Brutus* (1849) and *Orator* (1851) of Cicero, Juvenal (1851), the *Periplus* of Ptolemy (1853), the *Psyché et Cupido* of Apuleius (1856), the *Electra* of Sophocles (1861), the *Symposium* of Plato (1864), and Longinus (1867). Among his numerous other works may be named his elaborate and masterly biography of Mozart (1856-60), a contribution of the first importance to the history of music; *Gesammelte Aufsätze über Musik* (1866); and his *Biographische Aufsätze* (1866).

Jail Fever (known also as Putrid or Pestilential Fever) is now considered to be merely a severe form of Typhus Fever (q.v.), and not a distinct disease. At the present time, owing to improved sanitary regulations, this form of disease is almost unknown; but we learn from Howard's *Account of the State of Prisons* that, in his time, the disease was very frequent in the prisons of England, although unknown in those of the continental countries. In the celebrated Black Assize (q.v.), held at Oxford in 1577, there is no evidence that the disease prevailed among the prisoners, and yet it broke out among the persons present at the trial. So late as May 1750 the lord mayor, an alderman, two judges, most of the jury, and a large number of spectators caught this disease from attending the assizes at the Old Bailey; and many of those who were infected died.

Jains is the name of a heterodox sect of Hindus, found in most parts of Upper India, numerous more especially to the westward, but also scattered throughout the peninsula. They are important

from their wealth and influence rather than from their number. Their tenets are in several respects analogous to those of the Buddhists (see BUDHISM), but they resemble in others those of the Brahmanical Hindus. With the Buddhists they share in the denial of the divine origin and authority of the Veda. With the Brahmanical Hindus, on the other hand, they agree in admitting the institution of caste, in performing the essential ceremonies called *Sanskritas*, and in recognising some of the subordinate deities of the Hindu pantheon; but they disregard completely all those Brahmanical rites which involve the destruction of animal life.

According to their doctrine, all objects, material or abstract, are arranged under nine categories, called *Tattvas*, truths or principles, of which we need notice only the ninth and last, called *Moksha*, or liberation of the vital spirit from the bonds of action—i.e. final emancipation. In reference to it the Jains not only affirm that there is such a state of emancipation, but they define the size of the emancipated souls, the place where they live, their parts, natures, and numbers.

The principles of faith are common to all classes of Jains, but some differences occur in their duties, as they are divided into religious and lay orders, *Yatis* and *S'ravakas*. The *Yati* has to lead a life of abstinence, taciturnity, and continence; he should wear a thin cloth over his mouth, to prevent insects from flying into it, and he should carry a brush to sweep the place on which he is about to sit, to remove any living creature out of the way of danger; but, in turn, he may dispense with all acts of worship; whilst the *S'ravaka* has to add to the observance of the religious and moral duties the worship of the saints, and a profound reverence for his more pious brethren. The secular Jain must, like the ascetic, practise the four virtues—liberality, gentleness, piety, and penance; he must govern his mind, tongue, and acts; abstain, at certain seasons, from salt, flowers, green fruits, roots, honey, grapes, tobacco; drink water thrice strained, and never leave a liquid uncovered, lest an insect should be drowned in it; it is his duty also to visit daily a temple where some of the images of the Jain saints are placed, walk round it three times, make an obeisance to the image, and make some offerings of fruits or flowers. The reader in a Jain temple is a *Yati*, but the ministrant priest is not seldom a Brahman, since the Jains have no priests of their own.

The Jains fall into two principal divisions, *Digambaras* and *S'ravikambaras*. The former word means 'sky-clad,' or naked, but in the present day ascetics of this division wear coloured garments, and confine the disuse of clothes to the period of their meals. *S'ravikambara* means 'one who wears white garments;' but the points of difference between the two divisions are said to be 700, of which 84 are of paramount importance. In the south of India the Jains are divided into two castes; in Upper Hindustan they are all of one caste. It is remarkable, however, that amongst themselves they recognise a number of families between which no intermarriage can take place.

As regards the pantheon of the Jain creed, it is still more fantastical than that of the Brahmanical sects. The highest rank amongst their numberless hosts of divine beings—divided by them into four classes, with various subdivisions—they assign to the deified saints, which they call *Jina* (whence the usual name of the sect), or *Arhat*, or *Tirthakara*, besides a variety of other generic names. The Jains enumerate twenty-four Tirthakaras of their past age, twenty-four of the present, and twenty-four of the age to come; and they invest these holy personages with thirty-six superhuman attributes of

the most extravagant character. They distinguish the twenty-four Jinas of the present age from each other in colour, stature, and longevity. *Rishabha*, the first Jina of this age, was 500 poles in stature, and lived 8,400,000 great years; whereas *Mahavira*, the 24th, had degenerated to the size of a man, and was no more than forty years on earth. The present worship is almost restricted to the last two Tirthakaras. The old view, endorsed by Professor Weber, was that the Jains are a remnant of the Indian Buddhists who succeeded in maintaining their existence by a compromise with Hinduism. The Jains themselves strongly insist that their faith is older than Buddhism; and Jacobi proves from the Jain texts that Buddhism and Jainism were developed out of Brahmanism by a very gradual movement, Jainism being probably the earlier. Modern Jainism Sir W. W. Hunter describes as 'a religion allied in doctrine to ancient Buddhism, but humanised by saint worship.' In 1881 there were 448,897 Jains in British India.

See Oldenberg, *Budha* (Eng. trans. 1882); Thomas, *Jainism; or the Early Faith of Asoka* (1877); Rhys Davids, *Hibbert Lectures* (1881); Jacobi, *Jaina Sūtras* ('Sacred Books of the East,' Clar. Press, 1885); and for the numerous and beautiful Jain temples, see Fergusson's *Five Temples of India* (1880), and Burgess's *Buddhist and Jaina Caves* (2 vols. 1881-83).

Jaipur. See JEYPORE.

Jaisalmer (*Jaysulmere*), capital of the native Indian state of Jaisalmer, in Rajputana, stands on the edge of the Indian Desert, and was founded in 1156. It has several Jain temples. Pop. 10,965.—The state of Jaisalmer contains an area of 16,447 sq. m., and 108,143 inhabitants.

Jakutsk. See YAKUTSK.

Jalalpur, a town of India, 8 miles NE. of the city of Gujrat in the Punjab, noted for its shawl manufacture; pop. 12,839.—There is another ancient and ruined Jalalpur on the Jhelum River.

Jalandhar. See JULLUNDER.

Jalap, a well-known purgative medicine, is the root of *Ipomoea purga*, a plant of the natural order Convolvulaceae. It is a native of the eastern slopes of the Mexican sierras, growing at an elevation of about 6000 feet. Named from the town of Jalapa, it is a perennial twining plant, with large flowers and a turnip-like root, varying from the size of a hazel-nut to that of a man's fist. The roots when fresh are white and fleshy, and abound in a milky juice. They are dug up at all seasons of the year, and hence one great cause of their variation in size and activity. After being dried the roots are brown and wrinkled externally, of a deep yellowish-gray colour internally, and have the consistence of wood. Their odour is faint and disagreeable, and the taste is nauseous. For use in medicine the roots are finely powdered. Jalap-root contains starch, sugar, lignin, and other ingredients, but the active principle is a resin which is officinal

Jalap (*Ipomoea purga*):
a, the root.

under the name of *Jalapu Resina*. The amount of this resin varies from 12 to 21 per cent. It is extracted from the root by means of dilute alcohol, and consists chiefly of a body called convolvulin. Jalap is a hydragogue cathartic, and may be given alone or in combination with calomel or cream of tartar. It and its preparations are used in constipation, renal disease, and cerebral affections. Its action is limited to the production of severe purgation. Jalap was first used in England about the beginning of the 17th century. The ordinary dose of powdered jalap for an adult varies from ten to thirty grains, a scruple generally acting smartly and safely; for children under a year old the dose is from two to five grains. The dose of the compound powder is double that of the ordinary powder.

Jalapa, capital of the Mexican state of Vera Cruz, is 60 miles by rail NW. of Vera Cruz city. It is situated in a charming and fertile district, in a healthy and temperate climate, 4330 feet above the sea, and is neatly built and surrounded with pleasant gardens. The principal buildings are the old Franciscan monastery (1536), the church of St Joseph, a hospital, and the government offices. Pop. (1888) 14,000.

Jalisco, a state of Mexico, on the Pacific, with an area of 38,840 sq. m. It is traversed by the Sierra Madre, and in great part forms a plateau. The climate is healthy away from the coast. The principal river is the Rio Grande de Santiago; in the south-east is the lake of Chapala (q.v.). Silver and copper mining and agriculture have been the chief industries; but within recent years a number of cotton, woollen, paper, and tobacco factories have been established. Pop. (1879) 983,484; (1895) 1,107,863. The capital is Guadalajara (q.v.).

Jalna, a town and British cantonment in the Nizam's Dominions, India, 210 miles NE. of Bombay. Its fruit is celebrated, being sent to Hyderabad, Bombay, and other large towns. Pop. of town, 6258; and of cantonment, 9933.

Jam. See PRESERVED PROVISIONS.

Jamaica, aboriginally *Xaymaca* ('Land of Springs'), one of the West India Islands, and by far the most important of those belonging to Great Britain, is about 90 miles to the south of Cuba, and stretches between 17° 43' and 18° 32' N. lat., and between 76° 11' and 78° 20' W. long. It is divided into three counties, Surrey in the east, Middlesex in the middle, and Cornwall in the west; its area is 4193 sq. m., or a little more than the three English counties of the same names with Hampshire thrown in. The greatest length is 144 miles; the greatest breadth, 50 miles. Turk's and Cadeo's Islands, as well as the three Cayman Islands, are dependencies of Jamaica. The island is traversed from east to west by the Blue Mountains, which rise to 7400 feet. From this range nearly 120 streams descend to the coasts, but owing to the shortness and steepness of their courses they are not navigable, with the exception of Black River, which affords, for small craft, a passage into the interior for 30 miles. Excellent harbours are everywhere to be found. Incomparably the best of these is Kingston (q.v.) harbour, a deep and capacious basin in the south-east quarter of the island. Jamaica is believed to be rich in mineral wealth, but no minerals are extracted. The chief towns are Kingston (pop. 46,542), the capital, and Spanish Town, formerly the seat of the government (pop. 5019), on the south-east of the island; and Montego Bay (pop. 4863), Savanna-la-Mar (2952), on the south-west, and Edmouthe (pop. 2517). Port Royal, situated at the western extremity of the spit of sand that shuts in the

harbour of Kingston on the south, which, previous to the great earthquake of 1692, was one of the chief cities in the West Indies, is now a place of only 1200 inhabitants, though still a naval station.

The climate varies considerably, falling on an average 1° for every 300 feet in altitude. At Kingston, on the coast, the thermometer is nearly all the year round at 70 during the night and 90 during the day, the mean thus being 80° or 81°; but the heat is tempered by the sea-breezes. A corresponding regularity is observable in the upland regions. On the whole, the island is very healthy; invalids even come from the United States to enjoy the benefit of the salubrious air of the interior.

There are two rainy seasons, one in the middle of spring and the other towards the middle and end of summer. In the latter the rains are exceptionally heavy; violent thunder-storms are frequent, and hurricanes sometimes occur. A cyclone in 1880 did damage to the extent of more than a million sterling.

The vegetation is very luxuriant. The primeval woods are rapidly disappearing; yet there are still many valuable trees, such as balata, mahogany, logwood, lignum vite, fustic, ebony, pimento, cocoa-nut and other palms, cactuses, &c. Tropical fruits are grown in great variety, also many of the fruits of more temperate climes. Fruits were exported to the value of £347,652 in 1888 (£39,451 in 1878). Spices, dye-woods, medicinal plants, and food plants, such as ginger, cochineal, castor-oil, arrowroot, maize, vanilla, pimento (all-pee), &c., are extensively grown. A large extent of the cultivated area (one-fifth) is devoted to the growing of Guinea grass. This and pasture land occupy the greater portion of the north and west of the island. In the south and east the principal crops are sugar (33,600 acres in 1888, 12,800 less than in 1878), coffee, vegetables, and fruits. A little cinchona and cacao are also grown. The mongoose, imported to prey on the rats that infested the sugar estates, has, after exterminating the rats, become a plague, and has nearly extirpated lizards, harmless snakes, and small birds, so that insect pests (especially the troublesome ticks) abound. The negroes, who are mostly small holders, are the chief growers of fruit. The exports, which consist chiefly of dye-woods, fruits (oranges, lemons, bananas, pine-apples, &c.), sugar and rum, coffee, ginger, all-pee, and cocoa, average fully 1½ million annually; whilst the imports, consisting of food-stuffs, clothing, hardware, liquors, coals, building materials, &c., reach pretty nearly the same value. About 40 per cent. of the trade is with the United Kingdom, and the share with the United States 43 per cent.

During the past thirty years the white inhabitants have increased far less rapidly in numbers than the black and coloured population. In 1861 the total population was 441,255 (13,816 white and 427,439 black and coloured); in 1871 the figures were respectively 506,154 (13,101 and 493,053); and in 1881, 580,801 (14,432 and 551,132, besides

Chinese and others, and 11,016 immigrant coolies). In 1891 the population had increased to 639,491. By religion 32,300 belong to the Church of England, 30,000 are Baptists, 22,000 Methodists, 10,800 Presbyterians, 9290 Roman Catholics, 16,000 of the Moravian Church, and 9900 of other churches—children being excluded. In 1895 there were 924 government schools, with 98,359 pupils; besides two government training colleges for teachers. Secondary education is left to private initiative. Jamaica has 185 miles of railway and 950 miles of telegraph. The total exports in 1896 had a value of £1,470,241; the imports of £1,856,378. The defences of the island include a British garrison (the West India regiments) of more than 1000 men, a volunteer force of 600, and numerous coast batteries. There is also a semi-military police force of about 700 men. The public debt of the island amounted to £2,220,089 in 1896. The government is in the hands of a governor appointed by the Queen, assisted by a privy-council (which fulfils the offices of an executive) and a legislative council, both partly elective, partly nominated by the Queen or the governor.

Jamaica was discovered by Columbus in 1494, and definitely taken possession of by the Spaniards in 1509. The original inhabitants were peace-loving Indians (not Caribs); but they were practically extinct in 1655, when the island was conquered by the English, an expedition having been sent out for that purpose by Oliver Cromwell, under Admiral Penn and Venables. Jamaica was formally ceded to England by the treaty of Madrid in 1670. The place of the native Indians was taken by negro slaves, imported by the Spaniards, and by Irish and colonial immigrants, who arrived soon after the capture of the island. During the 18th century more than half a million slaves were brought over from Africa. Under English rule the chief events in the history of Jamaica were frequent rebellions of the Maroons, a community of runaway slaves, who had obtained a tract of land on the north side of the island; in 1831-32, a negro insurrection; and on August 1, 1834, the emancipation of the slaves, Jamaica receiving £6,161,927 as her share of the compensation money. The chief result of this last event was to ruin the sugar-growing of Jamaica, principally owing to the difficulty of procuring labour. The negroes refused to work, now they were free. The liberation was followed by concessions of representative and constitutional rights to the newly-liberated slaves. But the experiment proved a failure. The negroes considered it a grievance that offices in the magistracy were not more frequently conferred on them. They wished to suppress coolie immigration, which tended to keep down wages. They sought to obtain land without rent. The more violent even suggested the expulsion of the whole white population of the island. In 1865 the discontent was at its height. In October of that year the negroes rose in revolt and massacred twenty-three whites. Martial law was proclaimed by Governor Eyre, who suppressed the rising with resolute vigour, though the punishments inflicted on the rioters were in some cases perhaps unnecessarily severe. For the course he had taken Governor Eyre was thanked by the Jamaica Assembly; but in England a different view was taken of his conduct (see EYRE). He was recalled, and the representative constitution was suspended. A new constitution was framed in 1866, under which the island is now governed like an ordinary crown colony. There seems to be good authority for the statement that from the catastrophe of 1865 a new life has sprung. Crime has diminished; and education has everywhere advanced among the black population. A collection of Jamaica products was exhibited

with very satisfactory results at the Philadelphia Exhibition of 1876; and an exhibition in Jamaica of native products was opened in the autumn of 1890. New roads have been formed, harbours are being constructed, and the Rio Cobre irrigation canal, begun in 1872, will give fertility to 50,000 acres of the plain between Spanish Town and Kingston. Thanks to the Cuban refugees who have taken several of the long-forsaken sugar estates, property is looking up, and the official statements show that the export trade is increasing, though slowly. Although Jamaica has not recovered its former commercial prosperity, the negroes cannot now be described as idle. They cultivate their provision grounds with care, and are especially active in developing the fruit trade. Extreme poverty is unknown among them, and they are described as a law-abiding and inoffensive community. See the *Jamaica Handbook*, issued at the government printing-office, Kingston; and *Harpur's Magazine*, 1890.

Jamaica Pepper. See PIMENTO.

Jambusar, a town of British India, presidency of Bombay, is situated 30 miles SW. of Baroda. Pop. 11,479. Cotton is prepared for export.

James, the name of at least three persons who took an active part in the foundation of the early Christian church: (1) James the Elder, son of the fisherman Zebedee and brother of John, one of the three chief among the twelve apostles, put to death by the sword under Herod Agrippa, 44 A.D. His day falls on July 25; in the Greek Church, on April 30. According to a baseless legend he journeyed to Spain; whence, as Santiago, he is revered as the patron saint of that country. (2) James the Younger (the Little, not the Less), son of Alphaeus, was likewise an apostle, and is honoured in the Greek Church on October 9; by the Catholics, along with Philip, on May 1. (3) James the Great, the eldest among the 'brethren' of Jesus, according to Josephus (*Ant.* xx. 9, 1) was stoned to death by command of the high-priest Ananus in 62 A.D., during the interval between the departure of Festus and the arrival of a new procurator. The last is identical with the James mentioned in Acts xii., xv., xxi., and Gal. i. 19, who was the head of the Christian community of Jerusalem, and, according to Hezequias, bore the surname of the Just. His day falls in the Greek Church on October 23. Most theologians consider him the author of the epistle which bears his name, although it has been ascribed to both the others, to the son of Zebedee so late as 1876 in an able commentary by the Rev. F. T. Bassett.

The Epistle of James stands first among the *catholic* epistles, and is a kind of encyclical addressed in the first place to the twelve tribes which are scattered abroad, to the Jews of the Dispersion. It was written by a Jew for Jewish readers, all of whom are supposed to be subject to the Jewish law, and it was undoubtedly written early, perhaps about 50 A.D. at latest, certainly before the destruction of Jerusalem. It cannot, however, be proved, though generally assumed, that the epistle must have been written before Paul's first missionary journey, or before the Apostolic Council. Those who read into it a desire to counteract the effects of a misconstruction of St Paul's doctrine of justification by faith of course demand, as will be seen, a later date. The epistle was not admitted into the canon without some difficulty, and it is not much quoted by the earlier writers, Origen indeed being the earliest we find quoting it by name. Eusebius places it in his list of books controverted but

recognised by most (*Antilegomena*), and Jerome expresses the doubt more strongly still. Clement of Alexandria is silent about it, as also is Tertullian, nor is it mentioned in the Muratorian Fragment. But it was early acknowledged by the Syrian Church, and it is found in the Peshito; while there is abundance of less direct proof, as we find startling parallels and coincidences too numerous to be accidental in *The Shepherd* of Hermas, the Epistle of Clemens Romanus, and Irenæus. It was finally declared canonical by the third Council of Carthage (397), and already we find it acknowledged by Cyril of Jerusalem, Epiphanius of Cyprus, Athanasius, Gregory of Nazianzus, and all later theologians, down to the time of the Reformation, when it was rejected by Erasmus and Cardinal Cajetan, and stigmatised by Luther as 'a downright epistle of straw . . . with nothing evangelical about it,' from its supposed contradiction to his fundamental Pauline dogma of justification by faith alone. Calvin disputed this judgment, and maintained that the epistle was not unworthy of an apostle.

The aim of the epistle is throughout ethical rather than doctrinal, Christianity being prominently put forward as the ethical fulfilment of the law, the perfect man being he whose faith has constantly proved itself in practice, and who is patient under all tribulation. It echoes closely the language and method of Christ himself; as Beyschlag says, 'essentially it is the teaching of Christ,' and thus there is little teaching about Christ. Besides the discourses of the Master, especially his Sermon on the Mount, we find distinct traces of familiarity with the *Wisdom of Solomon*, and the *Ecclesiasticus* of the son of Sirach. Formalism, greed of gain, respect of persons, falsehood, evil-speaking, boasting, wrangling and bitterness in debate, attention to dogmatic definitions instead of holiness of life—such are the sins against which the author inveighs with vivid and abrupt invective. His Greek is unusually pure, and some scholars, as Schmidt, Bertholdt, and Bishop Wordsworth, have supposed that the epistle was first written in Aramaic and afterwards translated.

The passage in the second chapter (14-26) has been interpreted by many theologians as a direct attack on the Pauline view of faith and justification, that Christ by his death had accomplished a new order of salvation, in which the law, which was merely temporary, was now abrogated, and that thus Christianity had fitted itself to become a universal religion. But the undoubted difference of tone is rather that of a different point of view than of conscious contradiction, and had the writer had Paul's epistles before him we might well have expected that he would have said much more. Indeed the whole treatment suggests want of acquaintance with Paul's epistles far more than a criticism of his doctrine, and the works required by James are not at all the works of the law condemned by Paul. Paul's conception of faith is a complete spiritual communion with the Redeemer, effected by the free gift of God, in consequence of a profound conviction on the sinner's part of the saving merits of Christ's death, the source of a new holy life in Christ and of love at once to God and man. To James, again, faith is an assent of the thinking mind to the oneness of God and the Messianic work and vicarious sacrifice of Christ, a preliminary condition indeed of justification and eternal salvation, but yet something still to be made perfect by the good works which are the outward fruit of inward love. Good works are an external addition to faith, uniting with it and completing it, regarded as a necessary corollary to justification, rather than, as with Paul, a spon-

taneous and visible fruit of the conscientiousness of a completely new relation to God attained through an antecedent justification. To Paul, says Weiss, this is an act of grace in which righteousness is imputed to the sinner; to James, the act of a judge who by a judicial decision attests the righteousness as proved (Matt. xii. 37), and thus procures deliverance from destruction. Paul's conception is more philosophical and comprehensive, but it by no means excludes the conception of James, which is at once earlier in time and adapted in the first instance to a narrower circle of readers. Paul's emphatic definitions were meant to oppose the Judaizing party, who would have narrowed the largeness of Christian liberty by emphasising the necessity for the works of the Mosaic law; James meant to strike at the lingering Jewish notion that to be a child of Abraham was the most important consideration, and that besides this an intellectual assent to the special claims of Christ was sufficient. His faith without works is not Paul's justifying faith at all, but the profitless faith without love condemned in I Cor. xiii.

The Tübingen school, as might have been expected from its central assumption of an early opposition between the Jewish and Gentile parties in the Christian church, claimed the Epistle of James as a polemic against Paul, and made its author a pseudonymous writer of later time, who employed the name of James as an accepted type of spiritualised Jewish Christianity. Schwegler elaborated this view of the epistle much more fully than Baur himself, regarding it as a parallel to the Clementine Homilies. He makes the antithesis between rich and poor in the epistle refer to secularised Pauline Gentile Christianity, as contrasted with primitive Christian Ebionism, and further reads into the epistle polemical references to Gnosticism and the persecutions of the time of Trajan. Hausrath refers it to the same period, and considers it a direct answer of Jewish Christianity to the Epistle to the Hebrews. Hilgenfeld, again, pushes it back to the time of Domitian, explaining the wisdom attacked as Paulinism which had thrown the church into disunion by its doctrinal disputes, and the Christianity of the writer as Essene and Orphic in character. Holtzmann declares for the same date, maintaining the dependence of the epistle on the Pauline epistles together with the Epistle to the Hebrews and the Apocalypse, on the first Canonical Gospel, First Peter, and the Epistle of Clement, and explaining the rich as distinguished aspirants to Christianity. Similarly Von Soden places the epistle in the time of the Domitian persecutions, and pronounces the author, whom with Holtzmann and others he transfers to Rome, as of a kindred spirit with Clement and Hermas.

Besides the general introductions of Bleek, De Wette, S. Davidson, Hilgenfeld, Holtzmann, Salmon, Dods, and Weiss, and the works on the New Testament canon by Kirchofer, Overbeck, Westcott, and Zahn, may be consulted the special commentaries by P. T. Bassett (1876), Reuss (1878), Erdmann (1881), Schegg (1883), E. H. Plumptre (1884), Beyschlag (1888; 5th ed. of the com. in the *Ecce. Handbuch*); R. Johnstone (2d ed. 1888); and J. B. Mayor (1893). The question of the Brethren of the Lord is discussed under JOSEPH.

James I., king of Scotland (1406-37), the second and only surviving son of Robert III., was born at Dunfermline in 1394. His education was entrusted to the learned Bishop Wardlaw of St Andrews. His elder brother, David, Duke of Rothesay, a reckless and dissipated youth, had died at Falkland—it was strongly suspected, but not proved, a victim to the unprincipled ambition of his uncle, the Duke of Albany, and King Robert

resolved in 1406 to send his younger son for safety to France. But, though a truce at that time existed between England and Scotland, the vessel in which the young prince had embarked was seized by an English cruiser, and James and his attendants were carried to London, and committed to the Tower. He was detained a prisoner in England for the long space of eighteen years, no doubt with the connivance of the Duke of Albany, on whom the government of Scotland had devolved on the death of Robert III. in 1406. Henry IV. made some compensation for his cruel injustice to the young prince by carefully instructing him in all the knightly accomplishments of the age, and he not only became distinguished for his dexterity in martial exercises, but he could play well on the lute and harp and other musical instruments, was a skilful calligrapher, illuminator, and painter in miniature, and had also a considerable knowledge of medicine. On the death of the Duke of Albany in 1420, his son Murdoch succeeded to the regency. Under his feeble rule the country fell into a state of disorder, almost of anarchy, till at length Murdoch himself grew weary of his position, and took steps to procure the return of the lawful sovereign. The conditions of his release were definitely arranged May 12, 1423. It was stipulated that £40,000 was to be paid to defray the expense of his maintenance and education. James had in a singularly romantic manner gained the affections of Jane Beaufort, a daughter of the Earl of Somerset, niece of Richard II., and granddaughter of John of Gaunt; and on February 12, 1424, they were married with all the pomp befitting the occasion. The royal pair then set out for Scotland, and were welcomed with joyous acclamations.

James found his kingdom a scene of lawless excess and rapine, mainly owing to the weakness of the government and the turbulence of the nobles. He at once set himself to restore the legitimate authority of the crown, and to rescue the commons from oppression and plunder; but in carrying out these praiseworthy objects he sometimes lost sight of both mercy and justice. Eight months after his restoration he suddenly swooped down upon his cousin the former Regent Albany, two of his sons, and his aged father-in-law, the Earl of Lennox. They were brought to trial, but the nature of the charges against them is not known. They were found guilty and executed amid general compassion and regret; the people believed that it was simply an act of cruel revenge. James then seized and imprisoned fifty of the Highland chiefs, and put to death the most obnoxious ringleaders. He deprived the powerful Earl of March of his estates, and on the death of the Earl of Mar, the victor at Harlaw, he seized the earldom and annexed its immense estates to the crown. Meanwhile, into the parliament he introduced the principle of representation, and for the first time caused its acts to be published in the language of the common people. Its enactments, which were judicious and enlightened beyond the age, comprehended the subjects of agriculture, commerce, foreign and domestic manufactures, the regulation of weights and measures, the impartial administration of justice, and the police of the country. He renewed commercial intercourse with the Netherlands, and concluded a satisfactory treaty with Denmark, Norway, and Sweden. He drew closer the ancient bond of alliance with France, and gave his eldest daughter in marriage to the Dauphin. But he unfortunately persisted in carrying out harshly, and sometimes unjustly, his measures for curbing the power of the nobles, which excited not without cause strong discontent and apprehension among the whole body.

His confiscation of the earldom of Strathearn,

which had devolved on Patrick Graham, brought matters to a crisis. A conspiracy was formed against the king's life, headed by his uncle, the Earl of Athole; Sir Robert Stewart, his grandson; and Sir Robert Graham, uncle of the Earl of Strathearn, who had personal as well as family injuries to revenge. The plot was carried into effect at Perth on the 20th of February 1437. The king was about to retire for the night, when there was a great noise and clashing of arms heard, and a band of assassins led by Graham broke into the monastery of the Dominicans where the court was residing. The bolts had been removed from the chamber door, but Catharine Douglas heroically thrust her arm into the staple. It was instantly broken, and the ruffians burst into the chamber. The king, who had sought refuge in a vault under the floor, was discovered, and after a desperate resistance was cruelly murdered. The murderers were all apprehended in less than a month, and put to death by tortures shocking to humanity. By his wife, the heroine of the *Kingis Quair*, he left one son (his successor) and five daughters, one of whom, Marguerite d'Ecosse, dauphine of France, was a gifted poetess. James was unquestionably the ablest of the Stewart sovereigns, and was possessed of high poetical genius. His principal poem, entitled *The Kingis Quair* (i.e. the king's quire or book), is remarkable for elegance of diction and tender delicacy of feeling. The humorous pieces *Christ's Kirk on the Green* and *Pebblis to the Play* are much later compositions; but a 'Ballad of Good Counsel,' written, unlike *The Kingis Quair*, strictly in the Scottish dialect, is ascribed by Professor Skeat to James. See Professor Skeat's edition of *The Kingis Quair* (Scottish Text Soc. 1884), and Rossetti's noble ballad, 'The King's Tragedy.'

James II., king of Scotland (1437-60), was only six years old at the time of his father's murder. So alarming was the aspect of affairs that the queen-mother deemed it necessary to take shelter with her son in the castle of Edinburgh. Along with Sir Alexander Livingston of Callendar she was entrusted with the care of the young king; but Sir William Crichton, who was appointed Chancellor, and was governor of Edinburgh Castle, kept possession of his person, until the queen contrived to convey her son out of the fortress concealed in a chest, and took refuge with Livingston in Stirling Castle. Crichton was besieged in his stronghold, and compelled to make his submission. Meanwhile the country was brought to the verge of ruin by the feuds of the nobles, and the death of the Earl of Douglas in 1439 removed the only restraining power. Livingston availed himself of the marriage of the queen-dowager to Sir James Stewart of Lorn to compel her to resign her office as guardian of the king. Crichton and Livingston became reconciled, and were now the sole rulers of the kingdom, till in 1449 the young king assumed the reins of government. He displayed great prudence and vigour in the management of public affairs, and inflicted condign punishment on the Livingstons for their treatment of his mother.

The truce which had for some years existed between England and Scotland expired in 1448, and war was renewed on the Borders. Peace, however, was restored in the following year by the conclusion of a permanent truce. In June 1449 James married Mary, the only daughter of Arnold, Duke of Gueldres. He procured from the parliament a number of judicious enactments for the repression of outrages, the impartial administration of justice, the protection of the tenants of the feudal barons from summary ejection from their lands, and for the punishment of marauders. But his efforts to

promote the social welfare of the people were greatly obstructed and thwarted by the nobles, and especially by the Douglasses (see DOUGLAS); Earl William bent his whole energies to obtain pre-eminent position and power, and he entered into a treasonable bond with the Earls of Crawford and Ross. James invited him to the court at Stirling, and earnestly urged him to withdraw from his engagement with Crawford and Ross. Douglas in a haughty and insolent manner refused to comply with this request; and the king, whose temper was naturally fiery, lost all self-command, and stabbed the earl with his dagger. Some of the courtiers pierced his body with twenty-six wounds. After this atrocious murder the friends and vassals of the earl made war on the king until, by liberal promises of land and honours, Lord Hamilton and other powerful nobles were induced to abandon their cause; their estates were then forfeited, and they were compelled to take refuge in England. James was so irritated at the conduct of the Yorkist faction in protecting and pensioning the exiled Douglasses that he unwisely suffered himself to be entangled in the contest between the rival houses of York and Lancaster, and marched for England in 1460 at the head of a powerful army. He laid siege to Roxburgh Castle, which was at that time in the hands of the English, and was killed by the bursting of a cannon.

James III. (1460-88), born 10th July 1451, succeeded James II. in 1460. The guardianship of the young monarch was entrusted to his mother and Kennedy, Bishop of St Andrews, a prelate of great sagacity and integrity, while the Earl of Angus, chief of the 'Red Douglasses,' was made lieutenant-general. Under their management the government of the kingdom was carried on judiciously and successfully; but the death of the earl in 1462 and of the bishop in 1466, while the king was still a boy, left the country a prey to the factious and ambitious nobles, conspicuous among whom was Lord Boyd, high justiciar. Lord Boyd's son was created Earl of Arran, and in 1467 he obtained the hand of the king's sister, the Princess Margaret. The ambition and arrogance of the family, however, led to their downfall. The Earl of Arran fled to the Continent; and after his death, which took place apparently before 1472, the Princess Margaret married Lord Hamilton (1474), whose descendants became by this alliance the nearest heirs to the crown. When the king reached manhood the defects of his character became apparent. He had a refined and cultivated mind and fine tastes, was fond of mathematics and of music, and possessed great skill in architecture; but he was quite unfit to rule a country like Scotland at that period and to keep in order its rude and turbulent nobles. He was fond of money and of pleasure, and spent his time in the society of architects, painters, and musicians. The nobles were indignant at the slight thus put upon them, and attached themselves to the king's brothers, the Duke of Albany and the Earl of Mar, who were distinguished for their courage and skill in military exercises. James became jealous of their popularity and put them in prison, whence Albany escaped to the Continent, but Mar died in confinement. Albany had, in fact, aspired to the crown and had engaged to hold it as the vassal of Edward, king of England. In retaliation for an invasion of the country by an English fleet, James summoned the array of the kingdom to make an inroad into England. The army had advanced as far as Lauder when the disaffected nobles suddenly seized the royal favourites and hanged them on a bridge over the river Leader—Angus obtaining the name of Bell-the-Cat from his boldness in taking the initiative. Returning to Edinburgh, they committed the king a close prisoner to the castle of

Edinburgh. A reconciliation was effected between the king and his brother, but it was of short duration. The conspiracy among the nobles was speedily renewed. They rose in open rebellion, and induced the young heir to the throne to become their nominal head. The king was supported by the northern barons, but they were greatly outnumbered by the rebels. An encounter took place between the two bodies (11th June 1488) at Sauchiehall, about a mile from the famous field of Bannockburn. When the battle was going against the royalists the king galloped from the field, but was thrown from his horse at Beaton's Mill, and murdered. James left by his queen, Margaret of Denmark, three sons, the eldest of whom succeeded to the throne.

James IV. (1488-1513) was born in 1473. He was only in his sixteenth year when he was induced to join the disaffected barons in their rebellion against his father, but there is no reason to believe that he was a mere passive tool in their hands. The remorse which he felt on learning of his father's murder, shown by his wearing an iron chain round his waist and submitting to various other austerities by way of penance, affords conclusive evidence of his consciousness of guilt. His confederates in the rebellion, as might have been expected, turned their victory to their own advantage. They took possession of all the most important offices of state, of the money in the royal treasury, and of the late king's jewels. They had even the effrontery to accuse the loyal barons of treason, and to deprive them of their estates, which were divided among the leading conspirators.

When the young king reached maturity he exhibited great energy and good sense in the administration of public affairs, in vindicating law and punishing crime, in encouraging shipbuilding, and in developing the agriculture and manufactures of the country. He gradually withdrew his confidence from the barons who had used him as a tool to gain their own selfish ends, and transferred it to Sir Andrew Wood (q.v.) and other trustworthy counsellors. James vigilantly guarded against the encroachments of the papal court, and firmly asserted the ecclesiastical independence of his kingdom. His romantic and rash disposition induced him to support the cause of the impostor, Perkin Warbeck, who visited Scotland in 1495, and to invade England in his behalf. However, in 1497 a truce for seven years was concluded between the two kingdoms, and in August 1503 the Scottish king was married to Margaret, eldest daughter of Henry VII.—an alliance which led ultimately to the union of the crowns. James's affable manners, frank disposition, and splendid hospitality made him highly popular among his subjects, and his friendship was courted by foreign sovereigns. Henry VIII., who ascended the English throne in 1509, joined the league against France, while James adhered to the ancient alliance with that country. Petty disputes arose between the borderers of the two countries, and inroads were made on both sides. James was indignant at the capture of two privateers commanded by the famous Andrew Barton, who fell in an engagement with two English men-of-war, and all redress was refused by Henry. The French king, hard pressed by the Spanish and English armies, made strenuous efforts to obtain assistance from the Scots, and the French queen addressed a letter to James calling herself his mistress, and entreating him for her sake to advance three feet into English ground. He was unfortunately induced to comply with her request, and, disregarding the entreaties of his queen and the remonstrances of his counsellors, he summoned the army of his kingdom and invaded England in the summer of 1513. He lingered about the Borders until the Earl of Surrey had collected a powerful army to repel the invasion. A

battle took place at Flodden (q.v.), 9th September, in which the Scottish king and the flower of his nobility and gentry lost their lives. James possessed excellent abilities and great accomplishments, but he was headstrong, obstinate, and impatient of contradiction, licentious, fond of pleasure, and profuse in his expenditure. See Gregory Smith's *Days of James IV.* (1890).

James V. (1513-42), who was born on the 10th of April 1512, ascended the throne at a most critical period; for, though contrary to expectation the Earl of Surrey did not invade Scotland, the kingdom was torn by intestine feuds between rival factions. The queen-dowager, headstrong and passionate, was appointed regent. About eight months after the king's death she gave birth to a son, who died in infancy; and four months later she married the young Earl of Angus, head of the Douglas family. Her marriage put an end to her regency, and the Duke of Albany, son of the younger brother of James III., was invited from France and chosen in her room. Amid the contentions of the rival French and English factions, and the private quarrels of the nobles, the country was reduced to a state of almost total anarchy. The intrigues of Henry contributed not a little to foment the prevailing disorders. Albany, who insisted on revisiting France, returned after the lapse of a few months to find the Hamiltons and Douglasses at open war; and, after vain efforts to assert the authority of the government, he obtained permission in the beginning of 1524 to revisit France for a limited period, but did not return. Meanwhile the young king had been placed under the care of the poet Sir David Lyndsay, who instructed him in all manly and liberal accomplishments; but his mother interrupted his education, and, with the assistance of her brother Henry VIII. in 1524, when James had reached his thirteenth year, put him at the head of the government in order that she and her faction might misgovern the kingdom in his name. She had now become tired of her husband, and after a good deal of difficulty she succeeded in obtaining a divorce from him, and married young Henry Stewart, a son of Lord Avondale. In the following year the custody of the young king fell into the hands of the Douglasses, who kept him a close prisoner until he made his escape in 1528, and assumed the position of an independent sovereign. He displayed great firmness and resolution in carrying out his judicious policy, though unfortunately his morals had been deeply injured by the manner in which the base sycophants of the court had pandered to his passions. He expelled from the kingdom the Douglasses, who had entered into a traitorous league with England, severely punished the Border freebooters, chastised the insurgent Highlanders, renewed the ancient commercial treaty between Scotland and the Netherlands, instituted the College of Justice, and took measures to protect the peasantry against the tyranny of the barons. His sympathy with the common people and his habit of visiting their houses in disguise procured for him the designation of 'the king of the commons.' In 1536 James undertook a voyage to France, and on the 1st of January 1537 he was married to Magdalene, daughter of Francis I., who, however, died in the following July. In June 1538 James married Mary of Guise, widow of the Duke of Longueville and sister of the Duke of Guise.

Meanwhile the principles of the reformed faith were making progress in Scotland, and Henry VIII. tried to induce his nephew to follow his ecclesiastical policy and to repudiate the authority of the papal see. But James, though he looked with a severe eye upon the overgrown wealth, idleness, and corruption of the clergy, found it necessary to rely on their

support in order to reduce the exorbitant power of the nobles. The bishops on their part strove to bring about a rupture with England. With the hope of gaining over his nephew to adopt his policy, Henry invited the Scottish king to meet him at York in the autumn of 1541, and waited there six days for him. But James was induced to break his engagement, and the proud temper of the English monarch fired at the insult. Other causes of offence arose, and war broke out between the two countries in 1542. An army of 30,000 men under the Duke of Norfolk were ordered to invade Scotland; but the attempt ended in nothing. A Scottish army levied to oppose the invaders advanced as far as Fala; the nobles, however, while willing to support James within the kingdom, refused to follow him beyond the frontier. Another army was shortly after levied by the exertions of the clergy; but the command of this army having been unwisely given by the king to a favourite named Oliver Sinclair, the nobles again refused to act. While the Scottish army thus disputed, a body of English Borderers fell upon and completely routed them at Solway Moss, taking many prisoners. James was completely overwhelmed by this shameful discomfiture, and fell into a state of the deepest despondency. He retired to Falkland Palace attacked by a slow fever which no skill could remove, and he died there 14th December 1542, in the thirty-first year of his age. He left one legitimate child, the ill-fated Mary, who was only a few days old at his death, and six natural children, one of whom was the celebrated Regent Moray. See Bapst, *Les Mariages de Jacques V.* (1889).
